The Role of the Locus Coeruleus—Limbic Noradrenergic Transmission in the Action of Antidepressant Drugs[1]

Wojciech Kostowski, M.D.,[2] Adam Plaźnik, M.D.,[2] and Wojciech Danysz, M.A.[2]

Results of many studies indicate that the deficit in noradrenergic (NE) neurotransmission is critically involved in the mechanism of at least certain types of depression (Review: Maj et al., 1984; Schildkraut, 1965; Sugrue, 1983; Vetulani, 1984). The clinical effects of antidepressive drugs are, in accordance with NE concept of depression, explained as resulting from enhancing NE concentration in the synaptic cleft due to different mechanisms. There is, however, a controversy as to the acceptance of this explanation. The effect of NE uptake inhibition, which is characteristic for numerous tricyclic antidepressants, occurs immediately after administration of drugs whilst the therapeutic effects appear after several weeks of treatment. Some well-known amine uptake blockers such as cocaine and amphetamine are poor antidepressants. Moreover, clinically effective new or "atypical" drugs lacking NE uptake inhibiting activity have been found (e.g., mianserine, trazodone, or citalopram). These and other controversies prompted numerous investigators to undertake intensive studies on the mechanism of action of chronically administered antidepressants.

The important finding in this field was that of the Sulser group (Sulser et al., 1978; Vetulani & Sulser, 1975; Vetulani et al., 1976) showing that repetitive (but not single) doses of various antidepressants produced a decrease in the cyclic AMP-generating system response to NE in the rats' cerebral cortex and limbic forebrain. That result was subsequently confirmed and extended in other laboratories including the finding that chronic antidepressants and other antidepressive therapies such as electroconvulsive treatment (ECT) not only did reduce sensitivity of NE receptors associated with the cyclic AMP-generating system, i.e., beta receptors, but also in some cases reduced the number of beta receptors. This phenomenon, called beta adrenoceptor "down regulation," was proposed as the common mechanism of antidepressant action (Mobley & Sulser, 1981, for review).

Further studies have revealed that chronic treatment with antidepressants leads to changes in sensitivity and/or density of alpha adrenoceptors belonging to $alpha_1$ and $alpha_2$ subgroups. Radioligand binding studies have demonstrated increased ^{3}H-prazosin (a selective antagonist of $alpha_1$ receptors) binding sites in the rats' brain (Campbell & McKernan, 1982; Vetulani & Pilc, 1982; Vetulani et al., 1983) but the results with another less selective $alpha_1$ ligand—^{3}H-WB4101—were less conclusive (Peroutka & Snyder, 1979). The findings indicating the $alpha_1$ adrenoceptor "up-regulation" are consistent with other studies which reveal that chronic antidepressants may affect behavioral and electrophysiological responses in a manner indicating increasing NE transmission mediated by postsynaptic $alpha_1$ receptors (Maj et al., 1981; Menkes & Aghajanian, 1981). These receptors seem to mediate exitatory signals at electrophysiological level and to mediate stimulatory behavioral effects (Aghajanian, 1984; Maj et al., 1981).

The concept of $alpha_1$ receptor up-regulation is generally in accordance with the "classical" theory of monoamine deficiency in depression and underlies the fact that antidepressant drugs may increase NE output through excitatory $alpha_1$ receptors (Vetulani, 1984).

The third line of receptor studies concerns the role of inhibitory $alpha_2$ adrenoceptors in depression and the mode of action of antidepressants. These receptors located both pre- and postsynaptically play an inhibitory role in NE transmission. Presynaptic $alpha_2$ adrenoceptors are involved in inhibition of

NE release from nerve endings (Starke, 1977), while postsynaptic receptors inhibit bioelectrical activity of neurons (Svensson et al., 1975). An agonist of alpha$_2$ adrenoceptors, clonidine produces well-known signs of behavioral depression such as sedation (Delini-Stula et al., 1979; Kostowski & Malatyńska, 1983), suppression of avoidance reactions (Robson et al., 1978), and inhibition of self-stimulation in laboratory animals (Franklin & Herberg, 1977) as well as synchronization in the cortical EEG pattern (Florio et al., 1975). Results of many recent studies indicate that antidepressants reduce sensitivity of alpha$_2$ receptors. First, clonidine has been found to produce less marked biochemical and behavioral effects in animals receiving repetitive doses of antidepressants (Kostowski & Malatyńska, 1983; Pilc & Vetulani, 1982) and then, chronic administration of antidepressants reduces clonidine-induced synchronization in the EEG pattern (Kostowski et al., 1984a; Passarelli & Scotti de Carolis, 1982). Studies with ^{3}H-clonidine binding revealed less conclusive results, but generally, when antidepressants were administered for sufficiently long periods (3 weeks and more) they tended to reduce the density of clonidine binding sites (Campbell & McKernan, 1982; Pilc & Vetulani, 1982; Smith et al., 1981; Vetulani, 1984).

Studies on the Role of the Locus Coeruleus (LC) System

These and other findings not discussed here suggest that long-acting administration of antidepressants produces multidirectional changes in the brain adrenoceptors. The functional consequences of this phenomenon are, however, not clear. First of all, the knowledge of the physiological role of adrenoceptors, particularly in regulation of behavioral processes, remains only partially elucidated. Further, only a few studies deal with the correlation between receptor sensitivity and/or density and given behavioral phenomena. One approach to elucidate the functional aspects of receptor changes following chronic antidepressive therapy is to study the behavioral effects of selective lesions and stimulations of NE neurons in the brain. Such experiments were initiated several years ago in pharmacological laboratory at the Psychoneurological Institute in Warszawa (Kostowski, 1980, 1981). One line of that study focused on the possible role of ascending NE systems such as the LC and the ventral bundle (VB) in the mechanism of depression and the mode of action of antidepressants. Following biochemical, pharmacological, and behavioral studies in rats with lesioned NE systems the investigators hypothesized that a defect in the LC function might be responsible for depressive symptoms (Kostowski, 1980, 1981). More recently the investigators found that a bilateral lesion of the LC either electrolytic or induced by 6-hydroxydopamine (6-OHDA) markedly reduced characteristic effects of desipramine in two tests commonly used in studies on antidepressants, i.e., clonidine-induced hypothermia and so-called behavioral despair. Chronic but not acute administration of antidepressant drugs has been reported to antagonize hypothermic action of clonidine in rats (von Voiglander et al., 1978). Since clonidine hypothermia is mediated mostly through alpha$_2$ adrenoceptors, the finding that clonidine produces less marked effect in animals pretreated with antidepressants suggested that this treatment may "down regulate" alpha$_2$ receptors (Vetulani, 1984). The other test, more psychologically oriented, is based on the finding that antidepressants reduce the "immobility" of rats and mice submitted to the unescapable forced swim situation (Porsolt et al., 1979). This test is supposed to reflect the effect of drugs upon NE transmission while the drugs acting upon serotonergic mechanisms are less active (Borsini et al., 1981). The behavioral despair (or forced swim) test is sensitive for single doses of antidepressants but some drugs at least, e.g., desipramine (DMI), produce even stronger characteristic effect, i.e., reduce immobility when administered chronically. Interestingly, the action of DMI and amitryptiline (AMI) in clonidine hypothermia tests was abolished by LC lesions (Figure 1) but also following the administration of DSP-4, a new neurotoxin depleting NE concentrations within the areas innervated by the LC system, e.g., the hippocampus and cerebral cortex (Danysz et al., 1985). Both lesions of the LC

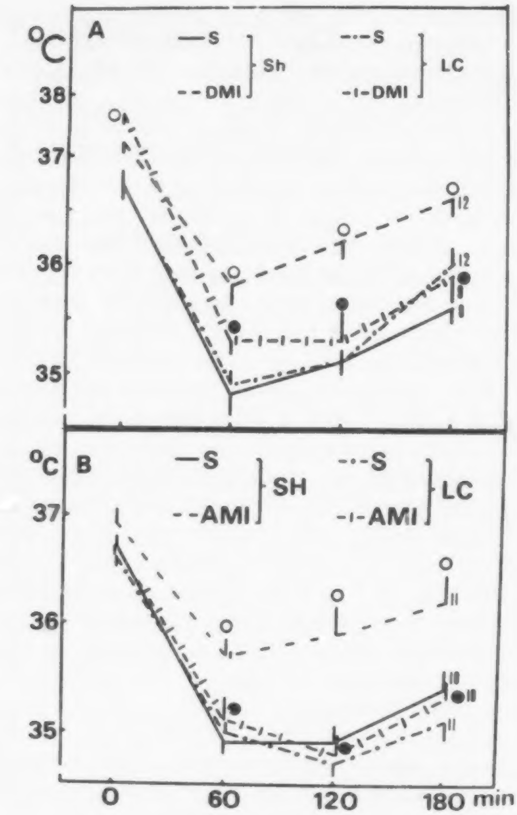

FIGURE 1. Effects of DMI and AMI given chronically (3 weeks, 10 mg/kg i.p. once a day) on clonidine-induced hypothermia (0.2 mg/kg i.p.) in rats with 6-OHDA lesions of the locus coeruleus (LC)(SH = sham-lesioned rats). Mean values SEM, number of animals in each group marked in the figure. Vertical scale: rectal temperature (°C), horizontal scale: time after clonidine injection (in minutes). 6-OHDA was injected bilaterally into the LC (8 µl/µl) 7 days before clonidine (control animals received microinjection of saline). ○ = $p<0.05$ in respect to sham-lesioned saline group, ● = $p<0.05$ in respect to sham-lesioned DMI group (Student's "t" test two-tailed).

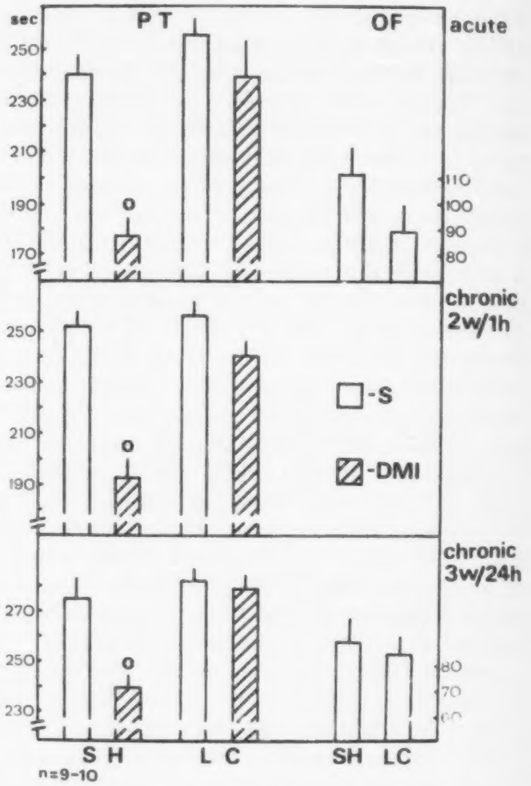

FIGURE 2. Effect of DMI on rats' behavior in the behavioral dispair (forced swim) test. LC = rats with 6-OHDA bilateral lesions of the locus coeruleus, SH = sham-lesioned animals, mean values from 9 to 10 experiments SEM. Upper panel: the animals treated with single dose of DMI (10 mg kg^{-1} i.p.) 7 days after 6-OHDA and then tested 1 hr later in the behavioral dispair (Porsolt) test (PT) (acute treatment). Middle and lower panels: rats treated chronically with DMI (10 mg kg^{-1} i.p. once a day) or saline (S), lesioned and then tested 1 hr after 14th dose of DMI and again 24 hrs after 21st dose of DMI. 6-OHDA lesions were performed on the 7th day of treatment. Both lesioned and sham-lesioned rats (untreated) were tested additionally in the open field (OF) 1 day after PT. Vertical scale = time of immobility in sec (PT) or activity in the OF (number of squares crossed during 5 min of observation). ○ = $p<0.05$ in respect to saline (Student's "t" test, two-tailed). Note that 6-OHDA lesions abolished DMI action in the PT.

and DSP-4 administration were also noticed to prevent the effects of single doses of DMI in the behavioral despair paradigm. The investigators found, moreover, that the effect of chronic (3 weeks) DMI administration on rats' behavior in this test was abolished by a 6-OHDA lesion of the LC (Figure 2). Lesioning of the VB remained, however, uneffective (Danysz et al., 1985; Kostowski et al., 1984b).

Despite the clear-cut effect of LC lesion on AMI action in clonidine hypothermia, the anti-immobility effect of AMI in behavioral despair test remained unchanged following LC lesion. The findings indicate that anatomical integrity of the LC system is critical for DMI action in animal tests commonly used for evaluation of antidepressive effect; it is difficult, however, to ascertain at present whether this hypothesis is true for other antidepressants.

In another set of experiments the investigators found that electrical stimulation of the LC, though not that of the VB, increased the rats' activity in the forced swim (behavioral despair) test, thus producing an effect similar to that brought about by the administration of antidepressants (Danysz et al., 1985; Kostowski et al., 1984b,c). It is of particular interest to note that this effect occurred even after a single stimulation session (30 Hz, 60 minute period of stimulation) and disappeared 24 hours after stimulation (Figure 3). Stimulation of the LC did not produce any behavioral effect in the open field, thus indicating that reduction in immobility was not simply due to an increase in the general activity of rats.

Further study showed that stimulation effect was reduced by pretreatment with phenoxybenzamine, the antagonist of alpha$_1$ adrenoceptors, but not by propranolol, thus indicating that the "antidepressive" effect of LC stimulation was mediated through alpha$_1$ but not beta receptors (Danysz & Kostowski, in press). It is noteworthy that DMI action in the behavioral despair test also could be blocked by alpha$_1$ antagonists (Kitada et al., 1983) but not by propranolol (Danysz & Kostowski, in press) (Figure 4). These results imply the similarity between the stimulation of the LC and DMI action and support our previous hypothesis concerning the possible role of this structure in the mechanism of affective disorders (Kostowski, 1981). It also indicates the role of the alpha$_1$ adrenoceptor system in mediating the antidepressive effect.

Regarding the possible implication of the LC system in both depression and the mode of action of antidepressants, some recent findings from the literature should be mentioned. Interestingly enough, the LC has been found to contain a high density of DMI binding sites (Biegon & Rainbow, 1983). Lesion of this area has been reported to prevent the decrease in beta adrenoceptor sensitivity following long-term DMI administration (Janowsky et al., 1982). Both acute and chronic DMI therapy reduces the firing of LC cells, the chronic treatment, however, prevents the further reduction of firing by the alpha$_2$ ad-

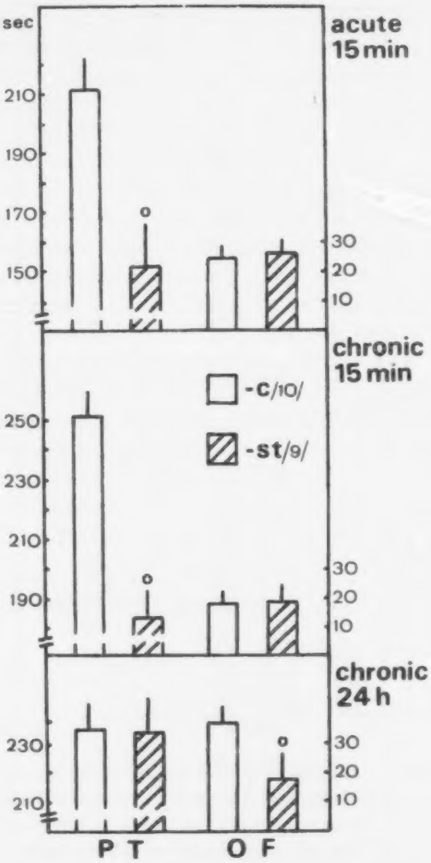

FIGURE 3. Effect of unilateral stimulation of the LC (30 Hz, 2 to 4 V, stimulation session 45 min) on rats' activity in the behavioral despair test (PT) and open field (OF) test. Mean values from 9-10 rats SEM, c = control (unstimulated), st = stimulated. Vertical scale = time of immobility in sec (PT) and activity in the OF (the number of squares crossed during 5 min of observation). Upper panel: the effect of single stimulation session (the rats were tested 15 min after the stimulation in the OF and then immediately in the PT. Middle and lower panels: the same rats were tested 15 min and 24 hrs after 6th stimulation session (one stimulation session daily). ○ = $p < 0.05$ in respect to unstimulated animals (Student's "t" test, two-tailed). Note that stimulation (both single and repetitive) reduced rats' immobility shortly after the stimulation but failed to change the animals' behavior in the PT 24 hrs after the stimulation. Stimulation failed to modulate the rats' activity in the OF 15 min after single session but reduced the activity 24 hrs after the 6th session.

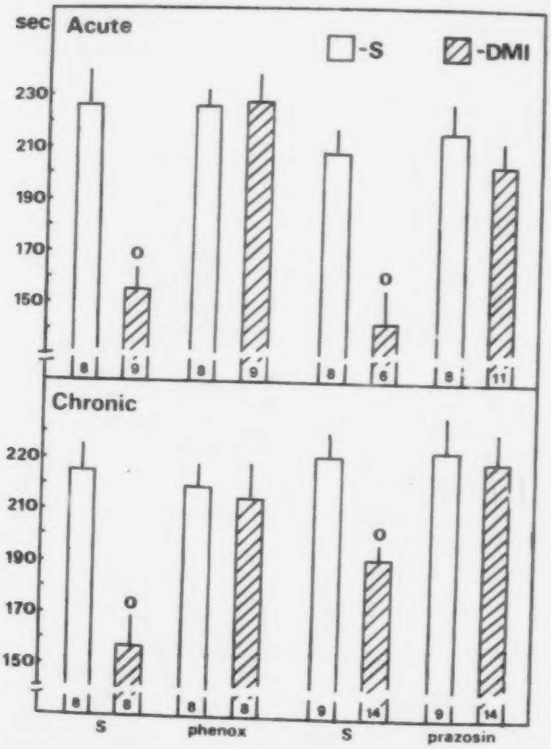

FIGURE 4. Effects of single dose (10 mg kg^{-1} i.p.) and chronic administration (10 mg kg^{-1} i.p. once a day for 3 weeks) of DMI on animals' behavior in behavioral despair test. The animals received 70 minutes before testing single dose of phenoxybenzamine (phenox, 10 mg kg^{-1} i.p.) or prazosin (5 mg kg^{-1} i.p.). In an acute experiment rats were tested 1 hr after DMI while in chronic experiments the immobility was measured 24 hrs after the last (i.e., 21st) dose of DMI. Mean values = SEM (number of rats marked in columns), s = saline group. o = $p<0.05$ in respect to saline.

renoceptor agonist, clonidine (Svensson & Usdin, 1978). Furthermore, Weiss et al. (1981) reported that the time course for the behavioral disturbances induced by unescapable shock in a forced swim task paralleled the NE reduction in the LC more closely than NE alterations on other brain areas.

Possible Role of the Hippocampal NE Transmission

The ascending projection from the LC innervates not only the neocortex but also limbic areas such as hippocampus, amygdaloid complex, and septum (Lindvall & Björklund, 1978). The results of studies upon the LC system prompted the investigators from the Psychoneurological Institute, Warsaw, to analyze the possible role of NE transmission within target areas of this system in the action of antidepressants. Recent experiments focused upon the hippocampus, the structure involved in the regulation of numerous behavioral processes (e.g., emotions, motivations, learning, and memory) which are implicated in phenomenology of depression. This structure has been considered as a promising target area for action of antidepressants for many reasons. First, it contains high density receptor binding sites for ^{3}H-labeled imipramine and desipramine (Sherman & Allers, 1980) and high correlation had been found between imipramine concentration in the rat's hippocampus and positive effect of the drug in the forced swim test. Also, chronic treatment with DMI increased MHPG (3-methoxy-4-hydroxy-phenylethylene glycol, the main NE metabolite in the brain) concentrations in the hippocampus (Miyauchi et al., 1982) as well as the basal firing rate of rat hippocampal neurones (Huang, 1979). Furthermore, the investigators found that DMI was able to produce the "antidepressive" effect in the behavioral despair test when injected into the dorsal hippocampus (Danysz & Kostowski, in press), while extensive electrolytic lesions of the structure completely abolished the effect of drug in this test (A. Plaźnik, personal communication).

The investigators attempted, therefore, to study the effects of agonists of alpha and beta adrenoceptors injected intrahippocampally and to assess the possible changes in their actions after single and multiple doses of antidepressants. Microinjections of NE increased rats' activity in the open field (Plaźnik et al., 1983) and activated the animals in the forced swim (behavioral despair) situation. The effect must have been mediated through both $alpha_1$ and beta receptors since it was attenuated by phenoxybenzamine as well as by propranolol (Plaźnik & Kostowski, in press). A single dose of DMI (10 mg kg^{-1} i.p.) failed to modulate NE action but chronic treatment (3 weeks) markedly potentiated NE effects in both tests mentioned above (Plaźnik & Kostowski, in press; Plaźnik et al., 1984). Both phenylephrine, a selective alpha$_1$ adrenoceptor agonist, and isoprenaline, an agonist of beta receptors, when given in sufficient doses also produced stimulatory effects but only phenylephrine action was potentiated by chronic (but not acute) treatment with DMI (Figure 5). A microinjection of clonidine reduced rats' activity in the open field but failed to produce significant change in the animals' behavior in behavioral despair situation. In rats chronically treated with DMI, clonidine uniformly activated the behavior in both experimental paradigms (Plaźnik & Kostowski, in press; Plaźnik et al., 1984).

The results indicate that chronic desipramine potentiates behavioral phenomena mediated through hippocampal alpha$_1$ receptors and attenuates or even reverses, as in the open-field, inhibitory effects mediated through hippocampal alpha$_2$ adrenoceptors. Interestingly enough, behavioral effects associated with beta adrenoceptors remained unchanged following DMI. This finding indicates the apparent involvement of behavioral effects mediated through the alpha, though not beta, hippocampal adrenoceptors in the action of long-term DMI. This finding, although not supporting the functional role of beta adrenoceptors in the action of antidepressant drugs, is generally in agreement with the results of other authors showing hypersensitivity and increased density of alpha$_1$ adrenoceptors following antidepressant therapy and with those stressing the reduced sensitivity and/or density of inhibitory alpha$_2$ adrenoceptors (Vetulani, 1984).

It is possible that other antidepressants including novel "atypical" drugs modulate the

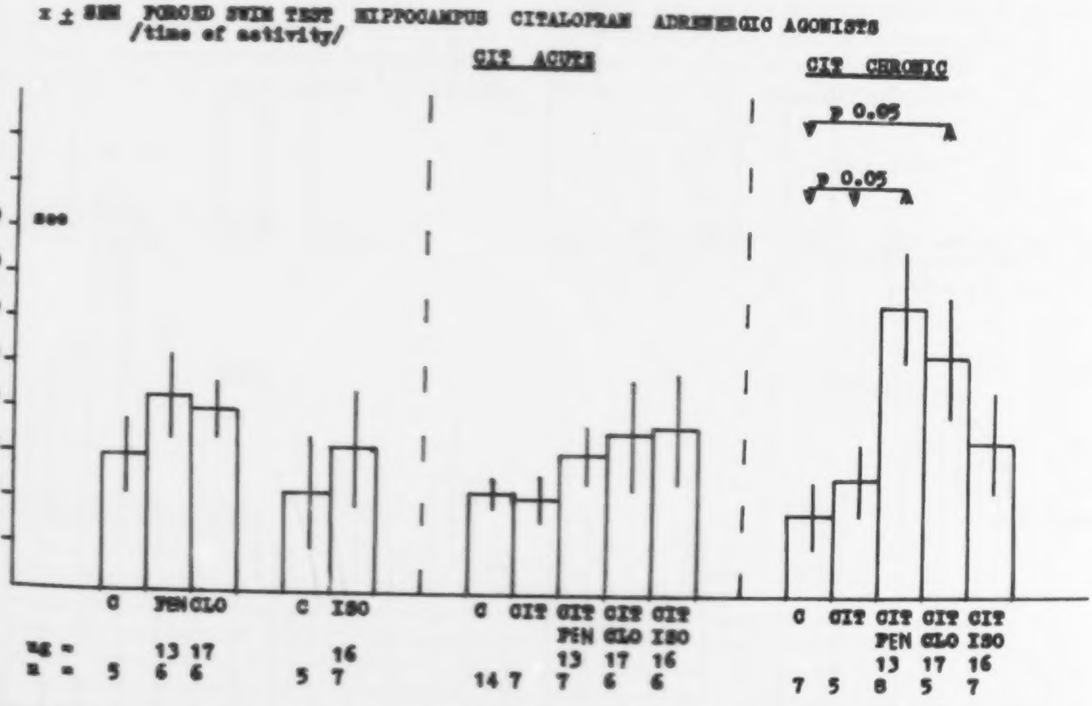

FIGURE 5. Effects of noradrenergic agonists— fenylephrine (FEN, 13 μg), clonidine (CLO, 17 μg) and isoprenaline (ISO, 16 μg) (the doses equimolar to 20 μg of NE, pure substance) injected bilaterally into the dorsal hippocampus—on rats' behavior in the behavioral despair (forced swim) test after acute and chronic pretreatment with DMI. Mean values SEM (*N* = number of rats, C = control). Acute DMI treatment consisted of two daily doses of 10 mg kg^{-1} i.p., the animals were tested 24 hrs after the second dose. Chronic treatment consisted of 21 doses of DMI (10 mg kg^{-1} i.p. once a day), the rats were tested 24 hrs after the last dose, 10 min after intrahippocampal injection of saline. Note that FEN and CLO (but not ISO) produce significant activation in rats treated chronically with DMI (time of activity of animals in vertical scale).

behavioral responses associated with hippocampal alpha adrenoceptors. Most recently the investigators found that citalopram, an atypical drug acting selectively upon serotonin uptake mechanism (Hyttel, 1982) like DMI changed the effects of intrahippocampal phenylephrine and clonidine but failed to potentiate the NE and isoprenaline action. The effect of citalopram occurred, moreover, only in behavioral despair but not the open field (Plaźnik & Kostowski, in press) (Figure 6).

Possible Involvement of Other Limbic Structures

It is likely that limbic structures other than the hippocampus also play a role in the action of antidepressants. Preliminary data indicate that microinjections of NE into the nucleus accumbens produce similarly to intrahippocampal injections, stimulation of rats' behavior in both open field and forced swim test; the latter effect, however, does occur earlier (5 min) than the former (15 min after microinjection) (Plaźnik & Kostowski, in press). Other adrenergic agonists such as phenylephrine, clonidine, and isoprenaline slightly activated the animals' behavior in the forced swim in control (untreated) rats, while in the animals pretreated with multiple doses of DMI both phenylephrine and clonidine (though not isoprenaline) produced strong stimulatory effect. More recent data indicate that dopamine injected into the nucleus accumbens activates the animals' behavior in the forced swim situation, the effect being potentiated following multiple doses of DMI (A. Plaźnik, personal communication). Thus, these preliminary results suggest that NE and possibly also dopaminergic transmission within the nucleus accumbens play a role in the action of DMI.

Conclusion

The results presented here indicate that noradrenergic neurotransmission associated with the LC-hippocampal system (and proba-

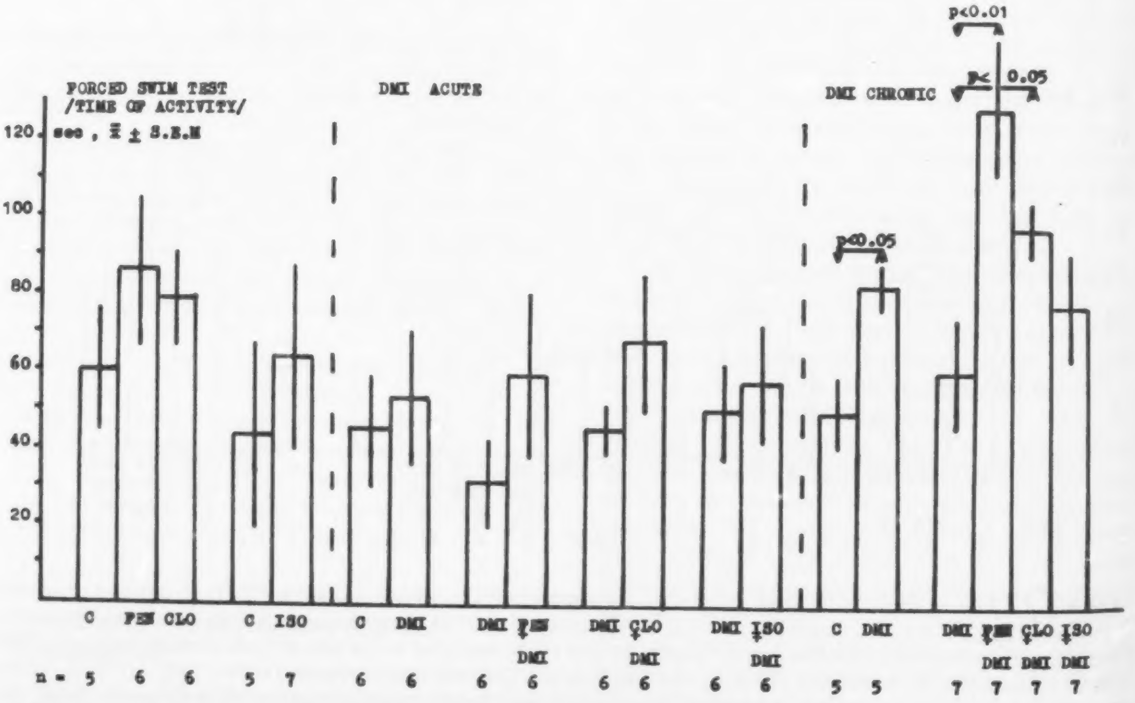

FIGURE 6. Effects of noradrenergic agonists injected intrahippocampally on rats' behavior in the forced swim test after acute and chronic pretreatment with citalopram (the dosage similar to that of DMI: *see* Figure 5 for details). Note that FEN and CLO produce significant activation in rats treated chronically with citalopram (CIT).

bly the other limbic structures) is critically involved in the mode of action of DMI and apparently at least some other antidepressants. The functional consequences of reduction of behavioral responses mediated through alpha$_2$ adrenoceptors are illustrated by the results of the experiments with clonidine. Clonidine inhibits locomotion and exploratory behavior in rats, mice, and other laboratory animals (Delini-Stula et al., 1979; Lal & Shearman, 1981) and produces other symptoms of behavioral depression. The investigators focused recently upon the clonidine effect on dominance behavior in rats competing for food or water (Malatyńska & Kostowski, in press). Clonidine when injected to the dominant rat reduces the dominance and reverses the hierarchy order in the pair of rats (the dominant animal becames submissive). Repetitive doses of tricyclic antidepressants as well as novel "atypical" drugs such as iprindol, mianserine, and salbutamol antagonize clonidine-induced suppression of dominance (Figure 7). This phenomenon seems to be particularly characteristic and selective for antidepressants thus providing the promising possibility to study this group. The finding may reflect also some "psychological" aspects of modulation of alpha$_2$ receptor system in the brain. It is likely that alterations in NE neurotransmission (and perhaps in other transmitter systems) which take place within

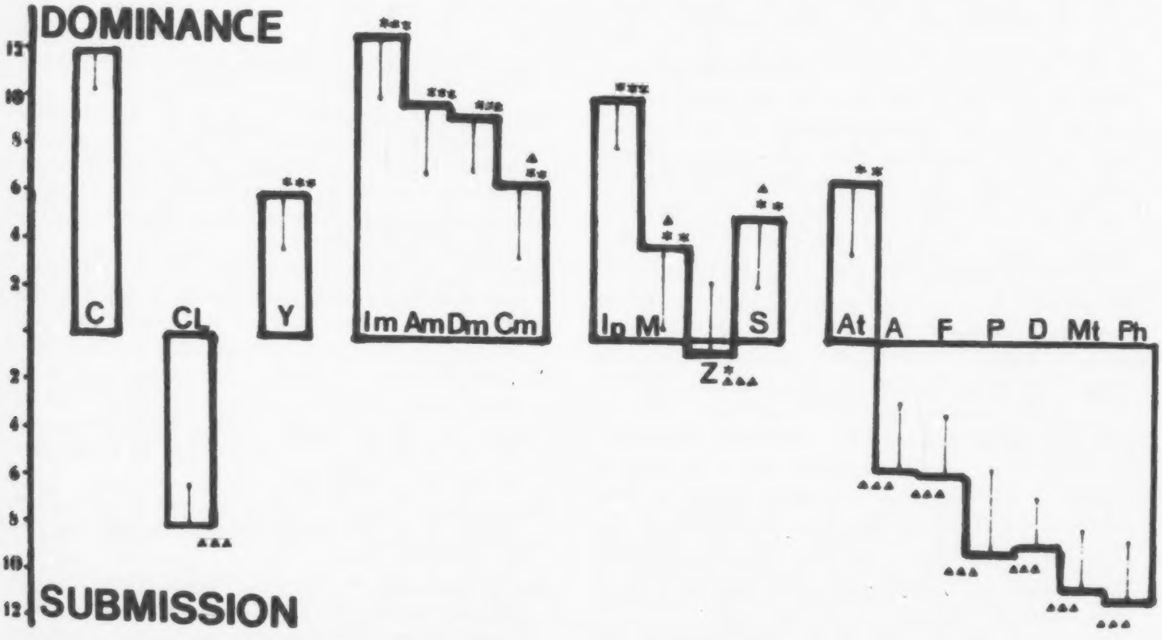

FIGURE 7. Effects of drugs belonging to different groups on dominance behavior in rats competing for food (sweetened milk). Vertical scale: score of dominance expressed as a difference in drinking time between dominant and submissive animals (each 5 sec of drinking was calculated as 1 point). Mean values SEM from 10 to 14 pairs of rats. C = control (saline), CL = clonidine (0.1 mg kg^{-1} i.p.). Drugs were injected once a day in 5 consecutive doses 1 hr before clonidine to the dominant rat (CL group received saline). The test was performed 1 hr after 5th dose of drug-clonidine (or saline-clonidine) combination. Drugs given in combination with clonidine: Y = yohimbine (2.5 mg kg^{-1}), Im = imipramine (2.5 mg kg^{-1}), Am = amitryptiline (2.5 mg kg^{-1}), Dm = desipramine (2.5 mg kg^{-1}), Cm = clomipramine (2.5 mg kg^{-1}), Ip = iprindol (5.0 mg kg^{-1}), M = mianserine (5.0 mgkg^{-1}), Z = zimelidine (5.0 mg kg^{-1}), S = salbutamol (2.0 mg kg^{-1}), At = atropine (1.0 mg kg^{-1}), A = amphetamine (1.0 mg kg^{-1}), F = flupentixol (2 mg kg^{-1} on the 1st day and 1 mg kg^{-1} on the 3rd day), P = pimozide (0.25 mg kg^{-1}), D = diazepam (1.0 mg kg^{-1}), Mt = metergoline (2.0 mg kg^{-1}), and Ph = antazoline (2.5 mg kg^{-1}. ▲ = $p < 0.05$, ▲▲▲ = $p<0.01$ in respect to control (C), x = $p<0.05$, xx = $p<0.02$, xxx = $p<0.01$ in respect to clonidine (CL) group (Student's "*t*" test). Note that only antidepressants (belonging to different groups) and atropine were able to reverse depressive action of clonidine upon the dominance.

the limbic structures and the LC system in the course of chronic antidepressive therapy lead to profound behavioral and psychological effects which are of importance to the mechanism of action of antidepressant drugs.

Summing up, it may be suggested that NE transmission associated with LC- limbic structures is involved in the action of antidepressants. The anatomical and functional integrity of the LC is important for the expression of at least some of the behavioral effects of DMI and AMI. It also seems likely that behavioral phenomena which might be of significance for antidepressive action (e.g., activation of animals' behavior in the behavioral despair situation) are mediated through the alpha$_1$ adrenoceptors rather than beta receptors. Furthermore, the hippocampal alpha adrenoceptors seem to be of particular importance in mediating "antidepressive" behavioral phenomena induced by chronic administration of antidepressants. It was intriguing to establish that the hippocampal (and probably nucleus accumbens) beta adrenoceptors did not participate in the modulation of rats' behavior following long-term DMI and citalopram. The role of beta adrenoceptors in behavioral processes is poorly known, and some authors tend to stress the beta receptor involvement in the control of trophic-metabolic function (Vetulani, 1984).

In conclusion, antidepressants produce characteristic changes in LC-limbic transmission resulting in the facilitation of excitatory signals (e.g., mediated through alpha$_1$ receptors), and in the attenuation of inhibitory signals (e.g., alpha$_2$ receptors). It seems likely that other excitatory signals (e.g., associated with dopaminergic receptors within the nucleus accumbens) could be potentiated following the chronic antidepressants. Further experiments are obviously needed to elucidate this problem.

The "common mechanism" of action of antidepressants should, therefore, be discussed in more functional and anatomical categories. In other words, no conclusion can be drawn from various receptor and metabolic changes until these phenomena are correlated with the function of particular brain structures.

Introduction and Summary: Psychobiological Markers for Schizophrenia: State of the Art and Future Perspectives[1,2]

Joseph Zubin, Ph.D.[3]

Introduction

The purpose of the panel on psychobiological markers for schizophrenia was to update the state of the art since 1977 when the last report was presented to the American College of Neuropsychopharmacology (Zubin, 1979).

During the past 7 years, several developments have taken place which will affect future markers studies. As far as the etiological models which underlie the markers are concerned, the old neuropathological model has been revived in the wake of the new methodologies for brain scanning. The neurophysiological model has been extended to include more neurohumoral and endocrinological factors and immunological system factors, indicating the revival of what used to be called the psychosomatic model (Ader, 1981). In genetics, molecular genetics and mapping (HLA) have developed very rapidly. Some of these advances in etiological models are providing new potential markers for schizophrenia.

Perhaps one of the most striking developments during the past septennial was the provision of systematic structured and semistructured interviews for diagnosis, resulting in a high degree of reliability in the classification of the mentally ill. As a consequence, it became possible to provide research diagnostic criteria based on these interviews and a new codification of the Diagnostic and Statistical Manual—DSM-III (American Psychiatric Association, 1980) that laid a firmer foundation for specificity in the search for markers. There has also developed a stronger interest in fractionating schizophrenia and also depression into subcategories. In schizophrenia, the use of positive and negative symptoms and their relation to drug effects has provided some tentative new classifications of subgroups which may provide new markers. The positive symptoms seem to characterize patients during their episode, since the symptoms often wax and wane with the episode. The negative symptoms are alleged to be more persistent but there seems to be some doubt whether they are indigenous parts of schizophrenia (Zubin, 1985). Despite these efforts at subcategorization of schizophrenia, there has been a revival of the unitary hypothesis of the functional disorders (Bleuler, 1972; Meltzer, 1984) so that we may find the same markers identifying both the schizophrenias as well as the affective disorders. Another new development has arisen from the results of the long-term follow-up studies of schizophrenia (Bleuler, 1972; Ciompi, 1980; Harding & Strauss, in press; Huber et al., 1980), which seem to cast doubt on the malignant chronic character that has been attributed to schizophrenia, changing it to a more benign disorder. The vulnerability model also points to a change in that direction, substituting a vulnerability to schizophrenia for the belief that it is a persistent deteriorating process. This vulnerability may or may not lead to episodes, but the episodes, according to the vulnerability model, are intermittent, leading eventually to a good outcome in the majority of patients (Bleuler, 1972; Ciompi, 1980; Harding & Strauss, in press; Huber et al., 1980). Thus, episode markers may assume greater importance because they can help in determining beginnings and ends of episodes.

One methodological innovation during the past 7 years was the introduction of information processing procedures in the quest for markers (Kietzman et al., 1984). Since one of the behavioral deviations in schizophrenia is in the domain of information reception and transmission, especially in the cognitive domain, it is clear why information processing is so important in the search for markers. In

earlier days, the mere finding of a difference between schizophrenic and non-schizophrenic patients and normals was regarded as a remarkable achievement in itself. Today, such a finding is only the beginning. It becomes necessary to find just where the deviation occurs in the processing of the information under examination, in which time period and how it relates to the preceding and succeeding processing procedures. Furthermore, the vast knowledge of information processing that has accumulated in the last few decades in normal functioning lays the foundation for detecting deviation in abnormal functioning and thus provides a solid framework for the search for markers. Instead of depending upon serendipity alone, a systematic search can be launched.

The role of information processing in providing a systematic framework for the search for markers is most strikingly illustrated in studies of attention. It is perhaps the most popular area for schizophrenia research. On the one hand, in order to be able to carry out any experimental task, the schizophrenic must apply attention; but, on the other hand, we hypothesize with Kraepelin and many others that attention is somehow deviant in schizophrenics. How can we trust the outcome of an experiment to reflect performance of the task itself when deviations in attention rather than in the functions under investigation may explain the deviant performance? The results of many experiments in psychopathology have run afoul of the general deficit syndrome. The performance of patients (slowness or less accuracy) may be poor simply because they are not motivated, do not understand the instructions, or cannot attend to the task requirements.

Our first attempt to deal with this problem was to ignore it by designing tasks in which deviation in attention could probably not affect the results. We chose tasks that resulted in responses occurring within the first 1,000 msec following stimulation. In such tasks, attention could play either no role or a minor role because they did not depend upon the engagement of awareness and cognitions of a high order, reducing the role of attention to a minimum. To attain this end we developed the cross-modality reaction-time task (Sutton et al., 1961). This task consists of responding with the same simple finger lift as each stimulus appears and the reaction time of the cross-modal stimuli was compared with ipsimodal stimuli where any deviation in attention, if it did occur, could cancel out.

Another strategy was to devise tasks in which schizophrenics excelled normals, so that the general deficit syndrome could not be used to explain the results. An example of this type of strategy is the recent perceptual organization research devised by Place and Gilmore (1980) in which schizophrenic patients perform more rapidly than normal controls under some conditions. This better performance is attributable to the fact that the control subjects' perception seems to be influenced by the organizational complexities of the visual stimuli and they, therefore, take longer to count the stimuli while the schizophrenics blithely ignore these organizational complexities and finish the counting task more quickly.

Another answer to this question was the statistically controlled design due to the Chapmans (1973), which, by the way, was successfully applied to the cross-modality technique by Manuzza et al. (1984). They demonstrated that our initial assumption that attention played no differential role for normals in the cross-modality reaction-time task was verified. The distribution of ipsimodal and cross-modal functions were found to be psychometrically equivalent in normals, requiring no equating. It is ironic that our attempt to ignore attention, though successful in normals, revealed the deviation that schizophrenics display in shifting attention.

In the dichotic listening studies of Dr. Spring (1985), the various tasks in her experiments were also equated on the normal control group, thus eliminating the possibility of the general deficit syndrome as an explanation of her findings.

Finally, a frontal attack on attention itself was made in such techniques as the Continuous Performance Task (CPT) and Span of Apprehension. Although it is quite clear that these techniques reveal differences between schizophrenics, their unaffected first-degree relatives, and contrasted normal controls, to my knowledge the Chapman argument and the general deficit factor were never addressed in these techniques. Similarly, I do not know whether attention and the general deficit syndrome play a role in the smooth pursuit eye movement task. The fact that Shagass et al. (1976) showed that forcing attention to the numerals on the swinging pendulum reduces the phenomenon, makes one wonder whether attention may not be a factor.* Not all of these measures of attention have been shown to be vulnerability markers and some may turn out to be episode or residual markers.

In the psychosocial sphere, social networks, family deviance and emotional expression in families with highly critical members, as contrasted with nurturing accepting members, have developed prominently as factors in vulnerability, especially in the study of relapses. Whether they can serve as vulnerability markers or episode markers remains to be seen.

The question of whether markers may now serve as the independent variable for classifying mental disorders has arisen. A more equitable approach is the iterative method where either the marker or the diagnostic category can serve alternatingly as the initial entry point. Then the independent variable can change places with the dependent variable, the latter becoming the independent variable and a new analysis made of the data. In this way, both the marker and the diagnostic categories can be further refined.

In line with the need for a "trigger" to trip an episode in the vulnerable, the rapid developments in the field of immunological studies have indicated that stressors seem to lead to a breakdown in the immune system and hence this system could be used to detect triggering stressful events and thus serve to mark the beginnings and ends of episodes (Ader, 1981).

As far as episode markers are concerned, the work on chemical as well as behavioral challenges may show the way for determining the beginnings and ends of episodes (van Kammen, 1985).

As for residual markers, only a comparison of patients who do not show residual markers with those that do can throw light on the indigenous character of residual markers or defects.

Future Perspectives

As for the future, there seems to be a greater tendency to accept the concept of non-familial schizophrenia or phenocopies to use the genetic term. Some of the positive evidence for non-genetic etiology of schizophrenia are the role of perinatal factors, ophthalmological, and other congenital deviations (Zubin, 1979) and the potential of persistent long-term stress for inducing a schizophrenic episode (Dohrenwend & Dohrenwend, 1981). On the negative side, it seems that the role of penetrance in studies of sporadic schizophrenics has not been fully appreciated. For the monogenic hypothesis, the degree of penetrance is on the order of .25. If this is accepted, it can readily be shown that a minimum of 20 first-degree relatives for a single proband is necessary before dismissing the role of genetics on the .95 level of confidence. Since very few probands would have as many as 20 first-degree relatives, it becomes necessary to examine for each proband separately by means of a 4-fold table comparing the number of affected and unaffected first-degree relatives with chance expectancy and the value of chi square computed for each of these 4-fold tables. The distribution of these chi square values should not differ from its expected chance distribution if we are to conclude that probands suffer from a nonfamilial disorder. How to determine the minimum number of first-degree relatives for multiple families and for polygenic hypotheses needs to be worked out. If a threshold value for determining the dichotomy into vulnerable-invulnerable individuals can be developed, the polygenic model can also be dealt with in a manner analogous to the monogenic model and the minimal number of first-degree relatives determined in like manner.

In considering the variety of possible markers (Zubin, 1985) it can be shown that in addition to vulnerability markers there are at least two types of invulnerability markers. Thus, a marker which is present premorbidly, morbidly, and postmorbidly but occurs in unaffected first-degree relatives with no greater frequency than chance expectancy, can be regarded as an invulnerability marker since its absence seems to protect the first-degree relatives from developing an episode. By the same token, if a marker occurs in the unaffected first-degree relatives with a frequency exceeding chance, but does not occur in the probands, it could be interpreted as an invulnerability marker, since its presence in the first-degree relatives probably protects them against developing an episode, and its absence in the proband permitted the development of an episode.

---

*Philip Holzman has addressed this question in his Dean Award Lecture, in press.

At this point one may raise the question of what is meant by a genetic disorder. Since, in the last analysis, the human organism can react only in ways permitted by its genome, every disorder must be genetically compatible with the genome of the organism. What then is meant by a genetic disorder? Woodworth (1941) long ago pointed out that the relative proportion of the variance of a trait attributable to hereditary or environmental factors is what determines our decision as to whether the trait is hereditary or environmental in origin. Thus, if all the members of the group under study have identical genomes, any variation in a trait must be due to environment and mutatis mutandis for identical environments. But even such disorders as phenylketonuria (PKU) or Tay Sachs disease may be genetic disorders only in our social-cultural physical environment. Perhaps we call a disorder genetic when we have some evidence for genetic transmission but are ignorant of the required environmental assists. Similarly, we may call a disorder environmental when we know the noxious environmental agents but have not yet discovered the genetic factors.

Finally, the increase in interest in psychosocial aspects of vulnerability, though it may not contribute to etiology (although some theorists claim that it does) (Dohrenwend & Dohrenwend, 1981), certainly contributes to the triggering, maintenance, and recurrence of episodes It becomes necessary to determine the link between external factors producing stress with the internal responses to stress in the immunological, endocrinological systems in their interaction with the central nervous system. The study of the psychosocial factors may lead to a better understanding of chronicity and recidivism, and may point to the entry path for intervention.

It is also important to determine whether the markers are associated with the disorder (pathophysiological markers) or have no direct association with the disorder (linkage type). The former may be prodromal in character in so far as they may develop only after the incipient onset of the disorder and hence may serve more as episode markers than vulnerability markers, although some markers may serve both as episode and vulnerability markers, e.g., P300. The linkage type markers may occur coincidentally with schizophrenia rather than causally, e.g., are located on the same chromosomes close to the alleles determining schizophrenia, and hence can be depended upon to distinguish unaffected first-degree relatives. Pathophysiological markers that occur in unaffected first-degree relatives strengthen the possibility that they are at least in part vulnerability rather than episode markers.

It should also be borne in mind that not all individuals will develop an episode even if they possess the marker identifying them as vulnerable and are subjected to sufficiently noxious stressors. Certain moderating variables such as social networks, ecological niches, and premorbid personality may absorb the stress and prevent the episode if they are favorable, or enhance the probability of a developing episode if they are unfavorable (Zubin et al., 1985).

Finally, the response to treatment may itself serve as a marker, differentiating those who benefit from those who do not.

Summary of Panel Presentations

Some of the outstanding contributions of the present panel summarizing the state of the art as of 1985 are as follows:

Generally, markers of vulnerability can be found not only in the genetic domain but also in any of the other seven domains of the etiological models of schizophrenia (Zubin et al., 1981). One model, the neurophysiological model, seems to possess certain transcending characteristics which need to be pointed out. Since neurophysiology underlies all behavior, deviations in this carrier wave for behavior should accompany any of the disordered behavior by which we now recognize the presence of schizophrenia. As an example, P300 transcends the characteristics of the stimulus which elicits it, appearing independently of the modality in which it arises and of some of the other properties of the stimulus which elicit it. Hence, it becomes an independent indicator of brain function, independent of its origin, and is an endogenous brain response to stimulation. Consequently, P300 and other components of the event-related potentials are excellent measures of the deviations in information processing which may characterize schizophrenia. In contrast with other techniques which can not always transcend the concrete matrix from which they emanate, physiological indicators may be free of them. It may serve the same purpose in analyzing brain function that factor analysis serves in analyzing the common elements in many performances. Another virtue of physiological indicators is that they can be repeated as often as required (within limits of adaptation). Consequently, the final averaged result is relatively free of noise.

One finding reported by Steinhauer (1985) is that the pattern of response of P300 to the various degrees of uncertainty of the stimulus is quite different in schizophrenics than in normals. This additional possibility of determining a pattern over several degrees of uncertainty makes the analysis more flexible, so that individuals can be clustered in accordance with the pattern they exhibit. Since the likelihood of finding pathognomonic markers is rather low, the pattern across different markers may also help to group individuals into like-minded clusters. Thus, instead of being merely a group phenomenon, the marker or markers can pin-point the single individual and his peers and, therefore, can be used meaningfully in dealing with them.

An interesting example of how the different characteristics of a disorder vary in the degree of their pathognomicity is found in PKU. Taking the marker of the concentration of phenylalanine in the blood plasma, the distribution for normals is from 0 to about 2%, while the distribution for PKU patients is from about 15% to 40%, with no overlap. However, if IQ is taken as a marker, the distribution for PKU overlaps with the distribution for normals between IQs of 20 and 125. Similarly, in the distribution for head size PKU overlaps with that of normals between 300 and 350 mm. For hair color reflectance, the PKU distribution overlaps with the normal distribution almost completely—from 0 to 30%. However, it is possible that if the pattern of IQ status, head size, and hair color reflectance were obtained for PKU for each patient and for each normal, the overlap between the patterns would be reduced considerably. Our markers for schizophrenia resemble more the hair color reflectance measure than the phenylalanine concentration in blood plasma, and that is why we need to be satisfied with patterns of markers rather than search for pathognomonic markers (Levitan & Montagu, 1977).

At present, the beginnings and terminations of episodes are based purely on clinical observations and hunches. Dr. van Kammen (1985) has pointed out that it may be possible to develop objective episode markers which would enable us to recognize the imminence of an incipient episode or the imminence of its termination. The ability to perceive the approaching episode may help in the selection of suitable intervention strategies, while knowledge that the episode is terminating may be of value in altering the treatment regimen. The question raised by Dr. van Kammen is whether we can find suitable biochemical challenges to serve as episode markers. If this can be done, they could serve as indicators for the beginning and end of treatment. We may possibly be able to abort incipient episodes or prevent needless continuation of drug treatment with its dangers of inducing tardive dyskinesia. Among the candidates for episode markers are (1) growth hormone responses to apomorphine, (2) psychotogenic response to amphetamine and methylphenidate, and (3) relative cerebrospinal fluid/norepinephrine levels (van Kammen, 1985).

These challenges can serve as chemical stressors, even as high emotional expression in families serve as environmental stressors. The controlled graduated stress which can be induced by amphetamine may serve to trigger a miniepisode in those who are still in their episode, while this chemical challenge may produce little or no effect in those in whom the episode is ended. It is likely that behaviorally induced stressors may serve the same purpose (Zubin & Steinhauer, 1981).

In the cognitive domain, Dr. Spring (1985) has added a new marker of vulnerability—intrusions in dichotic listening with distractors, especially in delusional schizophrenics. The performance of these schizophrenics on the shadowing task itself is not impaired but, unlike their controls, they make intrusions from the non-target ear in their shadowing. This holds true not only of the schizophrenic probands but also of their first-degree relatives, and does not seem to disappear in remitted cases. It also does not characterize nonparanoid schizophrenics and nonschizophrenic mental patients and their relatives. Dr. Spring suggests that the deviation in information processing which this marker presents may be due to a difference in the allocation of attention capacity. The schizophrenic may be allocating more processing capacity to performance on this task than normals, without interfering with accuracy of shadowing on the main channel. According to this suggestion, schizophrenics may be excelling in their performance since, despite instructions to monitor only the main channel, they succeed in monitoring even the forbidden channel to some extent.

In the perceptual domain, Dr. Kietzman (1985) has pointed out that the speed of visual information processing is characteristically slowed down in schizophrenics. Two techniques for measuring the speed of processing are now available: span of apprehension and backward masking. Dr. Knight has suggested that the slowed processing may be a long-term characteristic product of a perceptual organization deficiency in schizophrenics with poor premorbid personalities (Knight, 1984).

All in all, the last 7 years have been a period of consolidation and gradual rather than rapid further development. In a sense it was the sabbatical year for markers; nevertheless, the impact of information processing as a framework has been strongly felt. Several of the markers have entrenched themselves more firmly by providing evidence of their existence in unaffected first-degree relatives—a requirement for establishing them as vulnerability markers.

In the 1977 report (Zubin, 1979) the following potential vulnerability markers (as determined by presence in unaffected first-degree relatives) were reported: (1) Cancro's measures of blinking during visual mental tasks, (2) Holzman's smooth pursuit eye movements, (3) Cromwell's cross-over index in reaction time, and (4) Rosvold's and Orzack's vigilance task of continuous performance.

Today, the list of potential vulnerability markers is as follows: cross-over reaction time, span of apprehension, CPT, backward masking, smooth pursuit eye movements and dichotic listening with distraction. Those awaiting vulnerability status are: cross-modality reaction time, evoked potentials, pupillographic responses, and heart rate.

Very little progress has been made in the area of residual markers, an area which is in need of further development, though it has been suggested that some negative symptoms may qualify as residual markers. The other types of markers and their usefulness are waiting for further research.

Psychopharmacology—A Recurring Bibliography—

The bibliography below is offered to our readers to alert them to recent papers on psychopharmacology from the world literature. It was computer-generated by the Medical Literature Analysis and Retrieval System (MEDLARS) of the National Library of Medicine, National Institutes of Health, and represents papers which were entered into the system during the 3 months before this issue of the *Bulletin* went to press.

The subject headings from Index Medicus were selected at the NIMH to reflect significant current interest of the international scientific community. Some nonrelevant citations may appear, and some relevant ones may be absent, but this is usual for machine-generated searches.

Animal models of behavioral pathology and violent aggression. Valzelli L. **Methods Find Exp Clin Pharmacol** 1985 Apr;7(4):189-93

The effect of milenperone on the aggressive behavior of psychogeriatric patients. A double-blind placebo-controlled study. De Cuyper H, et al. **Neuropsychobiology** 1985;13(1-2):1-6

The role of central noradrenergic neurons in electroconvulsive shock-induced muricide inhibition in olfactory bulbectomized rats. Liou SY, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):65-70

Benzodiazepine-receptor mediated inhibition of isolation-induced aggression in mice. Skolnick P, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):17-20

Evidence of norepinephrine-mediated suppression of para-chlorophenylalanine-induced muricidal behavior. Pucilowski O, et al. **Pharmacol Res Commun** 1985 May;17(5):457-62

Human aggression and the role of central serotonin. Mühlbauer HD. **Pharmacopsychiatry** 1985 Mar;18(2):218-21

The cholinergic influences on aggression in isolated mice. Herbut M, et al. **Pol J Pharmacol Pharm** 1985 Jan-Feb;37(1):1-10

Maternal aggression in rats: effects of chlordiazepoxide and fluprazine. Olivier B, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):68-76

[Change in certain forms of aggressive behavior and the concentration of monoamines in the brain during selection of wild rats for taming] Nikulina EM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):703-9 (Eng. Abstr.) **(Rus)**

[Discrete and continuous mathematical models of intraspecific behavior in the pharmacoethology of the mouse] Poshivalov VP, et al. **Zh Vyssh Nerv Deiat** 1985 May-Jun;35(3):487-96 (Eng. Abstr.) **(Rus)**

AMINO ACIDS

Moroamine, amino acid and cholinergic interactions in slices of rat cerebral cortex. Flint RS, et al. **Brain Res Bull** 1935 Aug; 15(2):197-202

Effectors of amino acid transport processes in animal cell membranes. Lerner J. **Comp Biochem Physiol** [A] 1985;81(4):713-39 (194 ref.)

Characteristics and hormonal regulation of amino acid transport system A in isolated rat hepatocytes. Kilberg MS, et al. **Curr Top Cell Regul** 1985;25:133-63 (79 ref.)

Interplay of nutrients and hormones in the regulation of insulin release. Pipeleers DG, et al. **Endocrinology** 1985 Sep;117(3):824-33

Interplay of nutrients and hormones in the regulation of glucagon release. Pipeleers DG, et al. **Endocrinology** 1985 Sep;117(3):817-23

Relationship of brain glutamine and brain neutral amino acid concentrations after portacaval anastomosis in rats. Jeppsson B, et al. **Eur J Clin Invest** 1985 Aug;15(4):179–87

Differential effects of dextrorphan and levorphanol on the excitation of rat spinal neurons by amino acids. Church J, et al. **Eur J Pharmacol** 1985 May 8;111(2):185–90

Blocking action of pentobarbital on receptors for excitatory amino acids in the guinea pig hippocampus. Sawada S, et al. **Exp Brain Res** 1985; 59(2):226–31

Reversed-phase high-performance liquid chromatographic separation and quantitation of phenylthiohydantoin derivatives of 25 amino acids, including those of cysteic acid, 4-hydroxyproline, methionine sulfone, S-carboxymethylcysteine and S-methylcysteine. Kolbe HV, et al. **J Chromatogr** 1985 Jun 26;327:1–7

Determination of amino acids by separation of their ion pairs with dodecyl sulphate. Seiler N, et al. **J Chromatogr** 1985 May 31;341(1):11–21

1-Piperideine as an in vivo precursor of the gamma-aminobutyric acid homologue 5-aminopentanoic acid. Callery PS, et al. **J Neurochem** 1985 Sep;45(3):946–8

Excitatory effect of amino acids on identified neuron R14 of Aplysia. II. Neutral amino acids and structure-activity relationships. Ichinose M, et al. **J Neurosci Res** 1985;14(1):145–58

Potassium movements associated with amino acid and sugar transport in enterocytes isolated from rabbit jejunum. Brown PD, et al. **J Physiol (Lond)** 1985 Jun;363:271–85

Effect of excitatory amino acids on gamma-aminobutyric acid release from frog horizontal cells. Cunningham JR, et al. **J Physiol (Lond)** 1985 May;362:51–67

Amino acids release somatostatin-like immunoreactivity from isolated rat glomeruli. Fujibayashi S, et al. **Mol Cell Endocrinol** 1985 Jul; 41(2-3):263–7

Stability of the amino acid content of nerve endings after administration of gamma-aminobutyrate agonists and antagonists. Wood JD, et al. **Neuropharmacology** 1985 Jul;24(7):685–7

Dopaminergic toxicity after the stereotaxic administration of the 1-methyl-4-phenylpyridinium ion (MPP+) to rats. Heikkila RE, et al. **Neurosci Lett** 1985 Aug 16;59(1):135–40

Effect of ketamine on amino acid-evoked release of acetylcholine from rat cerebral cortex in vitro. Lodge D, et al. **Neurosci Lett** 1985 May 23;56(3):371–5

Antagonistic effect of delta-aminovaleric acid on bicuculline-insensitive gamma-aminobutyric acid B (GABA B) sites in the rat's brain. Nakahiro M, et al. **Neurosci Lett** 1985 Jun 24;57(3):263–6

Correlation between cytochrome oxidase staining and the uptake and laminar distribution of tritiated aspartate, glutamate, gamma-aminobutyrate and glycine in the striate cortex of the squirrel monkey. Carroll EW, et al. **Neuroscience** 1985 Aug;15(4):959–76

Antramine (antral histamine) antagonizes somatostatin inhibition on endogenous gastrin-induced gastric secretion. A new hypothesis for the role of histamine in gastric secretion regulation. Vatier J, et al. **Scand J Gastroenterol** 1985 Aug;20(6):671–6

[Course of the concentration of serum free amino acids as a function of time and the method of preservation] Hainque B, et al. **Ann Biol Clin (Paris)** 1985;43(3):221–6 (Eng. Abstr.) **(Fre)**

[Conformation study, using an empirical atom-atom potential, of biologically active amino acids as neurotransmitters] Jáuregui EA, et al. **Acta Cient Venez** 1984;35(5-6):337–41 (Eng. Abstr.) **(Spa)**

AMITRIPTYLINE

A placebo controlled comparison of the effects of pirenzepine and amitriptyline on the tyramine pressor test in healthy volunteers. Wilkins MR, et al. **Br J Clin Pharmacol** 1985 Jun;19(6):829–31

Discrepancies between pharmacokinetic studies of amitriptyline. Schulz P, et al. **Clin Pharmacokinet** 1985 May–Jun;10(3):257–68 (43 ref.)

Long-term amitriptyline in chronic depression. Giller E Jr, et al. **Hillside J Clin Psychiatry** 1985;7(1):16–33

Cerebrospinal fluid levels of amitriptyline, nortriptyline, imipramine and desmethylimipramine. Relationship to plasma levels and treatment outcome. Hanin I, et al. **J Affective Disord** 1985 Jul;9(1):69–78

Determination of citalopram, amitriptyline and clomipramine in plasma by reversed-phase high-performance liquid chromatography. Rop PP, et al. **J Chromatogr** 1985 Feb 27;338(1):171–8

Patterns of attrition for psychosocial and pharmacologic treatments of depression. Last CG, et al. **J Clin Psychiatry** 1985 Sep;46(9):361–6

Repeated treatment with imipramine or amitriptyline increases the locomotor response of rats to (+)-amphetamine given into the nucleus accumbens. Maj J, et al. **J Pharm Pharmacol** 1985 May;37(5):362–4

Electro-acupuncture vs. amitriptyline in the treatment of depressive states. Luo HC, et al. **J Tradit Chin Med** 1985 Mar;5(1):3–8

Antidepressant treatment of children: clinical relapse is unrelated to tricyclic plasma concentrations. Olig RM, et al. **Percept Mot Skills** 1985 Jun;60(3):879–89

Serotonin uptake and imipramine binding in rat platelets after chronic dexamethasone and amitriptyline treatment. Chan MY, et al. **Pharmacol Res Commun** 1985 Jul;17(7):619–32

Amitriptylinoxide: receptor-binding profile compared with other antidepressant drugs. Borbe HO, et al. **Pharmacopsychiatry** 1985 Sep; 18(5):314–9

Single oral dose pharmacokinetics of amitriptylinoxide and amitriptyline in humans. Kuss HJ, et al. **Pharmacopsychiatry** 1985 Jul; 18(4):259–62

Cardiovascular effects of single doses of the antidepressants amitriptyline and lofepramine in healthy subjects. Stern H, et al. **Pharmacopsychiatry** 1985 Jul;18(4):272–7

Cardiovascular effects of amitriptyline in the treatment of elderly depressed patients. Christensen P, et al. **Psychopharmacology (Berlin)** 1985;87(2):212–5

Cianopramine and amitriptyline in the treatment of depressed patients—a placebo-controlled study. Hormazabal L, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):205–8

Evaluation of amitriptyline pharmacokinetics during peritoneal dialysis. Tasset JJ, et al. **Ther Drug Monit** 1985;7(3):255–7

[Measurement of basal plasma levels of 3 anterior pituitary hormones during acute or chronic treatment with tricyclic antidepressants] Goyot C, et al. **Encephale** 1985 Mar–Apr;11(2):45–51 (Eng. Abstr.) **(Fre)**

[Serum levels of amitriptyline and nortriptyline in a case of poisoning (letter)] Fernández de Gatta M, et al. **Med Clin (Barc)** 1985 May 18; 84(19):798–9 **(Spa)**

AMOBARBITAL

Toxicological analysis of amobarbital and glutethimide from bone tissue. Benkö A. **J Forensic Sci** 1985 Jul;30(3):708–14

AMPHETAMINE

Succinic and malic dehydrogenase histochemical activities in cerebral, cerebellar and neostriatum sections incubated in presence of d-amphetamine. Martínez-Murillo R, et al. **Acta Neuropathol (Berl)** 1985;67(1-2):81–5

Amphetamine's effects on terminal excitability of noradrenergic locus coeruleus neurons are impulse-dependent at low but not high doses. Ryan LJ, et al. **Brain Res** 1985 Aug 19;341(1):155–63

Differential biochemical and behavioral effects of single and chronic administration of amphetamine and apomorphine. Bernardi MM, et al. **Gen Pharmacol** 1985;16(4):407–10

Differential alterations in brain sensitivity to amphetamine and pentylenetetrazol in socially deprived mice. Faggin BM, et al. **Gen Pharmacol** 1985;16(3):299–302

Trace amines inhibit the electrically evoked release of [3H]acetylcholine from slices of rat striatum in the presence of pargyline: similarities between beta-phenylethylamine and amphetamine. Baud P, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):220–9

Sensitization to stress: the enduring effects of prior stress on amphetamine-induced rotational behavior. Robinson TE, et al. **Life Sci** 1985 Sep 16;37(11):1039–42

Ten years of experience with 1,000 hyperactive children in a private practice. Eichlseder W. **Pediatrics** 1985 Aug;76(2):176–84

Comparative effects of cathinone and amphetamine on fixed-interval operant responding: a rate-dependency analysis. Goudie AJ. **Pharmacol Biochem Behav** 1985 Sep;23(3):355–65

Asymmetrical effect of unilateral cortical lesions and amphetamine on DRL-20: a time-loss analysis. Kubos KL, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):1001–6

Persistent effects of amphetamine, p-chloroamphetamine, and related compounds on central dopamine and serotonin neurons in rodents. Fuller RW. **Psychopharmacol Bull** 1985;21(3):528–32

Drug preference in normal volunteers: effects of age and time of day. de Wit H, et al. **Psychopharmacology (Berlin)** 1985;87(2):186–93

Evaluation of signal detection theory on the effects of psychotropic drugs on critical flicker-fusion frequency in normal subjects. MacNab MW, et al. **Psychopharmacology (Berlin)** 1985;85(4):431–5

The abolition of the partial reinforcement extinction effect (PREE) by amphetamine. Weiner I, et al. **Psychopharmacology (Berlin)** 1985; 86(3):318–23

AMPHETAMINES

A reevaluation of psychotomimetic amphetamine derivatives in humans. Cassels BK, et al. **J Psychoactive Drugs** 1985 Apr–Jun;17(2):129–30

Persistent effects of amphetamine, p-chloroamphetamine, and related compounds on central dopamine and serotonin neurons in rodents. Fuller RW. **Psychopharmacol Bull** 1985;21(3):528–32

Hallucinogenic amphetamine selectively destroys brain serotonin nerve terminals. Ricaurte G, et al. **Science** 1985 Sep 6;229(4717):986–8

ANGER

Metoprolol for intermittent explosive disorder. Mattes JA. **Am J Psychiatry** 1985 Sep;142(9):1108–9

ANOREXIA NERVOSA

Anorectic behavior, mood, and metabolic and endocrine adaptation to starvation in anorexia nervosa during inpatient treatment. Pahl J, et al. **Biol Psychiatry** 1985 Aug;20(8):874–87

Monoamine oxidase inhibitor therapy for anorexia nervosa and bulimia: a preliminary trial of isocarboxazid. Kennedy SH, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):279–85

The management of bulimia nervosa. Fairburn CG. **J Psychiatr Res** 1985; 19(2–3):465–72

Altered norepinephrine metabolism following long–term weight recovery in patients with anorexia nervosa. Kaye WH, et al. **Psychiatry Res** 1985 Apr;14(4):333–42

Disturbances of norepinephrine metabolism and alpha–2 adrenergic receptor activity in anorexia nervosa: relationship to nutritional state. Kaye WH, et al. **Psychopharmacol Bull** 1985;21(3):419–23

[Low blood values of prolactin in women with psychogenic amenorrhea and anorexia nervosa] Natoli A, et al. **Clin Ter** 1985 Jun 30; 113(6):499–501 (Eng. Abstr.) **(Ita)**

ANTIDEPRESSIVE AGENTS

From clomipramine to mianserin: therapeutic relevance of interactions with serotonin uptake and storage, as studied in the blood platelet model. Lingjaerde O. **Acta Psychiatr Scand [Suppl]** 1985;320:10–9 (18 ref.)

Profiles of antidepressant activity with the Montgomery–Asberg Depression Rating Scale. Montgomery SA, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:38–42

Adrenoreceptor interactions of the enantiomers and metabolites of mianserin: are they responsible for the antidepressant effect? Pinder RM. **Acta Psychiatr Scand [Suppl]** 1985;320:1–9 (29 ref.)

Approach to chronic and treatment–resistant depressions. Akiskal HS. **Adv Biochem Psychopharmacol** 1985;40:159–63

How many, and which patients with affective disorders need long–term maintenance therapy? Angst J, et al. **Adv Biochem Psychopharmacol** 1985;40:169–72

Attenuation by antidepressant drugs of alcohol intake in rats. Daoust M, et al. **Alcohol** 1984 Sep–Oct;1(5):379–83

Alprazolam as an antidepressant [letter] Empson P. **Aust NZ J Psychiatry** 1985 Jun;19(2):197

Differential effect of anionic and cationic drugs on the synaptosome–associated acetylcholinesterase activity of dog brain. Deliconstantinos G, et al. **Biochem J** 1985 Jul 1;229(1):81–6

Guidelines for the pharmacological management of depression. Creelman W, et al. **Conn Med** 1985 Sep;49(9):565–9

Influence of renal failure on the kinetics of zimeldine and norzimelidine. Ferry N, et al. **Eur J Clin Pharmacol** 1985;28(4):453–6

Pharmacokinetics and bioavailability of viqualine, a new antidepressant. Fourtillan JB, et al. **Eur J Drug Metab Pharmacokinet** 1985 Jan–Mar; 10(1):3–10

Chronic antidepressant treatment increases enkephalin levels in n. accumbens and striatum of the rat. De Felipe MC, et al. **Eur J Pharmacol** 1985 May 28;112(1):119–22

Behavioral and eegraphic changes induced by dopaminergic antidepressants in rabbits. Bo P, et al. **Farmaco [Sci]** 1985 Aug; 40(8):608–16

Simultaneous measurement of various antidepressants in the plasma of depressed patients by high performance liquid chromatography. Yufu N, et al. **Folia Psychiatr Neurol Jpn** 1984;38(1):57–64

A video analysis of the non–verbal behaviour of depressed patients before and after treatment. Ulrich G, et al. **J Affective Disord** 1985 Jul; 9(1):63–7

Determination of diclofensine, an antidepressant agent, and its major metabolites in human plasma by high–performance liquid chromatography with fluorometric detection. Strojny N, et al. **J Chromatogr** 1985 Jun 14;341(2):313–31

A proposed clinical approach to chronic and 'resistant' depressions: evaluation and treatment. Akiskal HS. **J Clin Psychiatry** 1985 Oct; 46(10 Pt 2):32–7

The new generation antidepressants: promising innovations or disappointments? Ostrow D. **J Clin Psychiatry** 1985 Oct; 46(10 Pt 2):25–31

Design, synthesis, and pharmacological activities of 2–substituted 4–phenylquinolines as potential antidepressant drugs. Alhaider AA, et al. **J Med Chem** 1985 Oct;28(10):1394–8

Effects of rolipram, a novel antidepressant, on monoamine metabolism in rat brain. Kehr W, et al. **J Neural Transm** 1985;63(1):1–12

Determination of indeloxazine in plasma by liquid chromatography and gas chromatography–mass spectrometry. Kamimura H, et al. **J Pharm Sci** 1985 May;74(5):559–61

Binedaline binding to plasma proteins and red blood cells in humans. Morin D, et al. **J Pharm Sci** 1985 Jul;74(7):727–30

Rapid down regulation of beta adrenergic receptors by combining antidepressant drugs with forced swim: a model of antidepressant–induced neural adaptation. Duncan GE, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):402–8

Upregulation of gamma–aminobutyric acid (GABA) B binding sites in rat frontal cortex: a common action of repeated administration of different classes of antidepressants and electroshock. Lloyd KG, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):191–9

Re–evaluation of antidepressant effect of tetrahydrobiopterin [letter] Fleischhacker WW, et al. **Lancet** 1985 Aug 17;2(8451):387

Synergistic interaction between alpha– and beta–adrenergic receptors in rat brain slices: possible site for antidepressant drug action. Pilc A, et al. **Life Sci** 1985 Sep 30;37(13):1183–94

Clinical use of antidepressant blood levels and the electrocardiogram [editorial] Salzman C. **N Engl J Med** 1985 Aug 22;313(8):512–3

Presynaptic serotonin receptor–mediated response in mice attenuated by antidepressant drugs and electroconvulsive shock. Goodwin GM, et al. **Nature** 1985 Oct 10–16;317(6037):531–3

Behavioral evidence for beta–adrenoceptor subsensitivity after subacute antidepressant/alpha 2–adrenoceptor antagonist treatment. Goldstein JM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun; 329(4):355–8

Pharmacological studies on the serotoninergic and nonserotonin–mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L–tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283–8

Neuronal sensitivity to substance P is increased after repeated treatment with tranylcypromine, carbamazepine or oxaprotaline, but decreased after repeated electroconvulsive shock. Jones RS, et al. **Neuropharmacology** 1985 Jul;24(7):627–33

Increase in levels and ex vivo release of thyrotrophin–releasing hormone (TRH) in specific regions of the CNS of the rat by chronic treatment with antidepressants. Lighton C, et al. **Neuropharmacology** 1985 May; 24(5):401–6

Early visual information processing in depressive patients treated with ORG 2766 (an ACTH 4–9 analogue). d'Elia G, et al. **Neuropsychobiology** 1985;13(1–2):63–8

Suppressant effect of REM sleep deprivation on neophobia in normal rats and in rats with selective DSP–4 induced damage of locus coeruleus neurons. Mogilnicka E, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):93–7

Amitriptylinoxide: receptor–binding profile compared with other antidepressant drugs. Borbe HO, et al. **Pharmacopsychiatry** 1985 Sep; 18(5):314–9

The importance of brain serotonergic receptor mechanisms for the action of antidepressant drugs. Ogren SO, et al. **Pharmacopsychiatry** 1985 Mar; 18(2):209–13

Oxaprotiline in the treatment of endogenous depressed inpatients an early clinical trial. Schmauss M, et al. **Pharmacopsychiatry** 1985 Jul; 18(4):282–5

The central action of carbamazepine as a potential antidepressant drug. Maj J, et al. **Pol J Pharmacol Pharm** 1985 Jan–Feb;37(1):47–56

The GABA hypothesis of depression and antidepressant drug action. Bartholini G, et al. **Psychopharmacol Bull** 1985;21(3):385–8

Serotonergic modulation of cortical rat noradrenergic system in the mechanism of action of antidepressant drugs. Brunello N, et al. **Psychopharmacol Bull** 1985;21(3):379–84

Melancholia in rodents: neurobiology and pharmacology. Henn FA, et al. **Psychopharmacol Bull** 1985;21(3):443–6

Studies of beta–adrenergic receptors in leukocytes of patients with affective illness and effects of antidepressant drugs. Pandey GN, et al. **Psychopharmacol Bull** 1985;21(3):603–9

Panic attacks in outpatients with depression: response to antidepressant treatment. Robinson DS, et al. **Psychopharmacol Bull** 1985; 21(3):562–7

The serotonin/norepinephrine–linked beta–adrenoceptor system and the mode of action of antidepressants. Sanders–Bush E, et al. **Psychopharmacol Bull** 1985;21(3):373–8

Delayed biochemical changes following antidepressant treatment. Sugrue MF. **Psychopharmacol Bull** 1985;21(3):619–22

Ro 11–2465 (cyan–imipramine), citalopram and their N–desmethyl metabolites: effects on the uptake of 5–hydroxytryptamine and noradrenaline in vivo and related pharmacological activities. Pawlowski L, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):156–63

Behavioral screen for antidepressants: the effects of drugs and electroconvulsive shock on performance under a differential–reinforcement–of–low–rate schedule. Seiden LS, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):55–60

Antidepressants and serotonergic neurotransmission: an integrative review. Willner P. **Psychopharmacology (Berlin)** 1985;85(4):387–404 (244 ref.)

Informed consent in psychiatric research: preliminary findings from an ongoing investigation. Benson PR, et al. **Soc Sci Med** 1985; 20(12):1331–41

Experience with a specific request form for antidepressant drug monitoring. Fraser AD. **Ther Drug Monit** 1985;7(3):299–302

[Action of clovoxamine on the sleep of depressed patients. 'Polygraphic recordings'] Minot R, et al. **Encephale** 1985 Mar–Apr;11(2):65–70 (Eng. Abstr.) **(Fre)**

ANXIETY

Separate and combined anxiolytic and anti-depressant treatment of mixed anxiety/depression. A double-blind, placebo controlled comparison. Sussex Clinical Trials Group. **Acta Psychiatr Scand** 1985 Jul; 72(1):81–8

Depression and anxiety: mianserin and nomifensine compared in a double-blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67–74

Chronic anxiolytic treatment: benefit and risk. Marks J. **Adv Biochem Psychopharmacol** 1985;40:173–83

Indications and contraindications for chronic anxiolytic treatment: is there tolerance to the anxiolytic effect? Rickels K, et al. **Adv Biochem Psychopharmacol** 1985;40:193–204

Biological stress responses in high and low trait anxious students. Davis DD, et al. **Biol Psychiatry** 1985 Aug;20(8):843–51

Correlation of [3H]diazepam binding density with anxiolytic locus in the amygdaloid complex of the rat. Thomas SR, et al. **Brain Res** 1985 Sep 2;342(1):85–90

Effect of beta-receptor blockade on anxiety with reference to the three-systems model of phobic behavior. Fagerström KO, et al. **Neuropsychobiology** 1985;13(4):187–93

Studies on the suanzaorentang in the treatment of anxiety. Chen HC, et al. **Psychopharmacology (Berlin)** 1985;85(4):486–7

[Questionnaires for anxiety and depression] Harlay A. **Infirm Fr** 1985 Apr; (264):15–22 **(Fre)**

[Treatment of anxious-depressive syndromes with Mianserin hydrochloride. Statistical evaluation of the data by Student's 't test'] Spinetti G, et al. **Minerva Psichiatr** 1985 Jan–Mar;26(1):79–86 (Eng. Abstr.) **(Ita)**

ANXIETY DISORDERS

Treatment outlines for the management of anxiety states. The Quality Assurance Project. **Aust NZ J Psychiatry** 1985 Jun;19(2):138–51

Topographic EEG changes with benzodiazepine administration in generalized anxiety disorder. Buchsbaum MS, et al. **Biol Psychiatry** 1985 Aug;20(8):832–42

Anxiety: the pharmacological and sociological interface. Proceedings of a symposium. Englefield Green, Surrey, 29 November–1 December, 1984. **Br J Clin Pract [Symp Suppl]** 1985 May;38:1–107

Buspirone: its potential role in the treatment of general practice anxiety. Beaumont G. **Br J Clin Pract [Symp Suppl]** 1985 May;38:100–6

Models of anxiety. File SE. **Br J Clin Pract [Symp Suppl]** 1985 May; 38:15–20

Anxiety, performance and anti-anxiety drugs. Hindmarch I. **Br J Clin Pract [Symp Suppl]** 1985 May;38:53–8

The pharmacological treatment of anxiety. Jenner FA, et al. **Br J Clin Pract [Symp Suppl]** 1985 May;38:48–52

Clinical profile of buspirone. Knapp JE. **Br J Clin Pract [Symp Suppl]** 1985 May;38:95–9

Anxiety disorders: diagnosis and treatment. Jack RA, et al. **Compr Ther** 1985 Jul;11(7):31–7

A multi-centre, double-blind parallel trial of bromazepam ('Lexotan') and lorazepam to compare the acute benefit-risk ratio in the treatment of patients with anxiety. Cordingley GJ, et al. **Curr Med Res Opin** 1985; 9(7):505–10

Thyroid indices in panic disorder. Fishman SM, et al. **J Clin Psychiatry** 1985 Oct;46(10):432–3

Beta-blockers in situational anxiety [editorial] **Lancet** 1985 Jul 27; 2(8448):193

The influence of ritanserin, a serotonin antagonist, in anxiety disorders: a double-blind placebo-controlled study versus lorazepam. Ceulemans DL, et al. **Pharmacopsychiatry** 1985 Sep;18(5):303–5

Initial study of methylclonazepam in generalized anxiety disorder. Evidence for greater power in the cross-over design. Ansseau M, et al. **Psychopharmacology (Berlin)** 1985;87(2):130–5

Metoprolol, a new selective beta-blocker in anxiety neurosis. Chaturvedi SK. **Psychopharmacology (Berlin)** 1985;85(4):488

[Clinical experiences with the new-generation anxiolytic agent cloxazolam—a double-blind study] Zmorski T, et al. **Schweiz Rundsch Med Prax** 1985 Jul 2;74(27):728–34 (Eng. Abstr.) **(Ger)**

APOMORPHINE

Effects of single and repeated application of clonazepam and diazepam combined with cyproheptadine on apomorphine stereotypy in rats. Georgiev VP, et al. **Agressologie** 1985 Jan;26(1):57–60

Apomorphine's antipsychotic activity [letter] Schaffer MH, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):927–8

The effect of dopamine, apomorphine and piribedil on the mesenteric blood flow of the cat. György L, et al. **Arch Int Pharmacodyn Ther** 1985 May;275(1):22–32

Vasomotor responses of cerebral arterioles in situ to putative dopamine receptor agonists. Edvinsson L, et al. **Br J Pharmacol** 1985 Jun; 85(2):403–10

Clonidine sensitizes mice for apomorphine-induced stereotypic gnawing: antagonism by neuroleptics and cholecystokinin-like peptides. Zetler G. **Eur J Pharmacol** 1985 May 20;111(3):309–18

Determination of apomorphine in rat plasma and brain by high-performance liquid chromatography with electrochemical detection. Bianchi G, et al. **J Chromatogr** 1985 Feb 27;338(1):230–5

Effect of ergometrine on methamphetamine and apomorphine stereotypy in the guinea-pig. Balsara JJ, et al. **J Pharm Pharmacol** 1985 Jul; 37(7):514–7

Effects of isomers of apomorphines on dopamine receptors in striatal and limbic tissue of rat brain. Kula NS, et al. **Life Sci** 1985 Sep 16; 37(11):1051–7

Quantification of dopaminergic supersensitization using apomorphine-induced behavior in the mouse. Randall PK. **Life Sci** 1985 Oct 14;37(15):1419–23

S(+)Apomorphines. Selective inhibition of excitatory effects of dopamine injected into the limbic system of the rat. Campbell A, et al. **Neuropharmacology** 1985 May;24(5):391–9

Effects of the contraceptive pill on sedative responses to clonidine and apomorphine in normal women. Chalmers JS, et al. **Psychol Med** 1985 May;15(2):363–7

Lidocaine kindling is accompanied by an increase in apomorphine stereotypy and mesolimbic dopamine D2 receptor density. Csernansky JG, et al. **Psychopharmacol Bull** 1985;21(3):707–11

Dopamine agonist action in mesolimbic, cortical and extrapyramidal areas to modify spontaneous climbing behaviour of the mouse. Costall B, et al. **Psychopharmacology (Berlin)** 1985;86(4):452–7

Yawning elicited by systemic and intrastriatal injection of piribedil and apomorphine in the rat. Dourish CT, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):175–81

Repeated treatment with imipramine potentiates the locomotor effect of apomorphine administered into the hippocampus in rats. Smiałowski A, et al. **Psychopharmacology (Berlin)** 1985;86(4):468–71

REM sleep deprivation effect on apomorphine-induced gnawing is reversed by dexamethasone. Nez L, et al. **Sleep** 1985;8(3):283–7

[Effect of 2 new GABA-ergic agents on apomorphine stereotypy in the rat] Vamvakidès A. **Agressologie** 1985 Jan;26(1):63–5 (Eng. Abstr.) **(Fre)**

[Effect of arachidonic acid on stereotyped behavior in the rabbit induced by a dopamine receptor agonist] Kurchikov AL, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):783–5 **(Rus)**

APPETITE

The effect of captopril on sodium appetite in adrenalectomized and deoxycorticosterone-treated rats. Elfont RM, et al. **J Physiol (Lond)** 1985 Aug;365:1–12

The dependence of the salt appetite of the rat on the hormonal consequences of sodium deficiency. Epstein AN. **J Physiol (Paris)** 1984; 79(6):496–8

AROMATIC AMINO ACID DECARBOXYLASES

1-DOPA decarboxylase and dopamine-beta-hydroxylase isolated from sympathetic splenic nerves estimated by sodium dodecyl sulphate polyacrylamide gel electrophoresis with and without mercaptoethanol. Husseini HS, et al. **J Chromatogr** 1985 Jul 19;329(2):300–6

AROUSAL

Effect on postural sway of various benzodiazepine tranquillizers. Patat A, et al. **Br J Clin Pharmacol** 1985 Jul;20(1):9–16

Effects of a new benzodiazepine derivative, ethyl loflazepate (CM6912), on the arousal level of normal humans assessed by the averaged photopalpebral reflex. Tanaka M, et al. **Clin Neuropharmacol** 1985; 8(3):271–9

The conditioned place preference is affected by two independent reinforcement processes. White NM, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):37–42

Effects of the contraceptive pill on sedative responses to clonidine and apomorphine in normal women. Chalmers JS, et al. **Psychol Med** 1985 May;15(2):363–7

Evaluation of signal detection theory on the effects of psychotropic drugs on critical flicker-fusion frequency in normal subjects. MacNab MW, et al. **Psychopharmacology (Berlin)** 1985;85(4):431–5

ASSOCIATION

Mood-independent aberrancies in associative processes in bipolar affective disorder: an apparent stabilizing effect of lithium. Pons L, et al. **Psychiatry Res** 1985 Apr;14(4):315–22

ATTENTION

Effect of neuroleptic treatments on attention, information processing, and thought disorder. Spohn HE, et al. **Psychopharmacol Bull** 1985; 21(3):582-7

[A study on application of the function of maintaining concentration (TAF) for chronic schizophrenia] Okamoto Y, et al. **Hokkaido Igaku Zasshi** 1985 May;60(3):445-9 (Eng. Abstr.) **(Jpn)**

ATTENTION DEFICIT DISORDER WITH HYPERACTIVITY

Hyperactive children treated with stimulants. Is cognitive training a useful adjunct? Abikoff H, et al. **Arch Gen Psychiatry** 1985 Oct; 42(10):953-61

Methylphenidate and children with attention deficit disorder. Dose effects on classroom academic and social behavior. Pelham WE, et al. **Arch Gen Psychiatry** 1985 Oct;42(10):948-52

Treatment of hyperactive children with monoamine oxidase inhibitors. I. Clinical efficacy. Zametkin A, et al. **Arch Gen Psychiatry** 1985 Oct; 42(10):962-6

Treatment of hyperactive children with monoamine oxidase inhibitors. II. Plasma and urinary monoamine findings after treatment. Zametkin A, et al. **Arch Gen Psychiatry** 1985 Oct;42(10):969-73

Attention deficit disorder children with or without hyperactivity. Which behaviors are helped by stimulants? Ullmann RK, et al. **Clin Pediatr (Phila)** 1985 Oct;24(10):547-51

Pemoline pharmacokinetics and long term therapy in children with attention deficit disorder and hyperactivity. Collier CP, et al. **Clin Pharmacokinet** 1985 May-Jun;10(3):269-78

Treatment of chronic cocaine abuse and attention deficit disorder, residual type, with magnesium pemoline. Weiss RD, et al. **Drug Alcohol Depend** 1985 May;15(1-2):69-72

Separating psychological factors from brain trauma in treating a hyperactive child. Frances A, et al. **Hosp Community Psychiatry** 1985 Jul;36(7):711-3

Clonidine benefits children with attention deficit disorder and hyperactivity: report of a double-blind placebo-crossover therapeutic trial. Hunt RD, et al. **J Am Acad Child Psychiatry** 1985 Sep; 24(5):617-29

Developmental changes in the mother-child interactions of hyperactive boys: effects of two dose levels of Ritalin. Barkley RA, et al. **J Child Psychol Psychiatry** 1985 Sep;26(5):705-15

Catecholamine metabolism in the attention deficit disorder: implications for the use of amino acid precursor therapy. McConnell H. **Med Hypotheses** 1985 Aug;17(4):305-11

Ten years of experience with 1,000 hyperactive children in a private practice. Eichlseder W. **Pediatrics** 1985 Aug;76(2):176-84

Rate-dependency and hyperactivity: methylphenidate effects on operant responding. Rapport MD, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):77-83

Neuropharmacological basis of stimulant drug action in attention deficit disorder with hyperactivity: a review and synthesis. Solanto MV. **Psychol Bull** 1984 May;95(3):387-409 (195 ref.)

AUDITORY THRESHOLD

Effects of diazepam and triazolam on auditory and visual thresholds and reaction times in the baboon. Lukas SE, et al. **Psychopharmacology (Berlin)** 1985;87(2):167-72

AUTISM, INFANTILE

[Clinical (behavior scale items), electrophysiologic (conditioned evoked potentials) and biochemical (urinary homovanillic acid) markers in infantile autism] Barthelemy C, et al. **Encephale** 1985 May-Jun; 11(3):101-6 (33 ref.) (Eng. Abstr.) **(Fre)**

AVOIDANCE LEARNING

Relationship between the release and uptake of noradrenaline by rat brain synaptosomes in the formation of defensive conditioned reflex. Bazyan AS, et al. **Acta Neurobiol Exp (Warsz)** 1985;45(1-2):37-46

Memory effects of GABA-ergic antagonists in rats trained with two-way active avoidance tasks. Yonkov DI, et al. **Acta Physiol Pharmacol Bulg** 1985;11(2):44-9

Neocortical involvement in the acquisition and retention of learned alcohol aversions in rats. Kiefer SW, et al. **Alcohol** 1985 Jul-Aug; 2(4):597-601

Role of ethanol in conditioning aversion to alcoholic beverages in rats. Franchina JJ, et al. **Behav Res Ther** 1985;23(5):521-9

A response-specific conditioned aversion to rewarding hypothalamic stimulation in rats. Greenshaw AJ, et al. **Brain Res** 1985 Jul 22; 339(1):130-5

Comparisons between discrete lever-press and shuttle avoidance responses in mice: acquisition processes and effects of psychoactive drugs. Kuribara H, et al. **Jpn J Pharmacol** 1985 Jun;38(2):141-51

A comparison of physostigmine and soman using taste aversion and nociception. Romano JA, et al. **Neurobehav Toxicol Teratol** 1985 May-Jun;7(3):243-9

Effects of intracerebroventricular administration of ovine corticotropin-releasing factor (CRF 1-41) on passive avoidance behaviour: lack of influence on monoamine contents of limbic brain areas. Fekete M, et al. **Neuropeptides** 1985 Jul;6(4):283-292

Forebrain serotonergic involvement in avoidance learning. Ogren SO, et al. **Neurosci Lett** 1985 Aug 5;58(3):305-9

Central serotonin neurones in avoidance learning: interactions with noradrenaline and dopamine neurones. Ogren SO. **Pharmacol Biochem Behav** 1985 Jul;23(1):107-23

The role of trazodone metabolism in its inhibitory action on avoidance response. Sansone M, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):137-40

The effect of chronic administration of trazodone on the acquisition of avoidance behavior in mice. Sansone M, et al. **Pol J Pharmacol Pharm** 1985 Mar-Apr;37(2):173-8

Effects of phencyclidine on active avoidance and escape in rats. Martin P, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):237-40

The effect of stimulus preexposure upon the context effect in taste-aversion learning in noradrenaline-depleted rats. Archer T, et al. **Scand J Psychol** 1985;26(2):158-69

[Effect of a cyclic analog of enkephalin on learning and memory in the mouse] Getsova VM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug; 35(4):710-7 (Eng. Abstr.) **(Rus)**

AZEPINES

Worker exposure during aerial application of a liquid and a granular formulation of Ordram Selective Herbicide to rice. Knarr RD, et al. **Arch Environ Contam Toxicol** 1985 Sep;14(5):523-7

Spectrophotometric study of drugs containing the 1,4-diazepine-2-thione group. Fernández-Arciniega MA, et al. **Boll Chim Farm** 1985 Jan; 124(1):19-26

Effects of cetiedil on the oxidative metabolism of activated polymorphonuclear leucocytes. Kohzaki H, et al. **Br J Haematol** 1985 Jul;60(3):531-9

Relationship between alpha 2-adrenoceptor occupancy and response for B-HT 933 in canine saphenous vein. Ruffolo RR Jr, et al. **Eur J Pharmacol** 1985 May 8;111(2):267-71

Effect of the absorption enhancer, Azone, on the transport of 5-fluorouracil across hairless rat skin. Sugibayashi K, et al. **J Pharm Pharmacol** 1985 Aug;37(8):578-80

Characterization of alpha 2-adrenoceptor binding properties of imidazoline-like drugs, azoloazepine derivatives and beta-phenethylamine-like drugs in human platelet membranes. Vago T, et al. **J Pharm Pharmacol** 1985 Aug;37(8):593-6

Amelioration of albuminuria induced by dilazep administration in aminonucleoside nephrosis of rats. Nagase M, et al. **Nippon Jinzo Gakkai Shi** 1985 Mar;27(3):385-91

Sexual excitement and stretching and yawning induced by B-HT 920. Ferrari F. **Pharmacol Res Commun** 1985 Jun;17(6):557-64

Effect of dilazep on coronary and systemic circulations. Marzilli M, et al. **Pharmacology** 1985;31(2):82-7

BEHAVIOR

The effects of dietary neurotransmitter precursors on human behavior. Lieberman HR, et al. **Am J Clin Nutr** 1985 Aug;42(2):366-70

BEHAVIOR, ANIMAL

Effects of amiflamine and related compounds on the accumulation of biogenic monoamines in rat brain slices in vitro and ex vivo in relation to their behavioural effects. Rényi L, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):416-26

Effects of histamine and H1 and H2-receptor antagonists on the wet-dog-shaking episodes in rats induced with lithium chloride. Rajtar G, et al. **Acta Physiol Pol** 1984 Mar-Apr;35(2):131-5

Cholecystokinin potentiation of dopamine-mediated behaviors in the nucleus accumbens. Crawley JN. **Ann NY Acad Sci** 1985;448:283-92

Unilateral odor deprivation: effects on the development of olfactory bulb catecholamines and behavior. Brunjes PC, et al. **Brain Res** 1985 Sep; 354(1):1-6

In vivo voltammetric and behavioural evidence for somatodendritic autoreceptor control of mesolimbic dopamine neurones. Maidment NT, et al. **Brain Res** 1985 Jul 15;338(2):317-25

Behavioral study after local injection of 6-hydroxydopamine into the nucleus accumbens in the rat. Taghzouti K, et al. **Brain Res** 1985 Sep 30;344(1):9-20

Biochemical and behavioral changes in rats during and after chronic d-amphetamine exposure. Vogel WH, et al. **Drug Alcohol Depend** 1985 Jun;15(3):245-53

DSP-4 lesioning prevents the enhancement of dopamine and 5-hydroxytryptamine mediated behavioural changes by repeated electroconvulsive shock. Heal DJ, et al. **Eur J Pharmacol** 1985 Sep

10;115(1):117–21

Does a single priming injection of clenbuterol alter behavioral response to beta-adrenoceptor agonists and antagonists in mice through a time-dependent process? Martin P, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):91–6

Pharmacologic therapeutic window of pramiracetam demonstrated in behavior, EEG, and single neuron firing rates. Poschel BP, et al. **Experientia** 1985 Sep 15;41(9):1153–6

Behavioral and eegraphic changes induced by dopaminergic antidepressants in rabbits. Bo P, et al. **Farmaco [Sci]** 1985 Aug; 40(8):608–16

Differential biochemical and behavioral effects of single and chronic administration of amphetamine and apomorphine. Bernardi MM, et al. **Gen Pharmacol** 1985;16(4):407–10

Behavioral and neurochemical aspects of prostaglandins in brain function. Chiu EK, et al. **Gen Pharmacol** 1985;16(3):163–75 (115 ref.)

Differential vulnerability of male and female rats to the timing of various perinatal insults. Grimm VE, et al. **Int J Neurosci** 1985 Aug; 27(3–4):155–64

Source of stray voltage and effect on cow health and performance. Appleman RD, et al. **J Dairy Sci** 1985 Jun;68(6):1554–67 (40 ref.)

gamma-Aminobutyric acid metabolism and behavioral effects after intraventricular injection of spermine in chicks. Di Giorgio RM, et al. **J Neurochem** 1985 Sep;45(3):739–43

Cholecystokinin potentiates dopamine-mediated behaviors: evidence for modulation specific to a site of coexistence. Crawley JN, et al. **J Neurosci** 1985 Aug;5(8):1972–83

Rapid induction of supersensitivity to muscarinic antagonists-induced motor excitation by continuous stimulation of cholinergic receptors. Fernando JC, et al. **Life Sci** 1985 Sep 2;37(9):883–92

Quantification of dopaminergic supersensitization using apomorphine-induced behavior in the mouse. Randall PK. **Life Sci** 1985 Oct 14;37(15):1419–23

Sensitization to stress: the enduring effects of prior stress on amphetamine-induced rotational behavior. Robinson TE, et al. **Life Sci** 1985 Sep 16;37(11):1039–42

Animal models of behavioral pathology and violent aggression. Valzelli L. **Methods Find Exp Clin Pharmacol** 1985 Apr;7(4):189–93

The role of central dopaminergic systems in the behavioral effects of H-Phe-Ile-Tyr-His-Ser-Tyr-Lys-OH. Vécsei L, et al. **Neuropeptides** 1985 Jun;6(3):183–90

Intracerebroventricular administration of cholecystokinin inhibits the activity of the dopaminergic and serotoninergic systems of the brain. Vasar EE, et al. **Neurosci Behav Physiol** 1985 May–Jun;15(3):232–6

Acute and chronic behavioral interactions between phencyclidine (PCP) and amphetamine: evidence for a dopaminergic role in some PCP-induced behaviors. Greenberg BD, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):99–105

Behaviorally equivalent stressors differentially modify the monoamine altering property of d-amphetamine. Klauenberg BJ, et al. **Pharmacol Biochem Behav** 1985 Sep;23(3):417–23

A rapid and simple behavioural screening method for simultaneous assessment of limbic and striatal blocking effects of neuroleptic drugs. Ljungberg T, et al. **Pharmacol Biochem Behav** 1985 Sep; 23(3):479–85

Cathinone, cocaine and methamphetamine: similarity of behavioral effects. Schechter MD, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):913–6

Sexual excitement and stretching and yawning induced by B-HT 920. Ferrari F. **Pharmacol Res Commun** 1985 Jun;17(6):557–64

The 5-HT syndrome and the drug discrimination paradigm in rats: application in behavioral studies on the central 5-HT system. Ortmann R. **Pharmacopsychiatry** 1985 Mar;18(2):198–201

Influence of early beta-endorphin treatment on the behavior and reaction to beta-endorphin in the adult male rat. Meyerson BJ. **Psychoneuroendocrinology** 1985;10(2):135–47

Cholecystokinin potentiates dopamine-mediated behaviors in the nucleus accumbens, a site of CCK-DA co-existence. Crawley JN. **Psychopharmacol Bull** 1985;21(3):523–7

Serotonin-behavior interactions in vervet monkeys. McGuire MT, et al. **Psychopharmacol Bull** 1985;21(3):458–63

Stimulus control induced by benzodiazepine antagonist Ro 15-1788 in the rat. De Vry J, et al. **Psychopharmacology (Berlin)** 1985; 85(4):483–5

Circadian variation in behavioural responses to central 5-HT receptor stimulation in the mouse. Moser PC, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):223–7

Effects of d,l-propranolol on open field behavior of rats. Poli A, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):153–5

Comparison between the effects of propranolol and chlordiazepoxide on timing behaviour in the rat. Salmon P, et al. **Psychopharmacology (Berlin)** 1985;87(2):219–24

[Effects of prolonged methamphetamine treatment and its withdrawal on behavior and brain monoamine metabolism in mice] Odo S, et al. **Seishin Shinkeigaku Zasshi** 1985;87(3):155–75 (Eng. Abstr.) **(Jpn)**

[Effect of stress-inducing factors on the behavior of monkeys. I. The behavior of monkeys under acute emotional stress] Butovskaia ML, et al. **Biol Nauki** 1985;(6):67–74 (Eng. Abstr.) **(Rus)**

[Effect of the antioxidant dibunol and its combination with phenazepam on the behavior of rats in a conflict situation] Molodavkin GM, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):36–8 (Eng. Abstr.) **(Rus)**

[Behavior disorder in rats induced by Madopar and its pharmacological correction] Bondarenko NA, et al. **Farmakol Toksikol** 1985 Jul–Aug; 48(4):31–4 (Eng. Abstr.) **(Rus)**

[Emotional stress-induced changes in catecholamines in the nuclei of the brains of rats differing in 'open-field' behavior] Belova TI, et al. **Fiziol Zh SSSR** 1985 Jul;71(7):813–22 (Eng. Abstr.) **(Rus)**

[Effect of a derivative of GABA, phenibut, on behavior and the activity of visual cortex neurons of the rabbit during elaboration of a defensive reflex and internal inhibition] Shul'gina GI, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):695–702 (Eng. Abstr.)**(Rus)**

BENZAZEPINES

Blockade of renal effects of dopamine in the dog by the DA1 antagonist SCH 23390. Frederickson ED, et al. **Am J Physiol** 1985 Aug; 249(2 Pt 2):F236–40

Arylazide photoaffinity probe for alpha 2-adrenoceptors. Regan JW, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3667–72

Interactions between diltiazem and isoflurane. An in vitro investigation in isolated guinea pig atria. Broadbent MP, et al. **Br J Anaesth** 1985 Oct;57(10):1018–21

Effect of verapamil and diltiazem on calcium-dependent electrical activity in cardiac Purkinje fibres. Amerini S, et al. **Br J Pharmacol** 1985 May; 85(1):89–96

Vasomotor responses of cerebral arterioles in situ to putative dopamine receptor agonists. Edvinsson L, et al. **Br J Pharmacol** 1985 Jun; 85(2):403–10

The effect of diltiazem on noradrenaline release. Wolchinsky C, et al. **Br J Pharmacol** 1985 Jun;85(2):387–93

SCH 23390, a selective D1 dopamine receptor blocker, enhances the firing rate of nigral dopaminergic neurons but fails to activate striatal tyrosine hydroxylase. Onali P, et al. **Brain Res** 1985 Aug 5;340(1):1–7

Chemical transformation of protoberberines. VII. Efficient conversion of protoberberines into benzindenoazepines via 8,14-cycloberbines. Hanaoka M, et al. **Chem Pharm Bull (Tokyo)** 1985 Apr; 33(4):1434–43

Interaction of SCH 23390, a D-1-selective antagonist, with the anterior pituitary D-2 receptors and prolactin secretion in the rat. Apud JA, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):187–93

SCH-23390 antagonism of a D-2 dopamine agonist depends upon catecholaminergic neurons. Breese GR, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):109–14

Benzodiazepine receptor binding with a new ligand, Ro 22-8515. Goeders NE, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):147–8

SCH 23390, a selective dopamine D1 antagonist, activates dopamine neurons but fails to prevent their inhibition by apomorphine. Mereu G, et al. **Eur J Pharmacol** 1985 May 20;111(3):393–6

The effects of several ion channel blockers and calmodulin antagonists on fertilization-induced acid release and 45Ca2+ uptake in sea urchin eggs. Komukai M, et al. **Exp Cell Res** 1985 Aug;159(2):463–72

Improved recovery of cardiac function after 24 h of hypothermic arrest in the isolated rat heart: comparison of a prostacyclin analogue (ZK 36 374) and a calcium entry blocker (diltiazem). van Gilst WH, et al. **J Cardiovasc Pharmacol** 1985 May–Jun;7(3):520–4

Blocking effect of diltiazem on thiopentone-induced vasoconstriction in isolated canine internal carotid arteries. Tsuji T, et al. **J Cereb Blood Flow Metab** 1985 Sep;5(3):446–50

Diltiazem and desacetyldiltiazem analysis in human plasma using high-performance liquid chromatography: improved sensitivity without derivation. Abernethy DR, et al. **J Chromatogr** 1985 Jul 12; 342(1):216–20

Lack of effects of diltiazem on digoxin pharmacokinetics. Beltrami TR, et al. **J Clin Pharmacol** 1985 Jul–Aug;25(5):390–2

Binding of [3H]SCH23390 in rat brain: regional distribution and effects of assay conditions and GTP suggest interactions at a D1-like dopamine receptor. Schulz DW, et al. **J Neurochem** 1985 Nov;45(5):1601–11

Pharmacological analysis of the actions of SKF 82526 on cardiovascular dopamine receptors. Lokhandwala MF, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):337–44

Hyperactivity induced by stimulation of separate dopamine D-1 and D-2 receptors in rats with bilateral 6-OHDA lesions. Arnt J. **Life Sci** 1985 Aug 26;37(8):717–23

Effect of diltiazem on in vitro rabbit bladder function. Malkowicz SB, et al. **Pharmacology** 1985;31(1):24–33

[The antiaggregation effect of diltiazem] Alušík S, et al. **Vnitr Lek** 1985 Sep;31(9):877–81 (Eng. Abstr.) **(Cze)**

[Effect of calcium antagonists on physical fitness and metabolism] Kindermann W, et al. **Dtsch Med Wochenschr** 1985 Oct 25; 110(43):1657–61 (Eng. Abstr.) **(Ger)**

[Effect of intravenous administration of diltiazem on cerebral blood flow and brain function] Konishi T, et al. **No To Shinkei** 1985 Jun; 37(6):567–73 (Eng. Abstr.) **(Jpn)**

BENZODIAZEPINE TRANQUILIZERS

Psychomotor effects of alprazolam and diazepam during acute and subacute treatment, and during the follow-up phase. Aranko K, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):364-72

Benzodiazepine dependence: clinical and neurobiological aspects. Böning J. **Adv Biochem Psychopharmacol** 1985;40:185-92 (37 ref.)

Metabolism of ethyl loflazepate in the rat, the dog, the baboon and in man. Davi H, et al. **Arzneimittelforschung** 1985;35(7):1061-5

Topographic EEG changes with benzodiazepine administration in generalized anxiety disorder. Buchsbaum MS, et al. **Biol Psychiatry** 1985 Aug;20(8):832-42

Central effects during the continuous osmotic infusion of a benzodiazepine (triazolam). Breimer DD, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):807-15

Effects of end stage renal disease and aluminium hydroxide on triazolam pharmacokinetics. Kroboth PD, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):839-42

Effect on postural sway of various benzodiazepine tranquillizers. Patat A, et al. **Br J Clin Pharmacol** 1985 Jul;20(1):9-16

Single dose pharmacokinetics and pharmacodynamics of oral loprazolam in the elderly. Swift CG, et al. **Br J Clin Pharmacol** 1985 Aug; 20(2):119-28

Anxiety, performance and anti-anxiety drugs. Hindmarch I. **Br J Clin Pract [Symp Suppl]** 1985 May;38:53-8

An evaluation of alprazolam in the treatment of reactive or neurotic (secondary) depression. Imlah NW. **Br J Psychiatry** 1985 May; 146:515-9

Temazepam and the perceptual-motor performance of professional footballers. Golby J, et al. **Br J Sports Med** 1985 Jun;19(2):115-8

Clinical management of benzodiazepine dependence. Higgitt AC, et al. **Br Med J [Clin Res]** 1985 Sep 14;291(6497):688-90

A multi-centre, double-blind parallel trial of bromazepam ('Lexotan') and lorazepam to compare the acute benefit-risk ratio in the treatment of patients with anxiety. Cordingley GJ, et al. **Curr Med Res Opin** 1985; 9(7):505-10

The influence of H2 receptor antagonists on the plasma concentrations of midazolam and temazepam. Elliott P, et al. **Eur J Anaesthesiol** 1984 Sep;1(3):245-51

Inhibition of diazepam metabolism in microsomal- and perfused liver preparations of the rat by desmethyldiazepam, N-methyloxazepam and oxazepam. Savenije-Chapel EM, et al. **Eur J Drug Metab Pharmacokinet** 1985 Jan-Mar;10(1):15-20

Triazolam addiction [letter] Lynn EJ. **Hosp Community Psychiatry** 1985 Jul;36(7):779-80

Pharmacokinetic consequences of long term coadministration of cimetidine and triazolobenzodiazepines, alprazolam and triazolam, in healthy subjects. Pourbaix S, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Aug;23(8):447-51

Capillary gas-liquid chromatographic determination of the benzodiazepine triazolam in plasma using a retention gap. Baktir G, et al. **J Chromatogr** 1985 Apr 12;339(1):192-7

Determination of circulating ethyl loflazepate metabolites in the baboon by radio-high-performance liquid chromatography with injection of crude plasma samples: comparison with solvent extraction and thin-layer chromatography. Davi H, et al. **J Chromatogr** 1985 Jul 12; 342(1):159-65

Benzodiazepine dependence potential: current studies and trends. Smith DE. **J Subst Abuse Treat** 1984;1(3):163-7

Evaluation of the induction of hepatic drug-metabolizing enzymes in the rat and mouse treated with temazepam using trimethadione as the indicator. Kitagawa YF, et al. **J Toxicol Sci** 1985 Feb;10(1):21-8

Tolerance to the anticonvulsant action of benzodiazepines. Relationship to decreased receptor density. Rosenberg HC, et al. **Neuropharmacology** 1985 Jul;24(7):639-44

Experimental comparison of low doses of 1.5 mg fluspirilene and bromazepam in out-patients with psychovegetative disturbances. Hassel P. **Pharmacopsychiatry** 1985 Sep;18(5):297-302

5-Carboxylic derivatives of some 1,5-benzodiazepines. Nawojski A, et al. **Pol J Pharmacol Pharm** 1985 Jan-Feb;37(1):69-72

Comparative pharmacokinetics and pharmacodynamics of lorazepam, alprazolam and diazepam. Ellinwood EH Jr, et al. **Psychopharmacology (Berlin)** 1985;86(4):392-9

Benzodiazepines reduce the tolerance to reward delay in rats. Thiébot MH, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):147-52

Kinetic and pharmacological studies on estazolam in mice and man. Mancinelli A, et al. **Xenobiotica** 1985 Mar;15(3):257-65

[Clinical experience with bromazepam in endogenous depression] Náhunek K, et al. **Cesk Psychiatr** 1985 Aug;81(4):235-41 (Eng. Abstr.) **(Cze)**

[Treatment of masked depressions using bromazepam] Vencovský E, et al. **Cesk Psychiatr** 1985 Apr;81(2):75-8 (Eng. Abstr.) **(Cze)**

[Panic attacks treated with alprazolam (letter)] Andersen T. **Ugeskr Laeger** 1985 Jun 17;147(25):2014-5 **(Dan)**

[Validation of a method for detecting benzodiazepines in the urine by acid extraction of their benzophenones and thin layer chromatography] Vu Duc T, et al. **Ann Biol Clin (Paris)** 1985;43(3):261-5 (Eng. Abstr.) **(Fre)**

[Screening and detection of tetrazepam and its major metabolites] Schütz H, et al. **Arzneimittelforschung** 1985;35(7):1015-24 (Eng. Abstr.) **(Ger)**

[Clinical experiences with the new-generation anxiolytic agent cloxazolam--a double-blind study] Zmorski T, et al. **Schweiz Rundsch Med Prax** 1985 Jul 2;74(27):728-34 (Eng. Abstr.) **(Ger)**

BENZODIAZEPINONES

Mianserin is better tolerated and more effective in depression than a nomifensine-clobazam combination: a double-blind study. Levin A, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:75-80

Effects of single and repeated application of clonazepam and diazepam combined with cyproheptadine on apomorphine stereotypy in rats. Georgiev VP, et al. **Agressologie** 1985 Jan;26(1):57-60

Metabolism of ethyl loflazepate in the rat, the dog, the baboon and in man. Davi H, et al. **Arzneimittelforschung** 1985;35(7):1061-5

Carbachol stimulation of phosphatidic acid synthesis: competitive inhibition by pirenzepine in synaptosomes from rat cerebral cortex. Smith TL, et al. **Biochem Biophys Res Commun** 1985 Jul 16; 130(1):282-5

Single dose pharmacokinetics and pharmacodynamics of oral loprazolam in the elderly. Swift CG, et al. **Br J Clin Pharmacol** 1985 Aug; 20(2):119-28

A placebo controlled comparison of the effects of pirenzepine and amitriptyline on the tyramine pressor test in healthy volunteers. Wilkins MR, et al. **Br J Clin Pharmacol** 1985 Jun;19(6):829-31

The behavior of 1,4-benzodiazepine drugs in acidic media. II. Kinetics and mechanism of the acid-base equilibrium reaction of oxazolam. Kurono Y, et al. **Chem Pharm Bull (Tokyo)** 1985 Apr;33(4):1633-40

Effects of a new benzodiazepine derivative, ethyl loflazepate (CM6912), on the arousal level of normal humans assessed by the averaged photopalpebral reflex. Tanaka M, et al. **Clin Neuropharmacol** 1985; 8(3):271-9

Chlordiazepoxide-induced hyperphagia in non-food-deprived rats: effects of Ro15-1788, CGS 8216 and ZK 93 426. Cooper SJ, et al. **Eur J Pharmacol** 1985 May 28;112(1):39-45

Simple approach to assess potentiated drug combinations in clinical trials: studies with pirenzepine plus H2-receptor antagonists. Pöch G, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Jun;23(6):283-7

Determination of circulating ethyl loflazepate metabolites in the baboon by radio-high-performance liquid chromatography with injection of crude plasma samples: comparison with solvent extraction and thin-layer chromatography. Davi H, et al. **J Chromatogr** 1985 Jul 12; 342(1):159-65

Liquid chromatographic analysis of clonazepam in human serum with solid-phase (Bond-Elut) extraction. Kabra PM, et al. **J Chromatogr** 1985 Jun 14;341(2):383-90

Pro- and anti-convulsant drug effects in combination with the convulsant benzodiazepine Ro 5-4864. Pellow S, et al. **J Pharm Pharmacol** 1985 Aug;37(8):560-3

Reversal of slow-wave sleep by benzodiazepine antagonist Ro 15-1788 [letter] Ziegler G, et al. **Lancet** 1985 Aug 31;2(8453):510

Differences between the tolerance characteristics of two anticonvulsant benzodiazepines. Gent JP, et al. **Life Sci** 1985 Sep 2;37(9):849-56

Effects of the 1,5-benzodiazepine clobazam on pituitary hormones in the male rat. Valli M, et al. **Methods Find Exp Clin Pharmacol** 1985 Apr; 7(4):179-81

Molecular structure of Ro15-1788 and a model for the binding of benzodiazepine receptor ligands. Structural identification of common features in antagonists. Codding PW, et al. **Mol Pharmacol** 1985 Aug; 28(2):178-84

Pirenzepine indicates heterogeneity of muscarinic receptors linked to cerebral inositol phospholipid metabolism. Lazareno S, et al. **Neuropharmacology** 1985 Jun;24(6):593-5

Selective blockade of benzodiazepine receptors by Ro 15-1788 prevents foot shock-induced decrease of low affinity gamma-aminobutyric acid receptors. Corda MG, et al. **Neurosci Lett** 1985 May 23;56(3):265-9

Reduction of inhibition by a benzodiazepine antagonist, Ro15-1788, in the rat hippocampal slice. King GL, et al. **Neuroscience** 1985 Jun; 15(2):371-8

Benzodiazepine-receptor mediated inhibition of isolation-induced aggression in mice. Skolnick P, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):17-20

Initial study of methylclonazepam in generalized anxiety disorder. Evidence for greater power in the cross-over design. Ansseau M, et al. **Psychopharmacology (Berlin)** 1985;87(2):130-5

Stimulus control induced by benzodiazepine antagonist Ro 15-1788 in the rat. De Vry J, et al. **Psychopharmacology (Berlin)** 1985; 85(4):483-5

Effects of valproate on hyponeophagia in rats: competitive antagonism with picrotoxin and non-competitive antagonism with RO 15-1788. Shephard RA, et al. **Psychopharmacology (Berlin)** 1985;86(3):313-7

Characterization of pirenzepine interaction with cytochrome P-450. Rendić S, et al. **Xenobiotica** 1985 May;15(5):399-405

Correlation of the clinical pharmacodynamics of loprazolam with serum concentration. Stevens LA, et al. **Xenobiotica** 1985 Jul;15(7):623–31

[Screening and detection of tetrazepam and its major metabolites] Schütz H, et al. **Arzneimittelforschung** 1985;35(7):1015–24 (Eng. Abstr.) **(Ger)**

[Clinical experiences with the new-generation anxiolytic agent cloxazolam—a double-blind study] Zmorski T, et al. **Schweiz Rundsch Med Prax** 1985 Jul 2;74(27):728–34 (Eng. Abstr.) **(Ger)**

[Effect of the antioxidant dibunol and its combination with phenazepam on the behavior of rats in a conflict situation] Molodavkin GM, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):36–8 (Eng. Abstr.) **(Rus)**

[The role of changes in the antioxidative activity and phospholipid composition of the rat liver in the mechanism of phenazepam action on the liver and the protective effect of talamonal] Molochkina EM, et al. **Vopr Med Khim** 1985 May–Jun;31(3):17–21 (Eng. Abstr.) **(Rus)**

BIOGENIC AMINES

Effects of amiflamine and related compounds on the accumulation of biogenic monoamines in rat brain slices in vitro and ex vivo in relation to their behavioural effects. Rényi L, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):416–26

Ontogenetic development of the monoamine oxidase activity and of the metabolism of biogenic monoamines in rat brain. Stancheva S, et al. **Acta Physiol Pharmacol Bulg** 1985;11(1):3–9

Effect of tocainide on the concentrations of norepinephrine dopamine, serotonin and histamine in rat brain and its binding affinity to neuroceptors. Przuntek H, et al. **Arzneimittelforschung** 1985; 35(5):787–9

Late changes in cerebral monoamine metabolism following focal ventrolateral cerebrocortical lesions in rats. Finklestein S, et al. **Brain Res** 1985 Oct 7;344(2):205–10

Monoamine-induced responses in lateral septal neurons: influence of iontophoretically applied vasopressin. Joëls M, et al. **Brain Res** 1985 Sep 30;344(1):120–6

Epinephrine accumulation in rat brain after chronic administration of pargyline and LY 51641—comparison with other brain amines. Mefford IN, et al. **Brain Res** 1985 Jul 29;339(2):342–5

Long-term effects of repeated methylamphetamine administration on monoamine neurons in the rhesus monkey brain. Preston KL, et al. **Brain Res** 1985 Jul 15;338(2):243–8

Monoamine release from dopamine-depleted rat caudate nucleus reinnervated by substantia nigra transplants: an in vivo electrochemical study. Rose G, et al. **Brain Res** 1985 Aug 19;341(1):92–100

Monoamine, amino acid and cholinergic interactions in slices of rat cerebral cortex. Flint RS, et al. **Brain Res Bull** 1985 Aug; 15(2):197–202

Three dimensional analysis of retinal neuropeptides and amine in the chick. Kiyama H, et al. **Brain Res Bull** 1985 Aug;15(2):155–65

The effect of tryptophan on biogenic amines in the hepatic portal circulation of the dog. Hussain MN, et al. **Can J Physiol Pharmacol** 1985 Jul;63(7):863–6

The effect of growth hormone on biogenic amines in the hepatic portal circulation of the dog. Hussain MN, et al. **Can J Physiol Pharmacol** 1985 May;63(5):463–7

Modification of the effects of repetitive restraint stress on brain biogenic amines by L-tyrosine. Quirce CM, et al. **Chung Kuo Yao Li Hsueh Pao** 1984 Dec;5(4):226–8

Repetitive measurement of monoamine metabolite levels in cerebrospinal fluid of conscious rats: effects of reserpine and haloperidol. Scheinin H, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):345–51

Electrochemical detection of biogenic amines following acylation by N-hydroxysuccinimide esters. Jacobson KA, et al. **FEBS Lett** 1985 Sep 2;188(2):307–11

Peptidergic and aminergic innervation of the facial nucleus of the rat with special reference to ontogenetic development. Senba E, et al. **J Comp Neurol** 1985 Aug 22;238(4):429–39

Effects of rolipram, a novel antidepressant, on monoamine metabolism in rat brain. Kehr W, et al. **J Neural Transm** 1985;63(1):1–12

Monoamine distribution on the ventral surface of the rat medulla oblongata. Smialowska M, et al. **J Neural Transm** 1985;63(1):13–29

Postmortem changes in catecholamines, indoleamines, and their metabolites in rat brain regions: prevention with 10-kW microwave irradiation. Ikarashi Y, et al. **J Neurochem** 1985 Sep;45(3):935–9

Sulfate conjugation of monoamines in human brain: purification and some properties of an arylamine sulfotransferase from cerebral cortex. Yu PH, et al. **J Neurochem** 1985 Sep;45(3):836–43

The sensitivity of GABA-receptor is increased by biogenic amines. Koketsu K, et al. **Kurume Med J** 1984;31(4):331–4

Effects of intracerebroventricular administration of ovine corticotropin-releasing factor (CRF 1-41) on passive avoidance behaviour: lack of influence on monoamine contents of limbic brain areas. Fekete M, et al. **Neuropeptides** 1985 Jul;6(4):283–292

Sensation seeking, mania, and monoamines. Zuckerman M. **Neuropsychobiology** 1985;13(3):121–8

Behaviorally equivalent stressors differentially modify the monoamine altering property of d-amphetamine. Klauenberg BJ, et al. **Pharmacol Biochem Behav** 1985 Sep;23(3):417–23

Somatostatin mediates the effect of growth hormone surges on splanchnic biogenic amines. Hussain MN, et al. **Proc Soc Exp Biol Med** 1985 Sep; 179(4):517–21

Rhesus monkey cerebrospinal fluid amine metabolite changes following treatment with the reversible monoamine oxidase type-A inhibitor cimoxatone. Garrick NA, et al. **Psychopharmacology (Berlin)** 1985; 86(3):265–9

Effect of repeated dietary exposure of aflatoxin B1 on brain biogenic amines and metabolites in the rat. Coulombe RA Jr, et al. **Toxicol Appl Pharmacol** 1985 Sep 30;80(3):496–501

Prenatal carbon monoxide exposure differentially affects postnatal weight and monoamine concentration of rat brain regions. Storm JE, et al. **Toxicol Appl Pharmacol** 1985 Oct;81(1):139–46

[Changes in the CSF levels of monoamine metabolites in 102 chronic schizophrenic patients following probenecid before and after neuroleptic medication] Chen YF. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Oct; 17(5):273–7 (Eng. Abstr.) **(Chi)**

[Differential voltametry: a new method for studying the cerebral metabolism of monoamines] Pujol JF. **J Pharmacol** 1985; 16 Suppl 1:33–50 (Eng. Abstr.) **(Fre)**

[Effects of prolonged methamphetamine treatment and its withdrawal on behavior and brain monoamine metabolism in mice] Odo S, et al. **Seishin Shinkeigaku Zasshi** 1985;87(3):155–75 (Eng. Abstr.) **(Jpn)**

[Anticonvulsant action of a thyrotropin-releasing hormone analog (DN-1417) and changes in brain monoamines] Sato M, et al. **Seishin Shinkeigaku Zasshi** 1985;87(3):176–85 **(Jpn)**

[Localization of biogenic monoamines in the dura mater of the rat brain] Motavkin PA, et al. **Arkh Anat Gistol Embriol** 1985 May;88(5):11–6 (Eng. Abstr.) **(Rus)**

[Effect of 7-hydroxygluacine on brain biogenic monoamines] Petkov VD, et al. **Farmakol Toksikol** 1985 May–Jun;48(3):19–22 (Eng. Abstr.) **(Rus)**

[Effect of 24-hour sleep deprivation on the metabolism of biogenic amines] Bol'shkova TD, et al. **Fiziol Cheloveka** 1985 Jul–Aug;11(4):652–6 **(Rus)**

[Change in certain forms of aggressive behavior and the concentration of monoamines in the brain during selection of wild rats for taming] Nikulina EM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):703–9 (Eng. Abstr.) **(Rus)**

BIPOLAR DISORDER

Clinical and laboratory effects of discontinuation of lithium prophylaxis. Goodnick PJ. **Acta Psychiatr Scand** 1985 Jun;71(6):608–14

Depression and anxiety: mianserin and nomifensine compared in a double-blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67–74

Hematological effects of carbamazepine in patients with affective illness. Joffe RT, et al. **Am J Psychiatry** 1985 Oct;142(10):1196–9

CSF substance P immunoreactivity in affective disorders. Berrettini WH, et al. **Biol Psychiatry** 1985 Sep;20(9):965–70

Rapid antidepressant activity of destyr gamma endorphin: correlation with urinary melatonin. Chazot G, et al. **Biol Psychiatry** 1985 Sep; 20(9):1026–30

An open clinical trial of carbamazepine in treatment-resistant bipolar and schizo-affective psychotics. Elphick M. **Br J Psychiatry** 1985 Aug; 147:198–200

Treatment of rapid cycling affective illness [letter] Lowe MR. **Br J Psychiatry** 1985 May;146:558

Carbamazepine in manic depressive psychosis. Arap Mengech HN. **East Afr Med J** 1985 Mar;62(3):172–4

Spontaneous afternoon plasma cortisol in depression. Christensen P, et al. **J Affective Disord** 1985 May–Jun;8(3):271–8

The use of sodium valproate, carbamazepine and oxcarbazepine in patients with affective disorders. Emrich HM, et al. **J Affective Disord** 1985 May–Jun;8(3):243–50

Lithium prophylaxis of recurrent affective disorders. Glen AI. **J Affective Disord** 1985 May–Jun;8(3):259–65

Lithium dosage in the elderly. A study with matched age groups. Greil W, et al. **J Affective Disord** 1985 Jul;9(1):1–4

Dopamine in manic depressive illness. A pharmacological synthesis. Silverstone T. **J Affective Disord** 1985 May–Jun;8(3):225–31

Alternative therapies for bipolar disorder. Lerer B. **J Clin Psychiatry** 1985 Aug;46(8):309–16 (93 ref.)

Developmental manifestations in a boy with prepubertal bipolar disorder. Reiss AL. **J Clin Psychiatry** 1985 Oct;46(10):441–3

L-phenylalanine [letter] Simonson M. **J Clin Psychiatry** 1985 Aug; 46(8):355

Treatment of bulimia and rapid-cycling bipolar disorder with sodium valproate: a case report. Herridge PL, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):229–30

Factors associated with response to lithium prophylaxis in DSM III major depression and bipolar disorder. Maj M, et al. **Pharmacopsychiatry** 1985 Sep;18(5):309-13

A controlled study of cellular immune function in affective disorders before and during somatic therapy. Albrecht J, et al. **Psychiatry Res** 1985 Jul;15(3):185-93

Illness behaviour and rehospitalization in bipolar affective disorder. Joyce PR. **Psychol Med** 1985 Aug;15(3):521-5

Side-effects of lithium at lower therapeutic levels: the significance of thirst. King JR, et al. **Psychol Med** 1985 May;15(2):355-61

Investigating renal function during lithium treatment. Waller DG, et al. **Psychol Med** 1985 May;15(2):369-75

Dopamine receptor binding of C-11-3-N-methylspiperone in the caudate in schizophrenia and bipolar disorder: a preliminary report. Wong DF, et al. **Psychopharmacol Bull** 1985;21(3):595-8

[Clinical study of 86 cases of manic-depressive psychosis] Cai JB. **Chung Hua I Hsueh Tsa Chih** 1985 Jun;65(6):325-8 (Eng. Abstr.) **(Chi)**

[A clinical study of 456 cases of manic-depressive disorder] Sun JW. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Aug; 17(4):236-8 (Eng. Abstr.) **(Chi)**

[Lithium levels in biological media and treatment surveillance] Greffe J, et al. **Encephale** 1985 Mar-Apr;11(2):79-83 (Eng. Abstr.) **(Fre)**

[Therapy of depressive and manic diseases] Seige D. **Psychiatr Neurol Med Psychol Beih** 1966;4-5:186-92 **(Ger)**

[Family interactions and adherence to lithium pharmacotherapy] de León OA, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):7-16 (Eng. Abstr.) **(Spa)**

BLOOD-BRAIN BARRIER

Enhanced cerebrovascular permeability by Metrazol: significance for brain metastases. Greig N, et al. **Clin Exp Metastasis** 1983 Jan-Mar; 1(1):83-95

BRADYKININ

Control of sodium and potassium transport in the cortical collecting duct of the rat. Effects of bradykinin, vasopressin, and deoxycorticosterone. Tomita K, et al. **J Clin Invest** 1985 Jul;76(1):132-6

In vivo and in vitro effects of bradykinin on the release of beta-endorphin-like immunoreactivity. Matsumura M, et al. **Neuroendocrinology** 1985 Aug;41(2):101-6

[The effect of bradykinin on free nitrogen compounds and energy production in the rat brain] Hashimoto Y, et al. **Shikwa Gakuho** 1985 Mar;85(3):371-9 (Eng. Abstr.) **(Jpn)**

BUTYLAMINES

Biotransformation of terodiline. II. Disposition in the male rat. Identification of metabolites in rat urine and rat liver microsomes by mass spectrometry. Norén B, et al. **Acta Pharm Suec** 1985; 22(3):131-46

Comparison of the calcium-antagonistic effects of terodiline, nifedipine and verapamil. Larsson-Backström C, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 Jul;57(1):8-17

Biotransformation of terodiline I. Identification of metabolites in dog urine by mass spectrometry. Norén B, et al. **Biomed Mass Spectrom** 1985 Aug;12(8):367-79

Determination of diprobutine in human plasma using gas-liquid chromatography with nitrogen-selective detection. Davies CL, et al. **J Chromatogr** 1985 Apr 12;339(1):186-91

BUTYROPHENONE TRANQUILIZERS

Treatment of rapid cycling affective illness [letter] Lowe MR. **Br J Psychiatry** 1985 May;146:558

Sensitive analysis of butyrophenone neuroleptics by high-performance liquid chromatography with ultraviolet detection at 254 am. Parkinson D. **J Chromatogr** 1985 Jun 14;341(2):465-72

[Evaluation of the efficacy of haloperidol decanoate in the treatment of chronic psychotic hospital patients] Marchant N, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):37-41 (Eng. Abstr.) **(Spa)**

BUTYROPHENONES

Effects of phospholipids on the specific binding of [3H]spiroperidol to the cholate extract of rat brain synaptic membranes. Moroi K, et al. **Int J Biochem** 1985;17(5):637-44

Changes of the striatal 3H-spiperone binding 3-6 weeks after nigrostriatal denervation and after two years. Guerin B, et al. **Life Sci** 1985 Sep 9;37(10):953-61

Dopamine receptor binding of C-11-3-N-methylspiperone in the caudate in schizophrenia and bipolar disorder: a preliminary report. Wong DF, et al. **Psychopharmacol Bull** 1985;21(3):595-8

Prolonged antidopaminergic actions of single doses of butyrophenones in the rat. Campbell A, et al. **Psychopharmacology (Berlin)** 1985; 87(2):161-6

[The affinity of aromatic fluoride derivatives of phenothiazine neuroleptics to spiroperidol binding sites of dopamine receptors by the radioligand technic in vitro] Oelssner W Jr, et al. **Pharmazie** 1985 May; 40(5):341-2 (Eng. Abstr.) **(Ger)**

CARBAMAZEPINE

Hematological effects of carbamazepine in patients with affective illness. Joffe RT, et al. **Am J Psychiatry** 1985 Oct;142(10):1196-9

An open clinical trial of carbamazepine in treatment-resistant bipolar and schizo-affective psychotics. Elphick M. **Br J Psychiatry** 1985 Aug; 147:198-200

Use of carbamazepine in psychiatric disorders. Birkhimer LJ, et al. **Clin Pharm** 1985 Jul-Aug;4(4):425-34

Plasma concentrations of carbamazepine and carbamazepine 10,11-epoxide during pregnancy and after delivery. Battino D, et al. **Clin Pharmacokinet** 1985 May-Jun;10(3):279-84

Carbamazepine in manic depressive psychosis. Arap Mengech HN. **East Afr Med J** 1985 Mar;62(3):172-4

Practical therapeutics: the use of carbamazepine in affective disorders. Ouel AO, et al. **East Afr Med J** 1985 Mar;62(3):224-8

Relative bioavailability of rectally administered carbamazepine suspension in humans. Graves NM, et al. **Epilepsia** 1985 Sep-Oct;26(5):429-33

Chronic carbamazepine treatment increases brain adenosine receptors. Marangos PJ, et al. **Epilepsia** 1985 Sep-Oct;26(5):493-8

Antinociceptive effect of intracisternal carbamazepine evidenced by the bradykinin-induced biting-like response in rats. Foong FW, et al. **Exp Neurol** 1985 Oct;90(1):264-7

The use of sodium valproate, carbamazepine and oxcarbazepine in patients with affective disorders. Emrich HM, et al. **J Affective Disord** 1985 May-Jun;8(3):243-50

Successful treatment of psychotic depression with carbamazepine. Schaffer CB, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):233-5

Bioequivalence of carbamazepine chewable and conventional tablets: single-dose and steady-state studies. Chan KK, et al. **J Pharm Sci** 1985 Aug;74(8):866-70

Overflow urinary incontinence due to carbamazepine. Anders RJ, et al. **J Urol** 1985 Oct;134(4):758-9

Side-effects induced by carbamazepine-10,11-epoxide [letter] Patsalos PN, et al. **Lancet** 1985 Aug 31;2(8453):496

Neuronal sensitivity to substance P is increased after repeated treatment with tranylcypromine, carbamazepine or oxaprotaline, but decreased after repeated electroconvulsive shock. Jones RS, et al. **Neuropharmacology** 1985 Jul;24(7):627-33

The central action of carbamazepine as a potential antidepressant drug. Maj J, et al. **Pol J Pharmacol Pharm** 1985 Jan-Feb;37(1):47-56

Therapeutic indications in carbamazepine overdose. Kossoy AF, et al. **South Med J** 1985 Aug;78(8):999-1000

Carbamazepine and carbamazepine-epoxide serum protein binding in newborn infants. Groce JB 3d, et al. **Ther Drug Monit** 1985; 7(3):274-6

Carbamazepine protein binding and disposition in pregnancy. Yerby MS, et al. **Ther Drug Monit** 1985;7(3):269-73

Carbamazepine and psychotherapy in the treatment of schizoaffective psychosis. Cegalis JA, et al. **Yale J Biol Med** 1985 Jul-Aug; 58(4):327-36

CARBIDOPA

Metabolism of carbidopa to alpha-methyldopamine and alpha-methylnorepinephrine in rats. Shelton RC, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3623-6

Peripheral carbidopa affects striatal monoamine oxidase activity [letter] LeWitt PA, et al. **Neurology** 1985 Aug;35(8):1258-9

CATALEPSY

[Changes in the serotonin system of the brains of rats genetically predisposed to catalepsy] Popova NK, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):742-6 (Eng. Abstr.) **(Rus)**

CATECHOL ESTROGENS

Effect of intraventricular administration of catechol estrogens on catecholamine content in various brain regions. Panek DU, et al. **Brain Res** 1985 Aug 5;340(1):87-90

Catechol oestradiol control of FSH-stimulated granulosa cell steroidogenesis. Hudson KE, et al. **J Endocrinol** 1985 Jul; 106(1):R1-4

HPLC-ECD procedure for the measurement of O-methylation of catechol estrogens by vascular tissue. Reid JJ, et al. **J Pharmacol Methods** 1985 Aug;14(1):25-39

CATECHOLAMINES

Urinary catecholamines in iron-deficient rats at rest and following surgical stress. Groeneveld D, et al. **Am J Clin Nutr** 1985 Aug;42(2):263-9

Application of the dual-cell coulometric detector: a method for assaying monoamines and their metabolites. Achilli G, et al. **Anal Biochem** 1985 Jul;148(1):1–9

Plasma catecholamine concentrations in acute states of stress and trauma [letter] Little RA, et al. **Arch Emerg Med** 1985 Mar;2(1):46–7

Enhancement of acetylcholine–evoked catecholamine release from perfused dog adrenals by elevating cyclic AMP levels. Morita K, et al. **Arch Int Pharmacodyn Ther** 1985 Jun;275(2):208–16

Inhibitory effect of hyperosmolality on catecholamine secretion from the bovine adrenal medulla. Pinto JE, et al. **Arch Int Pharmacodyn Ther** 1985 Aug;276(2):236–46

Catecholamine regulation of neocortical spindling in DBA/2 mice. Ryan LJ. **Behav Brain Res** 1985 Aug;16(2–3):103–15

Effects of debrisoquin on the excretion of catecholamine and octopamine metabolites in the rat and guinea pig. Edwards DJ, et al. **Biochem Pharmacol** 1985 Aug 15;34(16):2911–6

Conjugated catecholamines and pressor responses to angiotensin, luteinizing hormone–releasing hormone and prazosin in conscious toads. Wilson JX. **Br J Pharmacol** 1985 Jul;85(3):647–53

Regional distribution of catecholaminergic terminals in the pigeon visual system. Bagnoli P, et al. **Brain Res** 1985 Jul 1;337(2):277–86

Unilateral odor deprivation: effects on the development of olfactory bulb catecholamines and behavior. Brunjes PC, et al. **Brain Res** 1985 Sep; 354(1):1–6

Effect of intraventricular administration of catechol estrogens on catecholamine content in various brain regions. Panek DU, et al. **Brain Res** 1985 Aug 5;340(1):87–90

Catecholaminergic fiber sprouting in granuloprival coeruleo–cerebellar cultures. Seil FJ, et al. **Brain Res** 1985 Aug;353(2):251–5

Catecholaminergic innervation of the rat adrenal cortex. Kleitman N, et al. **Cell Tissue Res** 1985;241(1):139–47

Interference of labetalol metabolites in the determination of plasma catecholamines by HPLC with electrochemical detection. Bouloux PM, et al. **Clin Chim Acta** 1985 Aug 15;150(2):111–7

The effects of piretanide on catecholamine metabolism, plasma renin activity and plasma aldosterone: a double–blind study versus furosemide in healthy volunteers. Verho M, et al. **Curr Med Res Opin** 1985; 9(7):461–74

Genetic variation in catecholamine responsive metabolic pathways—a hypothesis for a common regulatory mechanism in BALB/c sublines. Kozak LP. **Curr Top Microbiol Immunol** 1985;122:66–70

Partial expression of catecholaminergic traits in cholinergic chick ciliary ganglia: studies in vivo and in vitro. Iacovitti L, et al. **Dev Biol** 1985 Aug;110(2):402–12

Biochemical and behavioral changes in rats during and after chronic d–amphetamine exposure. Vogel WH, et al. **Drug Alcohol Depend** 1985 Jun;15(3):245–53

Circadian variations of free and sulfoconjugated catecholamines in normal subjects. Kuchel O, et al. **Endocr Res** 1985;11(1–2):17–25

Angiotensin II restoration of reflex adrenal medullary secretion to anephric dogs is physiologically dose dependent. Badder EM, et al. **Endocrinology** 1985 Nov;117(5):1920–9

Effects of TRH and a rat TSH preparation on discrete hypothalamic and forebrain catecholamine nerve terminal networks in the hypophysectomized male rat. Andersson K, et al. **Eur J Pharmacol** 1985 May 20;111(3):295–307

Involvement of amygdaloid catecholaminergic mechanism in suppressive effects of desipramine and imipramine on duration of immobility in rats forced to swim. Araki H, et al. **Eur J Pharmacol** 1985 Jul 31; 113(3):313–8

The importance of the alpha–adrenoceptor agonist activity of dobutamine to inotropic selectivity in the anaesthetized cat. Kenakin TP, et al. **Eur J Pharmacol** 1985 May 20;111(3):347–54

Effects of catecholamines, monophenolamines and phenylamines on identifiable giant neurons of an African giant snail (Achatina fulica Férussac). Ku BS, et al. **Eur J Pharmacol** 1985 Aug 7;114(1):1–8

Sources of the catecholaminergic innervation of the trigeminal nucleus caudalis in cat. Stevens RT, et al. **Exp Neurol** 1985 Oct; 90(1):215–23

Phorbol ester stimulates catecholamine synthesis in isolated bovine adrenal medullary cells. Houchi H, et al. **FEBS Lett** 1985 Sep 2; 188(2):205–8

Catecholamine effects on blood pressure and heart rate in warm– and cold–acclimated American bullfrogs (Rana catesbeiana). Herman CA, et al. **Gen Comp Endocrinol** 1985 Sep;59(3):434–41

Quantitation and immunohistochemistry of catecholamines in the posterior segment of the eye. Ehinger B, et al. **Histochemistry** 1985; 82(5):435–9

The neurochemistry of mania. The effect of lithium on catecholamines, indoleamines and calcium mobilization. Wood K. **J Affective Disord** 1985 May–Jun;8(3):215–23

Free, glucuronide, and sulfate catecholamines in the rat: effect of hypoxia. Claustre J, et al. **J Appl Physiol** 1985 Jul;59(1):12–7

Modification of dobutamine– and terbutaline–induced calcium and fluid secretion from rat salivary glands by atenolol and butoxamine. Schneyer CA, et al. **J Auton Nerv Syst** 1985 Aug;13(4):275–85

Determination of adult sheep plasma catecholamines using [3H]norepinephrine as the internal standard. Boylan JM, et al. **J Chromatogr** 1985 Feb 27;338(1):192–4

Ventricular myocardial catecholamines in primates. Pierpont GL, et al. **J Lab Clin Med** 1985 Aug;106(2):205–10

CSF sulfoconjugated catecholamines in man: their relationship with plasma catecholamines. Kuchel O, et al. **J Neural Transm** 1985; 62(1–2):91–7

Postmortem changes in catecholamines, indoleamines, and their metabolites in rat brain regions: prevention with 10–kW microwave irradiation. Ikarashi Y, et al. **J Neurochem** 1985 Sep;45(3):935–9

Metabolic aspects of spinal cord injuries. Northrup BE. **J Neurosurg Sci** 1984 Jul–Dec;28(3–4):121–5

Spectrophotometric determination of catecholamines. Basyoni Salem F. **J Pharm Belg** 1985 May–Jun;40(3):185–90

Effect of 6–hydroxydopamine on the metabolism of endogenous octopamines and catecholamines. Ibrahim KE, et al. **J Pharm Pharmacol** 1985 Jul;37(7):496–7

The affinity and efficacy of naturally occurring catecholamines at beta–adrenoceptor subtypes. McPherson GA, et al. **J Pharm Pharmacol** 1985 Jul;37(7):499–501

Effect of epidural morphine on urinary catecholamine excretion during postoperative period. Yasuda S, et al. **Keio J Med** 1985 Mar; 34(1):25–9

Comparison of the effects of neuropeptide Y and adrenergic transmitters on LH release and food intake in male rats. Allen LG, et al. **Life Sci** 1985 Aug 19;37(7):617–23

Catecholamine metabolism in the attention deficit disorder: implications for the use of amino acid precursor therapy. McConnell H. **Med Hypotheses** 1985 Aug;17(4):305–11

Interactions of microtubule–active agents with nicotinic acetylcholine receptors. Relationship to their inhibition of catecholamine secretion by adrenal chromaffin cells. McKay DB, et al. **Mol Pharmacol** 1985 Jul;28(1):10–6

Adrenergic stimulation of pepsinogen release from rabbit isolated gastric glands. Skoubo–Kristensen E, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jul;330(1):37–41

Electrophysiological interactions between haloperidol and reduced haloperidol, and dopamine, norepinephrine and phencyclidine in rat brain. Kirch DG, et al. **Neuropharmacology** 1985 May;24(5):375–9

Effect of catecholamines on the activity of rat brain dipeptidyl aminopeptidase. Imai K, et al. **Neurosci Res** 1984 Oct;1(5):353–6

New dopaminergic terminal fields in the motor, visual (area 18b) and retrosplenial cortex in the young and adult rat. Immunocytochemical and catecholamine histochemical analyses. Berger B, et al. **Neuroscience** 1985 Aug;15(4):983–98

Dietary carbohydrate intake and catecholamine secretion in man. **Nutr Rev** 1985 May;43(5):138–40 (12 ref.)

The chromaffin vesicle: a model secretory organelle. Njus D, et al. **Physiologist** 1985 Aug;28(4):235–41 (53 ref.)

Changes in plasma proenkephalin peptide F and catecholamine levels during graded exercise in men. Kraemer WJ, et al. **Proc Natl Acad Sci USA** 1985 Sep;82(18):6349–51

Effect of various catecholamine antagonists on prolactin secretion in conscious male rabbits. Kaji H, et al. **Proc Soc Exp Biol Med** 1985 Oct;180(1):144–8

Peptide–catecholamine interaction: feeding and satiety. Myers RD. **Psychopharmacol Bull** 1985;21(3):406–11

Amphetamine–induced enhancement of ethanol consumption: role of central catecholamines. Levy AD, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):233–6

Association between learning and cortical catecholamines in non–drug–treated rats. Sahakian BJ, et al. **Psychopharmacology (Berlin)** 1985;86(3):339–43

Cardiotonic agents: a simple HPLC procedure for the quantitation of dobutamine and a new congener in plasma. Dixon R, et al. **Res Commun Chem Pathol Pharmacol** 1985 May;48(2):313–6

Effects of hypoxia on catecholamine and cardiorespiratory responses in exercising dogs. Favier RJ, et al. **Respir Physiol** 1985 Aug; 61(2):167–77

The adrenal chromaffin cell. Carmichael SW, et al. **Sci Am** 1985 Aug; 253(2):40–9

[Stress and the excretion of catecholamines in patients after kidney transplantation] Honzák R, et al. **Cas Lek Cesk** 1985 Jul 19; 124(29):912–3 (Eng. Abstr.) **(Cze)**

[Catecholaminergic receptors of the blood cells of schizophrenics] Ackenheil M, et al. **Encephale** 1985 May–Jun;11(3):95–100 (Eng. Abstr.) **(Fre)**

[Levels of free and conjugated catecholamines in amniotic fluid and in umbilical and maternal blood in patients undergoing cesarean section] Bardazzi N, et al. **Quad Sclavo Diagn** 1984 Dec;20(4):364–71 (Eng. Abstr.) **(Ita)**

[Effects of amrinone on hemodynamics, oxygen consumption and plasma catecholamine levels in anesthetized dogs] Kosugi I, et al. **Masui** 1985 Apr;34(4):429–33 (Eng. Abstr.) **(Jpn)**

[A comparative study on the effect of vagotomy and splanchnicectomy on the catecholamine content of the stomach, duodenum and pancreas]

Hamaji M, et al. **Nippon Shokakibyo Gakkai Zasshi** 1985 Apr; 82(4):587–91 (Eng. Abstr.) **(Jpn)**

[Levels of catecholamines in the hypothalamus, hypophysis and in the adrenal in sheep after whole–body exposure to gamma rays] Pástorová B, et al. **Vet Med (Praha)** 1985 Aug;30(8):485–92 (Eng. Abstr.) **(Slo)**

[Distribution of catecholamines and monoamine oxidase activity in the system controlling sexual function in sheep] Pástorová B, et al. **Vet Med (Praha)** 1985 Sep;30(9):563–70 (Eng. Abstr.) **(Slo)**

[Correlation between clinical and laboratory data in depression. Therapeutic orientation by means of vitamins and amino acids] Mesones HL, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):25–36 (Eng. Abstr.) **(Spa)**

CENTRAL NERVOUS SYSTEM AGENTS

Different effects of centrally acting drugs on rabbit platelet aggregation: with special reference to selective inhibitory effects of antipsychotics and antidepressants. Ishigooka J, et al. **Biol Psychiatry** 1985 Aug; 20(8):866–73

CHILD BEHAVIOR

Attention deficit disorder children with or without hyperactivity. Which behaviors are helped by stimulants? Ullmann RK, et al. **Clin Pediatr (Phila)** 1985 Oct;24(10):547–51

CHILD BEHAVIOR DISORDERS

Developmental manifestations in a boy with prepubertal bipolar disorder. Reiss AL. **J Clin Psychiatry** 1985 Oct;46(10):441–3

Successful nicotinamide treatment in an autosomal dominant behavioral and psychiatric disorder. Blom W, et al. **J Inherited Metab Dis** 1985; 8 Suppl 2:107–8

CHILD PSYCHIATRY

Evaluating attitudes of child psychiatry residents to psychotropic medication: implications for training. Schachar RJ. **Can J Psychiatry** 1985 Aug;30(5):348–52

CHLORAMINES

Removal of sodium channel inactivation in squid axon by the oxidant chloramine–T. Wang GK, et al. **J Gen Physiol** 1985 Aug; 86(2):289–302

[Comparative sensitivity of microorganisms to monochloramine B] Krucheniuk TB. **Gig Sanit** 1985 Jun;(6):75–7 **(Rus)**

[Gram–negative conditionally pathogenic microflora in hospitals and its resistance to chloramine] Trukhina GM, et al. **Gig Sanit** 1985 May; (5):82–4 **(Rus)**

CHLORDIAZEPOXIDE

No cross–tolerance between the stimulatory and depressant actions of benzodiazepines in mice. File SE, et al. **Behav Brain Res** 1985 Sep; 17(1):1–7

Correlation of [3H]diazepam binding density with anxiolytic locus in the amygdaloid complex of the rat. Thomas SR, et al. **Brain Res** 1985 Sep 2;342(1):85–90

Chlordiazepoxide–induced hyperphagia in non–food–deprived rats: effects of Ro15–1788, CGS 8216 and ZK 93 426. Cooper SJ, et al. **Eur J Pharmacol** 1985 May 28;112(1):39–45

Chlordiazepoxide and successive discrimination: different effects on acquisition and performance. McNaughton N. **Pharmacol Biochem Behav** 1985 Sep;23(3):487–94

Associative control of tolerance to the sedative and hypothermic effects of chlordiazepoxide. Greeley J, et al. **Psychopharmacology (Berlin)** 1985; 86(4):487–93

Maternal aggression in rats: effects of chlordiazepoxide and fluprazine. Olivier B, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):68–76

Comparison between the effects of propranolol and chlordiazepoxide on timing behaviour in the rat. Salmon P, et al. **Psychopharmacology (Berlin)** 1985;87(2):219–24

[Pharmacology in automobile driving and medical practice. II. Euhypnotic effect of Elenium and psychomotor efficiency in humans] Gałuszko P, et al. **Psychiatr Pol** 1984 Nov–Dec;18(6):555–60 (Eng. Abstr.) **(Pol)**

P-CHLOROPHENYLALANINE

Maternal aggression in mice: effects of treatments with PCPA, 5-HTP and 5–HT receptor antagonists. Ieni JR, et al. **Eur J Pharmacol** 1985 May 8;111(2):211–20

Pharmacological studies on the serotoninergic and nonserotonin–mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L–tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283–8

Evidence of norepinephrine–mediated suppression of para–chlorophenylalanine–induced muricidal behavior. Pucilowski O, et al. **Pharmacol Res Commun** 1985 May;17(5):457–62

CHLORPROMAZINE

The susceptibility of Plasmodium falciparum in vitro to chlorpromazine and the stereo–isomeric compounds cis(Z)– and trans(E)–clopenthixol. Kristiansen JE, et al. **Acta Pathol Microbiol Immunol Scand [B]** 1985 Jun;93(3):249–51

Plasma protein binding of salicylic acid, phenytoin, chlorpromazine, propranolol and pethidine using equilibrium dialysis and ultracentrifugation. Verbeeck RK, et al. **Arzneimittelforschung** 1985; 35(6):903–6

Generation of electronically excited species during enzymatic oxidation of chlorpromazine and related compound. Nakano M, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):952–6

Chlorpromazine—a specific effect on breathlessness? O'Neill PA, et al. **Br J Clin Pharmacol** 1985 Jun;19(6):793–7

Cross–tolerance to the hypothermic effect of delta 8–tetrahydrocannabinol 11–hydroxy–delta 8–tetrahydrocannabinol and chlorpromazine in the mouse. Yamamoto I, et al. **Eur J Pharmacol** 1985 May 8; 111(2):159–66

The effects of chlorpromazine and imipramine on rate and stimulus control of matching to sample. Newland MC, et al. **J Exp Anal Behav** 1985 Jul;44(1):49–68

The effect of sample storage on the stability of chlorpromazine in plasma and whole blood. McKay G, et al. **J Pharmacol Methods** 1984 Oct; 12(3):221–3

Effects of triethyltin and its interaction with d–amphetamine and chlorpromazine on responding under a multiple schedule of food presentation in rats. Rastogi SK, et al. **Neurobehav Toxicol Teratol** 1985 May–Jun;7(3):239–42

Ultrastructure of nerve tissue on experimental brain injuries in animals with increased immunobiological reactivity of the body on action of some desensitizing preparations. Sukhorukova LI. **Neurosci Behav Physiol** 1985 Mar–Apr;15(2):93–7

A conveyor belt task for assessing visuo–motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d–amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):125–31

Influence of housing conditions and state of partner on conditioning and extinction of taste aversion to lithium and chlorpromazine. Giardini V. **Psychopharmacology (Berlin)** 1985;86(1–2):96–101

Therapeutic monitoring of chlorpromazine I: Pitfalls in plasma analysis. Hubbard JW, et al. **Ther Drug Monit** 1985;7(2):222–8

CHLORPROTHIXENE

Phenolic metabolites of chlorprothixene in man and dog. Breyer–Pfaff U, et al. **Drug Metab Dispos** 1985 Jul–Aug;13(4):479–89

CHOICE BEHAVIOR

Benzodiazepines reduce the tolerance to reward delay in rats. Thiébot MH, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):147–52

CLOMIPRAMINE

A double-blind group comparison of mianserin and clomipramine in the treatment of mildly depressed psychiatric out-patients. Dunbar GC, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:60–6

Clomipramine treatment of childhood obsessive-compulsive disorder. A double-blind controlled study. Flament MF, et al. **Arch Gen Psychiatry** 1985 Oct;42(10):977–83

Superfusion of clomipramine within the ventromedial hypothalamus selectively suppresses paradoxical sleep in freely moving rats. Danguir J, et al. **Brain Res Bull** 1985 Jul;15(1):1–4

Severe depression treatment: experience using maprotiline (Ludiomil) in combination with clomipramine (Anafranil). Ovuga E. **East Afr Med J** 1985 Feb;62(2):79–81

Determination of citalopram, amitriptyline and clomipramine in plasma by reversed-phase high-performance liquid chromatography. Rop PP, et al. **J Chromatogr** 1985 Feb 27;338(1):171–8

Efficacy and tolerability of sustained-release clomipramine (Anafranil SR) in the treatment of phobias: a comparison with the conventional formulation of clomipramine (Anafranil). Allsopp LF, et al. **J Int Med Res** 1985;13(4):203–8

Changes in human platelet 5 HT level after 1 week of chlorimipramine treatment. Poirier MF, et al. **Psychopharmacology (Berlin)** 1985; 86(1–2):194–6

[Measurement of basal plasma levels of 3 anterior pituitary hormones during acute or chronic treatment with tricyclic antidepressants] Goyot C, et al. **Encephale** 1985 Mar–Apr;11(2):45–51 (Eng. Abstr.) **(Fre)**

COCAINE

Effect of cocaine dependence on plasma phenylalanine and tyrosine levels and on urinary MHPG excretion. Tennant FS Jr. **Am J Psychiatry** 1985 Oct;142(10):1200–1

Propranolol-induced hypertension in treatment of cocaine intoxication. Ramoska E, et al. **Ann Emerg Med** 1985 Nov;14(11):1112–3

Electrochemistry of norcocaine nitroxide and related compounds: implications for cocaine hepatotoxicity. Charkoudian JC, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1044–51

Sodium-independent binding of [3H]cocaine in mouse striatum is serotonin related. Reith ME, et al. **Brain Res** 1985 Sep 2;342(1):145–8

The rising popularity of cocaine: how serious a problem? Katz S. **Can Med Assoc J** 1985 Oct 1;133(7):682–5

Kinetics of cocaine distribution, elimination, and chronotropic effects. Chow MJ, et al. **Clin Pharmacol Ther** 1985 Sep;38(3):318–24

Treatment of chronic cocaine abuse and attention deficit disorder, residual type, with magnesium pemoline. Weiss RD, et al. **Drug Alcohol Depend** 1985 May;15(1–2):69–72

Comparison of fixed-ratio and progressive-ratio schedules of maintenance of stimulant drug-reinforced responding. Winger G, et al. **Drug Alcohol Depend** 1985 May;15(1–2):123–30

Histopathology of the spinal cord after intrathecal cocaine, bupivacaine, lignocaine and adrenaline in the rat. Bahar M, et al. **Eur J Anaesthesiol** 1984 Sep;1(3):293–7

Factors which differentiate cocaine users in treatment from nontreatment users. Chitwood DD, et al. **Int J Addict** 1985 Mar;20(3):449–59

Classics revisited. Uber Coca. By Sigmund Freud. **J Subst Abuse Treat** 1984;1(3):206–17

The Fair Oaks Hospital cocaine treatment program. Annitto WJ, et al. **J Subst Abuse Treat** 1984;1(3):223–6

Status of cocaine abuse 1984. Dougherty RJ. **J Subst Abuse Treat** 1984; 1(3):157–61

Methylphenidate (Ritalin) treatment of cocaine dependence--a preliminary report. Khantzian EJ, et al. **J Subst Abuse Treat** 1984; 1(2):107–12

Involvement of dopamine in the aversive stimulus properties of cocaine in rats. Hunt T, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):945–8

Cathinone, cocaine and methamphetamine: similarity of behavioral effects. Schechter MD, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):913–6

Cocaine: excitatory effects on sensorimotor reactivity measured with acoustic startle. Davis M. **Psychopharmacology (Berlin)** 1985; 86(1–2):31–6

Information processing components of the auditory event related potential are reduced by cocaine. Herning RI, et al. **Psychopharmacology (Berlin)** 1985;87(2):178–85

Self-administration of low-dose cocaine by rats at reduced and recovered body weight. Papasava M, et al. **Psychopharmacology (Berlin)** 1985; 85(4):419–25

Cocaine blocks the dopamine depletion induced by MPTP. Mayer RA, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jul;49(1):145–8

COGNITION

Hyperactive children treated with stimulants. Is cognitive training a useful adjunct? Abikoff H, et al. **Arch Gen Psychiatry** 1985 Oct; 42(10):953–61

Delineation of pharmacopsychological effects by means of endogenous event-related brain potentials: an exemplification with flupentixol. Rösler F, et al. **Neuropsychobiology** 1985;13(1–2):81–92

Information processing components of the auditory event related potential are reduced by cocaine. Herning RI, et al. **Psychopharmacology (Berlin)** 1985;87(2):178–85

Cognitive effects of lithium treatment in normal volunteers. Weingartner H, et al. **Psychopharmacology (Berlin)** 1985;86(4):472–4

COGNITION DISORDERS

[Effect of diazepam on interference processes] Vinitskiĭ IM, et al. **Farmakol Toksikol** 1985 Jul–Aug;48(4):38–41 (Eng. Abstr.) **(Rus)**

CONDITIONING (PSYCHOLOGY)

Effects of phenobarbital, clonazepam, valproic acid, ethosuximide, and phenytoin on the delayed matching-to-sample performance of pigeons. Picker M, et al. **Psychopharmacology (Berlin)** 1985;86(4):494–8

CONDITIONING, CLASSICAL

Relationship between the release and uptake of noradrenaline by rat brain synaptosomes in the formation of defensive conditioned reflex. Bazyan AS, et al. **Acta Neurobiol Exp (Warsz)** 1985;45(1–2):37–46

Role of ethanol in conditioning aversion to alcoholic beverages in rats. Franchina JJ, et al. **Behav Res Ther** 1985;23(5):521–9

The conditioned place preference is affected by two independent reinforcement processes. White NM, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):37–42

Influence of housing conditions and state of partner on conditioning and extinction of taste aversion to lithium and chlorpromazine. Giardini V. **Psychopharmacology (Berlin)** 1985;86(1–2):96–101

[Effect of insulin and its polymeric analogs on learning and memory processes in the rabbit] Bakharev VD, et al. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):314–21 (Eng. Abstr.) **(Rus)**

[Effect of a cyclic analog of enkephalin on learning and memory in the mouse] Getsova VM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug; 35(4):710–7 (Eng. Abstr.) **(Rus)**

[Effect of noradrenaline, microapplied to the dorsal hippocampus of the rat, on conditioned reflex memory] Melikov EM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):780–2 **(Rus)**

[Formation and extinction of drinking conditioned reflexes after unilateral intercollicular sectioning of the brain in the rat] Shabanov PD, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):777–9 **(Rus)**

CONDITIONING, OPERANT

The effects of chlorpromazine and imipramine on rate and stimulus control of matching to sample. Newland MC, et al. **J Exp Anal Behav** 1985 Jul;44(1):49–68

Comparisons between discrete lever-press and shuttle avoidance responses in mice: acquisition processes and effects of psychoactive drugs. Kuribara H, et al. **Jpn J Pharmacol** 1985 Jun;38(2):141–51

Comparative effects of cathinone and amphetamine on fixed-interval operant responding: a rate-dependency analysis. Goudie AJ. **Pharmacol Biochem Behav** 1985 Sep;23(3):355–65

Involvement of dopamine in the aversive stimulus properties of cocaine in rats. Hunt T, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):945–8

Asymmetrical effect of unilateral cortical lesions and amphetamine on DRL-20: a time-loss analysis. Kubos KL, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):1001–6

Norepinephrine-facilitated eating: reduction in saccharin preference and conditioned flavor preferences with increase in quinine aversion. Matthews JW, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):1045–52

Rate-dependency and hyperactivity: methylphenidate effects on operant responding. Rapport MD, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):77–83

Opposing acute and chronic behavioural effects of a beta-blocker, propranolol, in the rat. Salmon P, et al. **Psychopharmacology (Berlin)** 1985;86(4):480–6

[Development of passivity in the rat: effect of tranquilizers and antidepressants] Khonicheva NM, et al. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):339–47 (Eng. Abstr.) **(Rus)**

[Functional differentiation of the theta-rhythm of the hippocampus in the cat] Melikov EM. **Zh Vyssh Nerv Deiat** 1985 May–Jun; 35(3):457–64 (Eng. Abstr.) **(Rus)**

CONFLICT (PSYCHOLOGY)

Mechanisms of the initial treatment phenomenon to diazepam in the rat. Mokler DJ, et al. **Psychopharmacology (Berlin)** 1985;87(2):242–6

[Effect of the antioxidant dibunol and its combination with phenazepam on the behavior of rats in a conflict situation] Molodavkin GM, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):36–8 (Eng. Abstr.) **(Rus)**

CORTICOSTERONE

Monoamines and the effect of ethanol on corticosterone and non-esterified fatty acids. Brick J, et al. **Alcohol** 1985 Mar-Apr;2(2):261-5

Effect of exogenous ACTH on serum corticosterone and cortisol concentrations in the Moluccan cockatoo (Cacatua moluccensis). Walsh MT, et al. **Am J Vet Res** 1985 Jul;46(7):1584-8

Down-regulation of neural corticosterone receptors by corticosterone and dexamethasone. Sapolsky RM, et al. **Brain Res** 1985 Jul 22; 339(1):161-5

Sexual dimorphism of glucocorticoid binding in rat brain. Turner BB, et al. **Brain Res** 1985 Sep 16;343(1):16-23

Increased serum corticosterone levels in triorthotolyl phosphate-treated chickens. Foil L, et al. **Bull Environ Contam Toxicol** 1985 Jun; 34(6):780-6

The effect of chronic saline exposure on the electrolyte balance, nitrogen metabolism, and corticosterone titer in the American alligator, Alligator mississippiensis. Laurén DJ. **Comp Biochem Physiol** [A] 1985; 81(2):217-23

Plasma concentrations of arginine vasotocin, prolactin, aldosterone and corticosterone in relation to oviposition and dietary NaCl in the domestic fowl. Rice GE, et al. **Comp Biochem Physiol** [A] 1985; 81(4):769-77

Effect of hypophysectomy on plasma electrolytes and adrenal mineralocorticoid secretion in the terrestrial chelonian Testudo hermanni. Vallarino M, et al. **Comp Biochem Physiol** [A] 1985; 81(2):283-6

Changes in plasma levels of cortisol and corticosterone after acute ACTH stimulation in rusa deer (Cervus rusa timorensis). van Mourik S, et al. **Comp Biochem Physiol** [A] 1985;81(3):545-9

Adrenergic stimulation of adrenocortical secretion in immature fowl. Rees A, et al. **Comp Biochem Physiol** [C] 1985;81(2):387-9

Properties of binding of partially purified glucocorticoid receptor from rat liver with glucocorticoids of different biopotencies. Izawa M, et al. **Endocrinol Jpn** 1985 Jun;32(3):385-97

Protein utilization in growth: effect of lysine deficiency on serum growth hormone, somatomedins, insulin, total thyroxine (T4) and triiodothyronine, free T4 index, and total corticosterone. Cree TC, et al. **Endocrinology** 1985 Aug;117(2):667-73

The central vs. peripheral effects of clonidine on ACTH, corticosterone and glucose release. Smythe GA, et al. **Eur J Pharmacol** 1985 May 20;111(3):401-3

The lack of effect of electrochemical stimulation of the hypothalamus and median eminence on the plasma corticosterone level after lesion of the paraventricular nuclei. Lengvári I, et al. **Exp Clin Endocrinol** 1985 Jun;85(3):314-8

Adrenocortical hormones and brain growth: reversibility and differential sensitivity during development. Devenport LD, et al. **Exp Neurol** 1985 Oct;90(1):44-52

Adrenocortical metabolism and plasma corticosterone in soman intoxicated rabbits. Doebler JA, et al. **Experientia** 1985 Sep 15; 41(9):1145-7

Effects of continuous treatment with synthetic ACTH1-24 or corticosterone on immature Gallus domesticus. Davison TF, et al. **Gen Comp Endocrinol** 1985 Sep;59(3):416-23

Factors affecting the secretory dynamics of 1 alpha-hydroxycorticosterone in the dogfish, Scyliorhinus canicula. Hazon N, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):50-5

Corticosterone and aldosterone dose-dependent responses to ACTH and angiotensin II in the duck (Anas platyrnynchos). Klingbeil CK. **Gen Comp Endocrinol** 1985 Sep;59(3):382-90

Transitory corticosterone responses of ducks (Anas platyrhynchos) to exercise. Rees A, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):100-4

Effects of corticosterone and 5 alpha-dihydrocorticosterone on brain excitability in the rat. Dubrovsky B, et al. **J Neurosci Res** 1985; 14(1):117-28

Effect of calcium on corticosteroid secretion by isolated frog interrenal gland. Lihrmann I, et al. **J Steroid Biochem** 1985 Aug;23(2):169-75

Effect of somatostatin on the zona glomerulosa of rats treated with angiotensin II or captopril: stereology and plasma hormone concentrations. Mazzocchi G, et al. **J Steroid Biochem** 1985 Sep; 23(3):353-6

Plasma cortisol and corticosterone concentrations in the golden hamster, (Mesocricetus auratus). Ottenweller JE, et al. **Life Sci** 1985 Oct 21; 37(16):1551-8

Delta-sleep-inducing peptide reduces CRF-induced corticosterone release. Graf MV, et al. **Neuroendocrinology** 1985 Oct;41(4):353-6

Simultaneous determination of blood levels of corticosterone and growth hormone in the male rat: relation to sleep-wakefulness cycle. Mitsugi N, et al. **Neuroendocrinology** 1985 Aug;41(2):125-30

Pharmacological studies on the serotoninergic and nonserotonin-mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L-tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283-8

Modifications of adrenocortical responses following frontal cortex simulation in rats with hypothalamic deafferentations and medial forebrain bundle lesions. Feldman S, et al. **Neuroscience** 1985 Aug; 15(4):1045-7

Extraction of corticosterone from cell homogenates and subcellular fractions of the rat adrenal cortex. II. ACTH-induced changes in subcellular corticosterone. Mathew JK, et al. **Steroids** 1984 Aug; 44(2):105-22

[Effects of different acute and chronic stresses on general growth and adrenal cortex activity in rats] el Feki A, et al. **Ann Endocrinol (Paris)** 1985;46(2):107-12 (Eng. Abstr.) **(Fre)**

[The effect of bradykinin on free nitrogen compounds and energy production in the rat brain] Hashimoto Y, et al. **Shikwa Gakuho** 1985 Mar;85(3):371-9 (Eng. Abstr.) **(Jpn)**

[ACTH, corticosterone and beta-endorphin in the blood plasma of rats under prolonged immobilization stress] Kiiatkin EA, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):157-60 (Eng. Abstr.) **(Rus)**

[Receptor binding of corticosterone in various structures of the rat brain after neonatal blockade of the hypophyseal-adrenal system] Garina IA, et al. **Probl Endokrinol (Mosk)** 1985 Jul-Aug;31(4):46-9 (Eng. Abstr.) **(Rus)**

[Plasma lipoprotein absorption by steroid-producing organs in the rat] Poliakov LM, et al. **Probl Endokrinol (Mosk)** 1985 Jul-Aug; 31(4):72-5 (Eng. Abstr.) **(Rus)**

CORTICOTROPIN

Cell types of the pars distalis of the hedgehog (Erinaceus europaeus L.) adenohypophysis: cytological, immunocytochemical and ultrastructural studies. 3. Opiocorticomelanotropic cells. Girod C, et al. **Acta Anat (Basel)** 1985;123(1):67-71

Propranolol inhibits the maturational effect of adrenocorticotropin in the fetal sheep lung. Vilos GA, et al. **Am J Obstet Gynecol** 1985 Oct 15; 153(4):472-7

Diurnal-stimulated and stress-induced ACTH release in rats is mediated by ventral noradrenergic bundle. Szafarczyk A, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):E219-26

Effect of exogenous ACTH on serum corticosterone and cortisol concentrations in the Moluccan cockatoo (Cacatua moluccensis). Walsh MT, et al. **Am J Vet Res** 1985 Jul;46(7):1584-8

Proopiomelanocortin-derived peptides in the immune system. Blalock JE. **Clin Endocrinol** (Oxf) 1985 Jun;22(6):823-7 (15 ref.)

Augmentation of the response to CRF in man: relative contributions of endogenous angiotensin and vasopressin. Milsom SR, et al. **Clin Endocrinol (Oxf)** 1985 May;22(5):623-9

Changes in plasma levels of cortisol and corticosterone after acute ACTH stimulation in rusa deer (Cervus rusa timorensis). van Mourik S, et al. **Comp Biochem Physiol** [A] 1985;81(3):545-9

Corticotrope response to removal of releasing factors and corticosteroids in vivo. Dallman MF, et al. **Endocrinology** 1985 Nov;117(5):2190-7

The effect of various corticotropin-releasing factor trains on the release of adrenocorticotropin, beta-endorphin, and beta-lipotropin from perifused ovine pituitary cells. Evans MJ, et al. **Endocrinology** 1985 Sep;117(3):893-9

Direct effects of adrenocorticotropic hormone on bovine adrenomedullary cells: adenosine 3',5'-monophosphate-dependent phosphorylation of tyrosine hydroxylase. Michener ML, et al. **Endocrinology** 1985 Aug; 117(2):730-7

The effects of growth hormone, prolactin, corticotropin, and thyrotropin on the production and secretion of somatostatin by hypothalamic cells in vitro. Robbins RJ, et al. **Endocrinology** 1985 Aug;117(2):538-43

The central vs. peripheral effects of clonidine on ACTH, corticosterone and glucose release. Smythe GA, et al. **Eur J Pharmacol** 1985 May 20;111(3):401-3

beta-Endorphin and ACTH related peptides in primary cultures of rat anterior pituitary cells: evidence for different intracellular pools. Ham J, et al. **FEBS Lett** 1985 Oct 14;190(2):253-8

Effects of continuous treatment with synthetic ACTH1-24 or corticosterone on immature Gallus domesticus. Davison TF, et al. **Gen Comp Endocrinol** 1985 Sep;59(3):416-23

Corticosterone and aldosterone dose-dependent responses to ACTH and angiotensin II in the duck (Anas platyrhynchos). Klingbeil CK. **Gen Comp Endocrinol** 1985 Sep;59(3):382-90

Thyroid function in adult rough-skinned newts (Taricha granulosa): effects of hypophysectomy and hormone replacement. Specker JL, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):326-31

Investigation of beta-endorphin and adrenocorticotropic hormone in placenta, amniotic membrane and umbilical cord using an immunoperoxidase technique. Reinthaller A, et al. **Gynecol Obstet Invest** 1985;19(3):135-8

Plasma ACTH, cortisol and aldosterone concentrations in chronically cannulated ovine fetuses and in lambs injected with ovine corticotropin releasing factor. Pradier P, et al. **J Dev Physiol** 1985 Aug; 7(4):259-68

Salmonid melanin-concentrating hormone inhibits corticotrophin release. Baker BI, et al. **J Endocrinol** 1985 Aug;106(2):R5-8

Effect of imipramine and adrenocorticotropin administration on the rat brain norepinephrine-coupled cyclic nucleotide generating system:

alterations in alpha and beta adrenergic components. Duman RS, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):409–14

Calmodulin inhibitors decrease the CRF–and AVP–induced ACTH release in vitro: interaction of calcium–calmodulin and the cyclic AMP system. Murakami K, et al. **Neuroendocrinology** 1985 Jul;41(1):7–12

Early visual information processing in depressive patients treated with ORG 2766 (an ACTH 4–9 analogue). d'Elia G, et al. **Neuropsychobiology** 1985;13(1–2):63–8

Regulation of adrenocorticotropin release from the anterior pituitary. Reisine T. **Psychopharmacol Bull** 1985;21(3):438–42

Extraction of corticosterone from cell homogenates and subcellular fractions of the rat adrenal cortex. II. ACTH–induced changes in subcellular corticosterone. Mathew JK, et al. **Steroids** 1984 Aug; 44(2):105–22

[ACTH, corticosterone and beta–endorphin in the blood plasma of rats under prolonged immobilization stress] Kiiatkin EA, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):157–60 (Eng. Abstr.) **(Rus)**

[Effect of ACTH on the corticosteroid and progesterone levels in female hamadryas baboons in relation to the menstrual cycle phase] Todua TN, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):135–7 (Eng. Abstr.) **(Rus)**

CORTICOTROPIN RELEASING HORMONE

The distribution of immunoreactive corticotrophin–releasing factor in the human pituitary stalk. Coates PJ. **Acta Endocrinol (Copenh)** 1985 Aug; 109(4):433–9

Stability of rat (human) corticotropin–releasing factor in serum, urine and tissue incubation medium. Hashimoto K, et al. **Acta Med Okayama** 1985 Jun;39(3):199–206

Cholecystokinin in the medial parvocellular subdivision of the paraventricular nucleus. Co–existence with corticotropin–releasing hormone. Mezey E, et al. **Ann NY Acad Sci** 1985;448:152–6

CRF–containing neurons of the rat hypothalamus. Daikoku S, et al. **Cell Tissue Res** 1985;240(3):575–84

Augmentation of the response to CRF in man: relative contributions of endogenous angiotensin and vasopressin. Milsom SR, et al. **Clin Endocrinol (Oxf)** 1985 May;22(5):623–9

Conspectus. Corticotropin–releasing factor. DeSouza EB. **Compr Ther** 1985 Jun;11(6):3–5

Corticotropin–releasing factor: its action on the islets of Langerhans. Moltz JH, et al. **Endocr Res** 1985;11(1–2):87–93

Corticotrope response to removal of releasing factors and corticosteroids in vivo. Dallman MF, et al. **Endocrinology** 1985 Nov;117(5):2190–7

The effect of various corticotropin–releasing factor trains on the release of adrenocorticotropin, beta–endorphin, and beta–lipotropin from perifused ovine pituitary cells. Evans MJ, et al. **Endocrinology** 1985 Sep;117(3):893–9

Effects of adrenalectomy and dexamethasone administration on the level of prepro–corticotropin–releasing factor messenger ribonucleic acid (mRNA) in the hypothalamus and adrenocorticotropin/beta–lipotropin precursor mRNA in the pituitary in rats. Jingami H, et al. **Endocrinology** 1985 Oct;117(4):1314–20

Evidence for local corticotropin releasing factor (CRF)–immunoreactive neuronal circuits in the paraventricular nucleus of the rat hypothalamus. An electron microscopic immunohistochemical analysis. Liposits Z, et al. **Histochemistry** 1985;83(1):5–16 (59 ref.)

Plasma ACTH, cortisol and aldosterone concentrations in chronically cannulated ovine fetuses and in lambs injected with ovine corticotropin releasing factor. Pradier P, et al. **J Dev Physiol** 1985 Aug; 7(4):259–68

Gastrointestinal secretory, motor and circulatory effects of corticotropin releasing factor (CRF). Konturek SJ, et al. **Life Sci** 1985 Sep 30; 37(13):1231–40

In vitro study of immunoreactive corticotropin–releasing factor release from the rat hypothalamus. Suda T, et al. **Life Sci** 1985 Oct 21; 37(16):1499–505

Co–localization of corticotropin–releasing factor and vasopressin in median eminence neurosecretory vesicles. Whitnall MH, et al. **Nature** 1985 Sep 19–25;317(6034):248–50

Delta–sleep–inducing peptide reduces CRF–induced corticosterone release. Graf MV, et al. **Neuroendocrinology** 1985 Oct;41(4):353–6

Calmodulin inhibitors decrease the CRF–and AVP–induced ACTH release in vitro: interaction of calcium–calmodulin and the cyclic AMP system. Murakami K, et al. **Neuroendocrinology** 1985 Jul;41(1):7–12

Effects of intracerebroventricular administration of ovine corticotropin–releasing factor (CRF 1–41) on passive avoidance behaviour: lack of influence on monoamine contents of limbic brain areas. Fekete M, et al. **Neuropeptides** 1985 Jul;6(4):283–292

Corticotropin releasing factor–like immunoreactivity in sensory ganglia and capsaicin sensitive neurons of the rat central nervous system: colocalization with other neuropeptides. Skofitsch G, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):307–18

Distribution of corticotropin releasing factor–like immunoreactivity in the rat brain by immunohistochemistry and radioimmunoassay: comparison and characterization of ovine and rat/human CRF antisera. Skofitsch G, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):319–36

CULTURE

Cultural phenomenology and residency training revisited: a personal account. Zimmer B. **Int J Soc Psychiatry** 1985 Autumn;31(3):188–93

DANSYL COMPOUNDS

Internalization of cycloheptaamylose–dansyl chloride complex during labelling of surface membrane in living Paramecium aurelia cells. Giordano PA, et al. **Basic Appl Histochem** 1985;29(2):121–33

Introduction of the dansyl group into histidine and tyrosine residues in peptides and proteins. Buchta R, et al. **Biochem Biophys Res Commun** 1985 Jul 16;130(1):350–7

Cellular uptake and localization of fluorescent derivatives of phorbol ester tumor promoters. Liskamp RM, et al. **Biochem Biophys Res Commun** 1985 Sep 16;131(2):920–7

Lactose repressor protein modified with dansyl chloride: activity effects and fluorescence properties. Hsieh WT, et al. **Biochemistry** 1985 Jun 4;24(12):3043–9

DELUSIONS

A 'gratuitous' conclusion on ECT [letter] Fink M. **Am J Psychiatry** 1985 Sep;142(9):1129–30

Nortriptyline in the treatment of a monosymptomatic delusion [letter] Pylko T, et al. **Am J Psychiatry** 1985 Oct;142(10):1223

Dysmorphophobia and monosymptomatic hypochondriasis [letter] Thomas CS. **Am J Psychiatry** 1985 Sep;142(9):1121

Higher CSF levels of HVA and 5–HIAA in delusional compared to nondelusional depression [letter] Aberg–Wistedt A, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):925–6

DEMENTIA

Involutional dementias: new perspectives. Borromei A, et al. **Ital J Neurol Sci** 1985 Jun;6(2):167–71

DEPRESSION

Separate and combined anxiolytic and anti–depressant treatment of mixed anxiety/depression. A double–blind, placebo controlled comparison. Sussex Clinical Trials Group. **Acta Psychiatr Scand** 1985 Jul; 72(1):81–8

A double–blind group comparison of mianserin and clomipramine in the treatment of mildly depressed psychiatric out–patients. Dunbar GC, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:60–6

The present status of monoamine oxidase inhibitors. Pare CM. **Br J Psychiatry** 1985 Jun;146:576–84 (88 ref.)

A monoamine oxidase inhibitor reverses the 'separation syndrome' in a new hamster separation model of depression. Crawley JN. **Eur J Pharmacol** 1985 May 28;112(1):129–33

Electro–acupuncture vs. amitriptyline in the treatment of depressive states. Luo HC, et al. **J Tradit Chin Med** 1985 Mar;5(1):3–8

[Questionnaires for anxiety and depression] Harlay A. **Infirm Fr** 1985 Apr; (264):15–22 **(Fre)**

[Clinical experiences with the new–generation anxiolytic agent cloxazolam—a double–blind study] Zmorski T, et al. **Schweiz Rundsch Med Prax** 1985 Jul 2;74(27):728–34 (Eng. Abstr.) **(Ger)**

DEPRESSIVE DISORDER

Long–term lithium prophylaxis in recurrent unipolar depression. A controversial indication? Lepkifker E, et al. **Acta Psychiatr Belg** 1985 May–Jun;85(3):434–43

Citalopram versus mianserin. A controlled, double–blind trial in depressed patients. de Wilde J, et al. **Acta Psychiatr Scand** 1985 Jul; 72(1):89–96

Double–blind comparison between a serotonin and a noradrenaline reuptake blocker in the treatment of depressed outpatients. Clinical aspects. Nyström C, et al. **Acta Psychiatr Scand** 1985 Jul;72(1):6–15

Relationship of free nortriptyline levels to therapeutic response. Perry PJ, et al. **Acta Psychiatr Scand** 1985 Aug;72(2):120–5

New implications of antidepressant therapy in neuropsychopharmacology: focus on mianserin. 14th Congress of the Collegium Internationale Neuro–Psychopharmacologicum. Florence, Italy, 19–23 June 1984. **Acta Psychiatr Scand [Suppl]** 1985;320:1–105

Interaction of biologic and psychologic factors in the origin of depressive disorders. Akiskal HS. **Acta Psychiatr Scand [Suppl]** 1985;319:131–9

Treatment of childhood and adolescent depression with mianserin. Dugas M, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:48–53

Depression and anxiety: mianserin and nomifensine compared in a double–blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67–74

Mianserin is better tolerated and more effective in depression than a nomifensine–clobazam combination: a double–blind study. Levin A, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:75–80

Changes in sleep EEG architecture during the treatment of depressed patients with mianserin. Mendlewicz J, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:26-9

Profiles of antidepressant activity with the Montgomery-Asberg Depression Rating Scale. Montgomery SA, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:38-42

Approach to chronic and treatment-resistant depressions. Akiskal HS. **Adv Biochem Psychopharmacol** 1985;40:159-63

Maintenance treatment of recurrent unipolar depression: pharmacology and psychotherapy. Frank E, et al. **Adv Biochem Psychopharmacol** 1985; 40:139-51

Research overview of drug therapy in recurrent and chronic depression. Prien RF. **Adv Biochem Psychopharmacol** 1985;40:121-30

Practical problems of lithium maintenance treatment. Schou M. **Adv Biochem Psychopharmacol** 1985;40:131-8

Recognition of pseudodementia. McAllister TW. **Am Fam Physician** 1985 Oct;32(4):175-81

A 'gratuitous' conclusion on ECT [letter] Fink M. **Am J Psychiatry** 1985 Sep;142(9):1129-30

Serial ECG measurements at controlled plasma levels of nortriptyline in depressed children. Geller B, et al. **Am J Psychiatry** 1985 Sep; 142(9):1095-7

A lithium-tricyclic combination for treatment of depression [letter] Pande AD, et al. **Am J Psychiatry** 1985 Oct;142(10):1228-9

Subjective memory complaints in geriatric depression. Plotkin DA, et al. **Am J Psychiatry** 1985 Sep;142(9):1103-5

Overview: toward a dysregulation hypothesis of depression. Siever LJ, et al. **Am J Psychiatry** 1985 Sep;142(9):1017-31 (134 ref.)

Higher CSF levels of HVA and 5-HIAA in delusional compared to nondelusional depression [letter] Aberg-Wistedt A, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):925-6

Alprazolam as an antidepressant [letter] Empson P. **Aust NZ J Psychiatry** 1985 Jun;19(2):197

CSF substance P immunoreactivity in affective disorders. Berrettini WH, et al. **Biol Psychiatry** 1985 Sep;20(9):965-70

Rapid antidepressant activity of destyr gamma endorphin: correlation with urinary melatonin. Chazot G, et al. **Biol Psychiatry** 1985 Sep; 20(9):1026-30

MHPG, ECT, and depression [letter] McDougle CJ, et al. **Biol Psychiatry** 1985 Aug;20(8):927

A comparison of the acute effects of dextroamphetamine and fenfluramine in depression. Ward NG, et al. **Biol Psychiatry** 1985 Oct; 20(10):1090-7

Plasma concentrations of nortriptyline and its 10-hydroxy metabolite in depressed patients--relationship to the debrisoquine hydroxylation metabolic ratio. Nordin C, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):832-5

An evaluation of alprazolam in the treatment of reactive or neurotic (secondary) depression. Imlah NW. **Br J Psychiatry** 1985 May; 146:515-9

The present status of monoamine oxidase inhibitors. Pare CM. **Br J Psychiatry** 1985 Jun;146:576-84 (88 ref.)

Depression in general practice: case thresholds and diagnosis. Sireling LI, et al. **Br J Psychiatry** 1985 Aug;147:113-9

Depression in general practice: clinical features and comparison with out-patients. Sireling LI, et al. **Br J Psychiatry** 1985 Aug; 147:119-26

Decision making in the treatment of depression by family medicine physicians. Zung WW, et al. **Compr Ther** 1985 Jul;11(7):19-23

Guidelines for the pharmacological management of depression. Creelman W, et al. **Conn Med** 1985 Sep;49(9):565-9

Severe depression treatment: experience using maprotiline (Ludiomil) in combination with clomipramine (Anafranil). Ovuga E. **East Afr Med J** 1985 Feb;62(2):79-81

Heterogeneity of major affective disorders. Biological and clinical evidence. Vita A, et al. **Encephale** 1985 Mar-Apr;11(2):71-7

Relationship between clinical effects, serum drug concentration and serotonin uptake inhibition in depressed patients treated with citalopram. A double-blind comparison of three dose levels. Bjerkenstedt L, et al. **Eur J Clin Pharmacol** 1985;28(5):553-7

Simultaneous measurement of various antidepressants in the plasma of depressed patients by high performance liquid chromatography. Yufu N, et al. **Folia Psychiatr Neurol Jpn** 1984;38(1):57-64

Long-term amitriptyline in chronic depression. Giller E Jr, et al. **Hillside J Clin Psychiatry** 1985;7(1):16-33

Neurochemical aspects of depression: the past and the future? Jesberger JA, et al. **Int J Neurosci** 1985 Jul;27(1-2):19-47 (240 ref.)

Tricyclic antidepressive treatment reinforced by reserpine. Moscovich D, et al. **Isr J Psychiatry Relat Sci** 1984;21(4):283-9

Spontaneous afternoon plasma cortisol in depression. Christensen P, et al. **J Affective Disord** 1985 May-Jun;8(3):271-8

Cerebrospinal fluid levels of amitriptyline, nortriptyline, imipramine and desmethylimipramine. Relationship to plasma levels and treatment outcome. Hanin I, et al. **J Affective Disord** 1985 Jul;9(1):69-78

The clinical interview for depression. Development, reliability and validity. Paykel ES. **J Affective Disord** 1985 Jul;9(1):85-96

A video analysis of the non-verbal behaviour of depressed patients before and after treatment. Ulrich G, et al. **J Affective Disord** 1985 Jul; 9(1):63-7

A proposed clinical approach to chronic and 'resistant' depressions: evaluation and treatment. Akiskal HS. **J Clin Psychiatry** 1985 Oct; 46(10 Pt 2):32-7

Patterns of attrition for psychosocial and pharmacologic treatments of depression. Last CG, et al. **J Clin Psychiatry** 1985 Sep;46(9):361-6

Tricyclic-resistant depression: treatment resistance or inadequate treatment? Lydiard RB. **J Clin Psychiatry** 1985 Oct;46(10):412-7 (93 ref.)

Nortriptyline pharmacokinetics and plasma levels: implications for clinical practice. Rubin EH, et al. **J Clin Psychiatry** 1985 Oct;46(10):418-24 (56 ref.)

Depression and serotonin metabolism: rationale for neurotransmitter precursor treatment. Byerley WF, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):191-206 (188 ref.)

Serial monitoring and achievement of steady state nortriptyline plasma levels in depressed children and adolescents: preliminary data. Geller B, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):213-6

Desipramine plasma levels and response in elderly melancholic patients. Nelson JC, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):217-20

Successful treatment of psychotic depression with carbamazepine. Schaffer CB, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):233-5

Effect of L-tryptophan on electroconvulsive therapy seizure time. Price WA, et al. **J Nerv Ment Dis** 1985 Oct;173(10):636-8

Early visual information processing in depressive patients treated with ORG 2766 (an ACTH 4-9 analogue). d'Elia G, et al. **Neuropsychobiology** 1985;13(1-2):63-8

Periodic sleep deprivation in drug-refractory depression. Dessauer M, et al. **Neuropsychobiology** 1985;13(3):111-6

Effect of bilateral olfactory bulbectomy in the rat, alone or in combination with antidepressants, on the learned immobility model of depression. Górka Z, et al. **Neuropsychobiology** 1985;13(1-2):26-30

Biochemical and diagnostic classification and serum drug levels: relation to antidepressive effect of imipramine. Møller SE, et al. **Neuropsychobiology** 1985;13(4):160-6

Antidepressant treatment of children: clinical relapse is unrelated to tricyclic plasma concentrations. Olig RM, et al. **Percept Mot Skills** 1985 Jun;60(3):879-89

Factors associated with response to lithium prophylaxis in DSM III major depression and bipolar disorder. Maj M, et al. **Pharmacopsychiatry** 1985 Sep;18(5):309-13

Oxaprotiline in the treatment of endogenous depressed inpatients an early clinical trial. Schmauss M, et al. **Pharmacopsychiatry** 1985 Jul; 18(4):282-5

Neurochemical and cognitive aspects of depression. Kidman A. **Prog Neurobiol** 1985;24(3):187-97

A controlled study of cellular immune function in affective disorders before and during somatic therapy. Albrecht J, et al. **Psychiatry Res** 1985 Jul;15(3):185-93

The GABA hypothesis of depression and antidepressant drug action. Bartholini G, et al. **Psychopharmacol Bull** 1985;21(3):385-8

Nocturnal serum melatonin in major depressive disorder before and after desmethylimipramine treatment. Brown RP, et al. **Psychopharmacol Bull** 1985;21(3):579-81

Melancholia in rodents: neurobiology and pharmacology. Henn FA, et al. **Psychopharmacol Bull** 1985;21(3):443-6

Imipramine for treatment of chronic depression. Kocsis JH, et al. **Psychopharmacol Bull** 1985;21(3):698-700

Effect of panic attacks on the treatment of atypical depressives. Liebowitz MR, et al. **Psychopharmacol Bull** 1985;21(3):558-61

Panic attacks in outpatients with depression: response to antidepressant treatment. Robinson DS, et al. **Psychopharmacol Bull** 1985; 21(3):562-7

Delayed biochemical changes following antidepressant treatment. Sugrue MF. **Psychopharmacol Bull** 1985;21(3):619-22

Addition of estrogen to imipramine in female-resistant depressives. Zohar J, et al. **Psychopharmacol Bull** 1985;21(3):705-6

Cardiovascular effects of amitriptyline in the treatment of elderly depressed patients. Christensen P, et al. **Psychopharmacology (Berlin)** 1985;87(2):212-5

Cianopramine and amitriptyline in the treatment of depressed patients--a placebo-controlled study. Hormazabal L, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):205-8

Informed consent in psychiatric research: preliminary findings from an ongoing investigation. Benson PR, et al. **Soc Sci Med** 1985; 20(12):1331-41

DESIPRAMINE

Monoamine uptake inhibitors attenuate ethanol intake in alcohol-preferring (P) rats. Murphy JM, et al. **Alcohol** 1985 Mar-Apr; 2(2):349-52

Plasma melatonin during desmethylimipramine treatment: evidence for changes in noradrenergic transmission. Cowen PJ, et al. **Br J Clin Pharmacol** 1985 Jun;19(6):799-805

Involvement of amygdaloid catecholaminergic mechanism in suppressive effects of desipramine and imipramine on duration of immobility in rats forced to swim. Araki H, et al. **Eur J Pharmacol** 1985 Jul 31; 113(3):313-8

Cerebrospinal fluid levels of amitriptyline, nortriptyline, imipramine and desmethylimipramine. Relationship to plasma levels and treatment outcome. Hanin I, et al. **J Affective Disord** 1985 Jul;9(1):69-78

Desipramine plasma levels and response in elderly melancholic patients. Nelson JC, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):217-20

The hypothalamic and neurohypophysial oxytocin content as influenced by desmethylimipramine in normal and pinealectomized white male rats. Guzek JW, et al. **J Neural Transm** 1985;62(1-2):125-36

Behavioral responses of high and low active male rats to the chronic ingestion of desipramine. Echandia EL, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):917-20

Nocturnal serum melatonin in major depressive disorder before and after desmethylimipramine treatment. Brown RP, et al. **Psychopharmacol Bull** 1985;21(3):579-81

Desmethylimipramine overdose: nonlinear kinetics in a slow hydroxylator. Spina E, et al. **Ther Drug Monit** 1985;7(2):239-41

DESOXYCORTICOSTERONE

Renal interstitial pressure in mineralocorticoid escape. Burnett JC Jr, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):F396-9

Deoxycorticosterone-stimulated bicarbonate secretion in rabbit cortical collecting ducts: effects of luminal chloride removal and in vivo acid loading. Garcia-Austt J, et al. **Am J Physiol** 1985 Aug; 249(2 Pt 2):F205-12

Adrenocortical hormones and brain growth: reversibility and differential sensitivity during development. Devenport LD, et al. **Exp Neurol** 1985 Oct;90(1):44-52

Control of sodium and potassium transport in the cortical collecting duct of the rat. Effects of bradykinin, vasopressin, and deoxycorticosterone. Tomita K, et al. **J Clin Invest** 1985 Jul;76(1):132-6

Hydrolysis of deoxycorticosterone-21-yl sulphate and dehydroepiandrosterone sulphate by microsomal preparations of human placentae: evidence for a common enzyme. Egyed J, et al. **J Endocrinol** 1985 Sep;106(3):295-301

Effects of corticosterone and 5 alpha-dihydrocorticosterone on brain excitability in the rat. Dubrovsky B, et al. **J Neurosci Res** 1985; 14(1):117-28

The dependence of the salt appetite of the rat on the hormonal consequences of sodium deficiency. Epstein AN. **J Physiol (Paris)** 1984; 79(6):496-8

DEXTROAMPHETAMINE

A comparison of the acute effects of dextroamphetamine and fenfluramine in depression. Ward NG, et al. **Biol Psychiatry** 1985 Oct; 20(10):1090-7

Biochemical and behavioral changes in rats during and after chronic d-amphetamine exposure. Vogel WH, et al. **Drug Alcohol Depend** 1985 Jun;15(3):245-53

Antagonism of the amphetamine cue by both classical and atypical antipsychotic drugs. Nielsen EB, et al. **Eur J Pharmacol** 1985 May 8; 111(2):167-76

Demonstration of reduced levels of zinc in rat brain after treatment with d-amphetamine, but not after treatment with reserpine. Szerdahelyi P, et al. **Histochemistry** 1985;83(2):181-7

Psychostimulant plasma concentration and learning performance. Kupietz SS, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):293-5

Repeated treatment with imipramine or amitriptyline increases the locomotor response of rats to (+)-amphetamine given into the nucleus accumbens. Maj J, et al. **J Pharm Pharmacol** 1985 May;37(5):362-4

Cardiovascular effects of two potential beta-hydroxylase inhibitors. Venugopalan CS, et al. **J Pharm Sci** 1985 Jun;74(6):681-4

Tolerance pattern to amphetamine anorexia after selective lesions in the hypothalamic dopaminergic projection. Bhakthavatsalam P, et al. **Life Sci** 1985 Aug 19;37(7):635-43

Effects of triethyltin and its interaction with d-amphetamine and chlorpromazine on responding under a multiple schedule of food presentation in rats. Rastogi SK, et al. **Neurobehav Toxicol Teratol** 1985 May-Jun;7(3):239-42

Altered central monoamine response to D-amphetamine in rats chronically exposed to inorganic lead. Lasley SM, et al. **Neurochem Res** 1985 Jul;10(7):933-44

The effects of MIF-I, beta-endorphin and alpha-MSH on d-amphetamine induced paradoxical behavioral thermoregulation: possible involvement of the dopaminergic system. Yehuda S, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):189-92

Acute and chronic behavioral interactions between phencyclidine (PCP) and amphetamine: evidence for a dopaminergic role in some PCP-induced behaviors. Greenberg BD, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):99-105

Behaviorally equivalent stressors differentially modify the monoamine altering property of d-amphetamine. Klauenberg BJ, et al. **Pharmacol Biochem Behav** 1985 Sep;23(3):417-23

The discriminative stimulus and subjective effects of d-amphetamine in humans. Chait LD, et al. **Psychopharmacology (Berlin)** 1985; 86(3):307-12

A conveyor belt task for assessing visuo-motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d-amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):125-31

Amphetamine-induced enhancement of ethanol consumption: role of central catecholamines. Levy AD, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):233-6

Comparison between locomotor activity changes produced by phencyclidine and D-amphetamine in CD-1 male mice. Stavchansky S, et al. **Res Commun Chem Pathol Pharmacol** 1985 May; 48(2):189-202

DIAZEPAM

Psychomotor effects of alprazolam and diazepam during acute and subacute treatment, and during the follow-up phase. Aranko K, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):364-72

Indications and contraindications for chronic anxiolytic treatment: is there tolerance to the anxiolytic effect? Rickels K, et al. **Adv Biochem Psychopharmacol** 1985;40:193-204

Comparative bioavailability studies on brands of diazepam tablets. Ogunbona FA, et al. **Afr J Med Med Sci** 1985 Mar-Jun; 14(1-2):21-5

Effects of single and repeated application of clonazepam and diazepam combined with cyproheptadine on apomorphine stereotypy in rats. Georgiev VP, et al. **Agressologie** 1985 Jan;26(1):57-60

No cross-tolerance between the stimulatory and depressant actions of benzodiazepines in mice. File SE, et al. **Behav Brain Res** 1985 Sep; 17(1):1-7

The genetic architecture of hyponeophagia and the action of diazepam in rats. Shephard RA, et al. **Behav Genet** 1985 May;15(3):265-86

The effect of nonsedating doses of diazepam on regional cerebral blood flow. Mathew RJ, et al. **Biol Psychiatry** 1985 Oct;20(10):1109-16

Responsiveness to oral diazepam in the elderly: relationship to total and free plasma concentrations. Swift CG, et al. **Br J Clin Pharmacol** 1985 Aug;20(2):111-8

Correlation of [3H]diazepam binding density with anxiolytic locus in the amygdaloid complex of the rat. Thomas SR, et al. **Brain Res** 1985 Sep 2;342(1):85-90

Liquid-chromatographic assay of diazepam and its major metabolites in serum, and application to pharmacokinetic study of high doses of diazepam in schizophrenics. Tada K, et al. **Clin Chem** 1985 Oct; 31(10):1712-5

A comparison of diazepam and midazolam as sedatives for minor oral surgery. Skelly AM, et al. **Eur J Anaesthesiol** 1984 Sep;1(3):253-67

Interactions between smectite, a mucus stabilizer, and acidic and basic drugs. In vitro and in vivo studies. Albengres E, et al. **Eur J Clin Pharmacol** 1985;28(5):601-5

Diazepam: kinetic profiles in various brain areas, plasma and erythrocytes after chronic administration in the rat. Hariton C, et al. **Eur J Drug Metab Pharmacokinet** 1985 Apr-Jun;10(2):105-11

Inhibition of diazepam metabolism in microsomal- and perfused liver preparations of the rat by desmethyldiazepam, N-methyloxazepam and oxazepam. Savenije-Chapel EM, et al. **Eur J Drug Metab Pharmacokinet** 1985 Jan-Mar;10(1):15-20

Liquid chromatographic determination of diazepam in tablets: collaborative study. Tsougros M. **J Assoc Off Anal Chem** 1985 May-Jun; 68(3):545-6

The pH dependence of the thermodynamics of the interaction of diazepam with human serum albumin. Janssen LH, et al. **J Biol Chem** 1985 Sep 25;260(21):11442-5

Comparison of models describing the sorption of nitroglycerin and diazepam by plastic infusion systems: diffusion and compartment models. Kowaluk EA, et al. **J Pharm Sci** 1985 Jun;74(6):625-33

Thymidine transport and metabolism in choroid plexus: effect of diazepam and thiopental. Spector R. **J Pharmacol Exp Ther** 1985 Oct; 235(1):16-9

Valproate increases diazepam impregnation selectively in CNS of the rat after subchronic administration. Hariton C, et al. **Life Sci** 1985 Oct 7;37(14):1343-9

Pharmacokinetics of diazepam after intravenous, intramuscular and oral administration to humans. Wichliński LM, et al. **Mater Med Pol** 1985 Jan-Mar;17(1):44-6

The interdiction of diazepam provision. Mason JC. **Milit Med** 1985 Jul; 150(7):376-7

Benzodiazepine-receptor mediated inhibition of isolation-induced aggression in mice. Skolnick P, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):17-20

The reinforcing properties of diazepam under several conditions in the rhesus monkey. Bergman J, et al. **Psychopharmacology (Berlin)** 1985; 86(1-2):108-13

Drug preference in normal volunteers: effects of age and time of day. de Wit H, et al. **Psychopharmacology (Berlin)** 1985;87(2):186-93

A conveyor belt task for assessing visuo-motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d-amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):125-31

Comparative pharmacokinetics and pharmacodynamics of lorazepam, alprazolam and diazepam. Ellinwood EH Jr, et al. **Psychopharmacology (Berlin)** 1985;86(4):392-9

Diazepam administration to mice prevents some of the changes in monoamine-mediated behaviour produced by repeated electroconvulsive shock treatment. Green AR, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):190-3

Effects of diazepam and triazolam on auditory and visual thresholds and reaction times in the baboon. Lukas SE, et al. **Psychopharmacology (Berlin)** 1985;87(2):167-72

Evaluation of signal detection theory on the effects of psychotropic drugs on critical flicker-fusion frequency in normal subjects. MacNab MW, et al. **Psychopharmacology (Berlin)** 1985;85(4):431-5

Mechanisms of the initial treatment phenomenon to diazepam in the rat. Mokler DJ, et al. **Psychopharmacology (Berlin)** 1985;87(2):242-6

A beta-carboline antagonizes benzodiazepine actions but does not precipitate the abstinence syndrome in cats. Ongini E, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):132-6

Effects of alprazolam and diazepam on the daytime sleepiness of non-anxious subjects. Seidel WF, et al. **Psychopharmacology (Berlin)** 1985;87(2):194-7

[Effect of diazepam on interference processes] Vinitskil IM, et al. **Farmakol Toksikol** 1985 Jul-Aug;48(4):38-41 (Eng. Abstr.) **(Rus)**

[Importance of protein binding of lorazepam in its clinical management] Aguilera Celorrio L, et al. **Rev Esp Anestesiol Reanim** 1985 May-Jun; 32(3):115-8 (Eng. Abstr.) **(Spa)**

DIBENZAZEPINES

Citalopram versus mianserin. A controlled, double-blind trial in depressed patients. de Wilde J, et al. **Acta Psychiatr Scand** 1985 Jul; 72(1):89-96

New implications of antidepressant therapy in neuropsychopharmacology: focus on mianserin. 14th Congress of the Collegium Internationale Neuro-Psychopharmacologicum. Florence, Italy, 19-23 June 1984. **Acta Psychiatr Scand [Suppl]** 1985;320:1-105

Treatment of childhood and adolescent depression with mianserin. Dugas M, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:48-53

A double-blind group comparison of mianserin and clomipramine in the treatment of mildly depressed psychiatric out-patients. Dunbar GC, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:60-6

Depression and anxiety: mianserin and nomifensine compared in a double-blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67-74

Mianserin is better tolerated and more effective in depression than a nomifensine-clobazam combination: a double-blind study. Levin A, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:75-80

Changes in sleep EEG architecture during the treatment of depressed patients with mianserin. Mendlewicz J, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:26-9

Profiles of antidepressant activity with the Montgomery-Asberg Depression Rating Scale. Montgomery SA, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:38-42

Adrenoreceptor interactions of the enantiomers and metabolites of mianserin: are they responsible for the antidepressant effect? Pinder RM. **Acta Psychiatr Scand [Suppl]** 1985;320:1-9 (29 ref.)

Oxidation in H2O and D2O of 6-ethyl-5H-dibenz(c,e)azepine and 1-methylnicotinamide by aldehyde oxidase from rabbit liver. Thomas HG, et al. **Arch Biochem Biophys** 1985 Sep;241(2):649-55

Trimipramine, a tricyclic antidepressant exerting atypical actions on the central noradrenergic system. Hauser K, et al. **Eur J Pharmacol** 1985 Apr 23;111(1):23-30

Cardiovascular effects of single doses of the antidepressants amitriptyline and lofepramine in healthy subjects. Stern H, et al. **Pharmacopsychiatry** 1985 Jul;18(4):272-7

Early relapse after sudden withdrawal or dose reduction of clozapine [letter] Perényi A, et al. **Psychopharmacology (Berlin)** 1985; 86(1-2):244

Carpipramine metabolism in the rat, rabbit and dog and in man after oral administration. Bieder A, et al. **Xenobiotica** 1985 May;15(5):421-35

[Clozapine and agranulocytosis] Xu SH. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Oct; 17(5):271-2 (Eng. Abstr.) **(Chi)**

[An analysis of 106 cases of schizophrenia treated with clozapine] Yang JS. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Aug; 17(4):242-4 (Eng. Abstr.) **(Chi)**

[Schizophrenically disordered time perception and its modification by neuroleptics] Heim M, et al. **Psychiatr Neurol Med Psychol (Leipz)** 1985 Jul;37(7):410-5 (Eng. Abstr.) **(Ger)**

[Treatment of anxious-depressive syndromes with Mianserin hydrochloride. Statistical evaluation of the data by Student's 't test'] Spinetti G, et al. **Minerva Psichiatr** 1985 Jan-Mar;26(1):79-86 (Eng. Abstr.) **(Ita)**

[Effect of leponex on the ultrastructure of the brain] Uranova NA. **Zh Nevropatol Psikhiatr** 1985;85(7):1006-11 (Eng. Abstr.) **(Rus)**

DIBENZOTHIEPINS

High-performance liquid chromatographic determination of 3-hydroxymethyl-dibenzo[b,f]thiepin 5,5-dioxide and its acid metabolite in human plasma and urine. Slobodzian DK, et al. **J Chromatogr** 1985 Feb 27;338(1):253-8

Reduced head-twitch response to quipazine of rats previously treated with methiothepin: possible involvement of dopaminergic system. Dall'Olio R, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):43-8

[Clinical effectiveness of isofloxythepin--an open study] Zapletálek M, et al. **Cesk Psychiatr** 1985 Aug;81(4):242-6 (Eng. Abstr.) **(Cze)**

DIBENZOXAZEPINES

Determination of amoxapine and metabolites in plasma by liquid chromatography with electrochemical detection. Suckow RF, et al. **J Chromatogr** 1985 Feb 27;338(1):225-9

Acute renal failure secondary to non-traumatic rhabdomyolysis following amoxapine overdose. Frendin TJ, et al. **NZ Med J** 1985 Aug 28; 98(785):690-1

DISCRIMINATION (PSYCHOLOGY)

Chlordiazepoxide and successive discrimination: different effects on acquisition and performance. McNaughton N. **Pharmacol Biochem Behav** 1985 Sep;23(3):487-94

Discriminative stimulus properties and schedule effects of fencamfamine in rats. Risner ME, et al. **Pharmacol Biochem Behav** 1985 Sep; 23(3):449-56

Trends in drug discrimination research analysed with a cross-indexed bibliography, 1982-1983. Stolerman IP, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):1-11 (191 ref.)

DISCRIMINATION LEARNING

Psychopharmacological profile of cholecystokinin using the self-stimulation and the drug discrimination paradigms. De Witte P, et al. **Ann NY Acad Sci** 1985;448:470-87

The effects of chlorpromazine and imipramine on rate and stimulus control of matching to sample. Newland MC, et al. **J Exp Anal Behav** 1985 Jul;44(1):49-68

The non-sedating anxiolytic CGS 9896 produces discriminative stimuli that may be related to an anxioselective effect. Bennett DA. **Life Sci** 1985 Aug 26;37(8):703-9

Chlordiazepoxide and successive discrimination: different effects on acquisition and performance. McNaughton N. **Pharmacol Biochem Behav** 1985 Sep;23(3):487-94

The 5-HT syndrome and the drug discrimination paradigm in rats: application in behavioral studies on the central 5-HT system. Ortmann R. **Pharmacopsychiatry** 1985 Mar;18(2):198-201

The discriminative stimulus and subjective effects of d-amphetamine in humans. Chait LD, et al. **Psychopharmacology (Berlin)** 1985;

86(3):307-12

Drug discrimination training with a single choice trial per session. Tomie A, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):217-22

DOPA

Melanocyte metabolites in the urine of people of different skin colour. Wirestrand LE, et al. **Acta Derm Venereol (Stockh)** 1985;65(4):345-8

The effect of ring-fluorination on the rate of O-methylation of dihydroxyphenylalanine (DOPA) by catechol-O-methyltransferase: significance in the development of 18F-PETT scanning agents. Creveling CR, et al. **Biochem Biophys Res Commun** 1985 Aug 15; 130(3):1123-31

Regulation of galactokinase gene expression in Tetrahymena thermophila. II. Identification of 3,4-dihydroxyphenylalanine as a primary effector of adrenergic control of galactokinase expression. Ness JC, et al. **J Biol Chem** 1985 Aug 25;260(18):10013-8

Inhibition of tyrosine hydroxylation in rat striatal tissue slices by 1-methyl-4-phenylpyridinium ion. Hirata Y, et al. **Neurosci Lett** 1985 Jun 24;57(3):301-5

[Synthesis of tyrosine and 3,4-dihydroxyphenylalanine by Citrobacter freundii bacteria from lactic acid] Kupletskaia MB. **Prikl Biokhim Mikrobiol** 1985 May-Jun;21(3):342-8 (Eng. Abstr.) **(Rus)**

DOPAMINE

Influence of beta-receptor stimulation on catecholamine and phospholipid concentrations in lungs of fetal rabbits. Urban J, et al. **Acta Paediatr Hung** 1985;26(2):127-32

Effects of lesions and ganglioside GM1 treatment on striatal polyamine levels and nigral DA neurons. A role of putrescine in the neurotropic activity of gangliosides. Agnati LF, et al. **Acta Physiol Scand** 1985 Aug; 124(4):499-506

Calcium, cAMP, and dopamine affect single mammotrophs assayed by hemolytic plaques. Anderson JM, et al. **Am J Physiol** 1985 Oct; 249(4 Pt 1):E337-44

Blockade of renal effects of dopamine in the dog by the DA1 antagonist SCH 23390. Frederickson ED, et al. **Am J Physiol** 1985 Aug; 249(2 Pt 2):F236-40

Blinking frequency and dopamine availability [letter] Ostow M. **Am J Psychiatry** 1985 Aug;142(8):994

In vitro measurement of dopamine concentration with carbon fiber electrode. Akiyama A, et al. **Anal Chem** 1985 Jul;57(8):1518-22

Fast in vivo monitoring of dopamine release in the rat brain with differential pulse amperometry. Marcenac F, et al. **Anal Chem** 1985 Jul; 57(8):1778-9

Flow injection amperometric determination of ascorbic acid and dopamine at a sessile mercury drop electrode without deoxygenation. Fogg AG, et al. **Analyst** 1985 Apr;110(4):341-3

The influence of verapamil on dopamine's ability to augment cardiac output. Sturm JT. **Ann Emerg Med** 1985 Oct;14(10):945-7

Cholecystokinin potentiation of dopamine-mediated behaviors in the nucleus accumbens. Crawley JN. **Ann NY Acad Sci** 1985;448:283-92

Interactions of cholecystokinin and dopamine in the nucleus accumbens. Wang RY, et al. **Ann NY Acad Sci** 1985;448:352-60

The effect of dopamine, apomorphine and piribedil on the mesenterial blood flow of the cat. György L, et al. **Arch Int Pharmacodyn Ther** 1985 May;275(1):22-32

Change of catecholamine turnover in ovary during the rat estrous cycle. Nagahara Y, et al. **Asia Oceania J Obstet Gynaecol** 1985 Jun; 11(2):261-4

Differential effects of intrafrontocortical microinjections of dopamine agonists and antagonists on circling behavior of rats. Stewart RJ, et al. **Behav Brain Res** 1985 Sep;17(1):67-72

Dopamine-mediated increases in nigral substance P-like immunoreactivity. Ritter JK, et al. **Biochem Pharmacol** 1985 Sep 1; 34(17):3161-6

Metabolism of carbidopa to alpha-methyldopamine and alpha-methylnorepinephrine in rats. Shelton RC, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3623-6

Purification and kinetic characterization of a dopamine-sulfating form of phenol sulfotransferase from human brain. Whittemore RM, et al. **Biochemistry** 1985 May 7;24(10):2477-82

Dopamine stimulated fucosylation of rat hippocampal proteins in vitro. A histoautoradiographic study. Pohle W, et al. **Biomed Biochim Acta** 1985;44(4):527-35

The effects of dopexamine on the cardiovascular system of the dog. Brown RA, et al. **Br J Pharmacol** 1985 Jul;85(3):609-19

In vitro dopamine biosynthesis in the median eminence of rat hypothalamic slices: possible involvement of a Na+-Ca2+ exchange mechanism. Arita J, et al. **Brain Res** 1985 Jul 15;338(2):384-6

Postnatal ontogenesis of the dopaminergic innervation in the rat anterior cingulate cortex (area 24). Immunocytochemical and catecholamine fluorescence histochemical analysis. Berger B, et al. **Brain Res** 1985 Jul;353(1):31-47

Regional depletion of central nervous system catecholamines: effects on blood pressure and drinking behavior. Gordon FJ, et al. **Brain Res** 1985 Oct 21;345(2):285-97

Primary cultures from defined brain areas; effects of seeding time on the development of beta-adrenergic- and dopamine-stimulated cAMP-activity during cultivation. Hansson E. **Brain Res** 1985 Aug; 353(2):187-92

Dopamine D-2 receptors in rat caudate-putamen: the lateral to medial gradient does not correspond to dopaminergic innervation. Joyce JN, et al. **Brain Res** 1985 Jul 15;338(2):209-18

Coexistence of immunoreactivities for glutamate decarboxylase and tyrosine hydroxylase in some neurons in the periglomerular region of the rat main olfactory bulb: possible coexistence of gamma-aminobutyric acid (GABA) and dopamine. Kosaka T, et al. **Brain Res** 1985 Sep 16; 343(1):166-71

In vivo voltammetric and behavioural evidence for somatodendritic autoreceptor control of mesolimbic dopamine neurones. Maidment NT, et al. **Brain Res** 1985 Jul 15;338(2):317-25

Suppression of MPTP-induced dopaminergic neurotoxicity in mice by nomifensine and L-DOPA. Melamed E, et al. **Brain Res** 1985 Sep 9; 342(2):401-4

Tyrosine hydroxylase immunohistochemistry fails to demonstrate dopaminergic interplexiform cells in the turtle retina. Nguyen-Legros J, et al. **Brain Res** 1985 Jul 29;339(2):323-8

Effects on the caudate spindle in rats of taurine and gamma-aminobutyric acid (GABA) microinjected into the substantia nigra: involvement of the dopaminergic system. Okuyama S, et al. **Brain Res** 1985 Sep 9; 342(2):366-8

SCH 23390, a selective D1 dopamine receptor blocker, enhances the firing rate of nigral dopaminergic neurons but fails to activate striatal tyrosine hydroxylase. Onali P, et al. **Brain Res** 1985 Aug 5;340(1):1-7

Neurotensin depolarizes substantia nigra dopamine neurones. Pinnock RD. **Brain Res** 1985 Jul 8;338(1):151-4

Dopamine changes the shape of action potentials in hippocampal pyramidal cells. Pockett S. **Brain Res** 1985 Sep 9;342(2):386-90

Sodium-independent binding of [3H]cocaine in mouse striatum is serotonin related. Reith ME, et al. **Brain Res** 1985 Sep 2;342(1):145-8

Simultaneous voltammetric and chemical monitoring of dopamine release in situ. Rice ME, et al. **Brain Res** 1985 Aug 5;340(1):151-5

Monoamine release from dopamine-depleted rat caudate nucleus reinnervated by substantia nigra transplants: an in vivo electrochemical study. Rose G, et al. **Brain Res** 1985 Aug 19;341(1):92-100

In vivo analysis of dopamine and its metabolites in the caudate nucleus during euthermia and hibernation. Salzman SK, et al. **Brain Res** 1985 Sep 16;343(1):95-103

Calmodulin-dependent adenylate cyclase in rat retina and the response to dopamine. Sano M. **Brain Res** 1985 Oct 21;345(2):337-40

The effect of water-deprivation on locomotor activity in rats treated with 6-hydroxydopamine. Seiden LS, et al. **Brain Res** 1985 Jul 1; 337(2):225-32

Organization of diencephalic dopamine neurones projecting to the spinal cord in the rat. Skagerberg G, et al. **Brain Res** 1985 Sep 9; 342(2):340-51

Behavioral study after local injection of 6-hydroxydopamine into the nucleus accumbens in the rat. Taghzouti K, et al. **Brain Res** 1985 Sep 30;344(1):9-20

Interaction of vasopressin with the nigro-striatal dopamine system: site and mechanism of action. van Heuven-Nolsen D, et al. **Brain Res** 1985 Jul 1;337(2):269-76

Effects of mazindol on rat lateral hypothalamic neurons. Sikdar SK, et al. **Brain Res Bull** 1985 Jul;15(1):33-8

Identification of dopamine-containing cell bodies in the dorsal and median raphe nuclei of the rat brain using tyrosine hydroxylase immunochemistry. Trulson ME, et al. **Brain Res Bull** 1985 Aug; 15(2):229-34

Simultaneous recording of substantia nigra neurons and voltammetric release of dopamine in the caudate of behaving cats. Trulson ME. **Brain Res Bull** 1985 Aug;15(2):221-3

Vagal afferent activity and renal nerve release of dopamine. Morgunov N, et al. **Can J Physiol Pharmacol** 1985 Jun;63(6):636-41

Schizophrenia: an amotivational syndrome in men. Lewine R. **Can J Psychiatry** 1985 Aug;30(5):316-8 (17 ref.)

The interaction of trh and dopaminergic mechanisms in the regulation of stimulated prolactin release in man. Ho KY, et al. **Clin Endocrinol (Oxf)** 1985 Jul;23(1):7-16

Amine-containing neurons in the brain of Lymnaea stagnalis: distribution and effects of precursors. Audesirk G. **Comp Biochem Physiol** [A] 1985; 81(2):359-65

Effect of gonadectomy on brain catecholamines during the postnatal period. Leret ML, et al. **Comp Biochem Physiol** [C] 1985; 81(2):405-9

Effect of microelectrophoretically applied acetylcholine, noradrenaline, dopamine and serotonin on the discharge of paraventricular oxytocinergic neurones in the rat. Honda K, et al. **Endocrinol Jpn** 1985 Feb;32(1):127-33

Stimulation of somatostatin release in vitro by synthetic human growth hormone-releasing factor by a nondopaminergic mechanism. Aguila

MC, et al. **Endocrinology** 1985 Aug;117(2):762–5

Stimulation of the adenosine 3',5'–monophosphate and the Ca2+ messenger systems together reverse dopaminergic inhibition of prolactin release. Delbeke D, et al. **Endocrinology** 1985 Aug;117(2):439–46

Examination of the effects of epinephrine, norepinephrine, and dopamine on aldosterone production in bovine glomerulosa cells in vitro. Sequeira SJ, et al. **Endocrinology** 1985 Nov;117(5):1947–52

Effect of dopamine agonists and antagonists on the binding of [3H]estradiol to its receptors in the anterior pituitary gland of male rats. Szijan I, et al. **Endocrinology** 1985 Nov;117(5):1742–8

Effects of GABA receptor agonists on [3H]dopamine release from median eminence and pituitary neurointermediate lobe. Anderson R, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):109–12

The dynamics of dopamine metabolism in the rat superior cervical, coeliac and mesenteric ganglia. Dalmaz Y, et al. **Eur J Pharmacol** 1985 Aug 15;114(2):209–17

Mesolimbic dopaminergic neurons are not spared by MPTP neurotoxicity in mice. Melamed E, et al. **Eur J Pharmacol** 1985 Aug 7; 114(1):97–100

Inhibition of protein carboxylmethylation and dopamine autoreceptor functioning. Saller CF, et al. **Eur J Pharmacol** 1985 Apr 23; 111(1):17–22

Lack of evidence supporting a role for dopamine in 1–methyl–4–phenyl–1,2,3,6–tetrahydropyridine neurotoxicity. Schmidt CJ, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):149–50

Effect of N–methyl–4–phenyl–1,2,3,6–tetrahydropyridine (MPTP) on age–related changes in dopamine turnover and transporter function in the mouse striatum. Sershen H, et al. **Eur J Pharmacol** 1985 Jul 11; 113(1):135–6

Morphine increases the activity of midbrain dopamine neurons in vitro. Trulson ME, et al. **Eur J Pharmacol** 1985 Aug 7;114(1):105–9

Spatial distribution of visual pigment and dopamine in the bullfrog retina. Makino–Tasaka M, et al. **Exp Eye Res** 1985 Jun;40(6):767–78

Striatal dopamine after cortical injury. Boyeson MG, et al. **Exp Neurol** 1985 Aug;89(2):479–83

Serotonergic conversion of MPTP and dopaminergic accumulation of MPP+. Shen RS, et al. **FEBS Lett** 1985 Sep 23;189(2):225–30

Dopamine in manic depressive illness. A pharmacological synthesis. Silverstone T. **J Affective Disord** 1985 May–Jun;8(3):225–31

Regulation of pro–opiomelanocortin synthesis by dopamine and cAMP in the amphibian pituitary intermediate lobe. Loh YP, et al. **J Biol Chem** 1985 Jul 25;260(15):8956–63

Patterns of muscarinic cholinergic binding in the striatum and their relation to dopamine islands and striosomes. Nastuk MA, et al. **J Comp Neurol** 1985 Jul 8;237(2):176–94

Time–dependent effects of oestradiol and progesterone on hypothalamic catecholamine turnover in ovariectomized rats. Hiemke C, et al. **J Endocrinol** 1985 Sep;106(3):303–9

Effects of dopamine and morphine on immunoreactive somatostatin and LH–releasing hormone secretion from hypothalamic fragments in vitro. Lengyel AM, et al. **J Endocrinol** 1985 Sep;106(3):317–22

Guinea pig striatum as a model of human dopamine deamination: the role of monoamine oxidase isozyme ratio, localization, and affinity for substrate in synaptic dopamine metabolism. Azzaro AJ, et al. **J Neurochem** 1985 Sep;45(3):949–56

1–Methyl–4–phenyl–1,2,3,6–tetrahydropyridine: correspondence of its binding sites to monoamine oxidase in rat brain, and inhibition of dopamine oxidative deamination in vivo and in vitro. Bocchetta A, et al. **J Neurochem** 1985 Sep;45(3):673–6

Relationship between catechol–O–methyltransferase and phenolsulfotransferase in the metabolism of dopamine in the rat brain. Buu NT. **J Neurochem** 1985 Nov;45(5):1612–9

Study of dopamine turnover by monitoring the decline of dopamine metabolites in rat CSF after alpha–methyl–p–tyrosine. Mignot E, et al. **J Neurochem** 1985 Nov;45(5):1527–33

Binding of [3H]SCH23390 in rat brain: regional distribution and effects of assay conditions and GTP suggest interactions at a D1–like dopamine receptor. Schulz DW, et al. **J Neurochem** 1985 Nov;45(5):1601–11

[3H]Threo–(+/–)–methylphenidate binding to 3,4–dihydroxyphenylethylamine uptake sites in corpus striatum: correlation with the stimulant properties of ritalinic acid esters. Schweri MM, et al. **J Neurochem** 1985 Oct;45(4):1062–70

Serotonin agonists reduce dopamine synthesis in the striatum only when the impulse flow of nigro–striatal neurons is intact. Spampinato U, et al. **J Neurochem** 1985 Sep;45(3):980–2

Cholecystokinin potentiates dopamine–mediated behaviors: evidence for modulation specific to a site of coexistence. Crawley JN, et al. **J Neurosci** 1985 Aug;5(8):1972–83

Two different mechanisms of calcium spike modulation by dopamine. Paupardin–Tritsch D, et al. **J Neurosci** 1985 Sep;5(9):2522–32

The release of endogenous dopamine from rat striatum during incubation in vitro. Snape BM, et al. **J Neurosci Methods** 1985 Jun;14(1):53–64

Dopaminergic modulation of neuromuscular transmission in the prawn. Miller MW, et al. **J Physiol (Lond)** 1985 Jun;363:363–75

Modification of antinociceptive action of morphine by dopamine agonist and antagonist in mice. Kamata K, et al. **Jpn J Pharmacol** 1985 May; 38(1):113–5

Dopaminergic modulation of the renal effect of arginine–vasopressin in water–loaded rats. Koyama S, et al. **Jpn J Pharmacol** 1985 May; 38(1):25–30

Tolerance pattern to amphetamine anorexia after selective lesions in the hypothalamic dopaminergic projection. Bhakthavatsalam P, et al. **Life Sci** 1985 Aug 19;37(7):635–43

Influence of selective, reversible inhibitors of monoamine oxidase on the prolonged depletion of striatal dopamine by 1–methyl–4–phenyl–1,2,3,6–tetrahydropyridine in mice. Fuller RW, et al. **Life Sci** 1985 Sep 23;37(12):1089–96

Free and conjugated catecholamines in digestive tissues of rats. Gaudin C, et al. **Life Sci** 1985 Oct 21;37(16):1469–74

Lack of functional evidence for the involvement of sigma opiate receptors in the actions of the 3–PPP enantiomers on central dopaminergic systems: discrepancies between in vitro and in vivo observations. Hjorth S, et al. **Life Sci** 1985 Aug 19;37(7):673–84

Dopamine–beta–hydroxylase inhibition acutely stimulates rats hypothalamic noradrenaline and dopamine neuronal activity as assessed from metabolic ratios and circulating glucose and ACTH responses. Smythe GA, et al. **Life Sci** 1985 Sep 2;37(9):841–7

Very rapid turnover of dopamine in noradrenaline cell body regions. Andén NE, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 May; 329(3):258–63

An electrophysiological analysis of the actions of the 3–PPP enantiomers on the nigrostriatal dopamine system. Clark D, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):344–54

Cyclic AMP facilitates the electrically evoked release of radiolabelled noradrenaline, dopamine and 5–hydroxytryptamine from rat brain slices. Schoffelmeer AN, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jul;330(1):74–6

Altered central monoamine response to D–amphetamine in rats chronically exposed to inorganic lead. Lasley SM, et al. **Neurochem Res** 1985 Jul;10(7):933–44

In vitro dopamine release from the rat striatum: diurnal rhythm and its modification by the estrous cycle. Dluzen D, et al. **Neuroendocrinology** 1985 Aug;41(2):97–100

Hypothalamic monoaminergic activity and pituitary function in male rats with estrogen–induced pituitary hyperplasia. Terry LC, et al. **Neuroendocrinology** 1985 Oct;41(4):269–75

The role of central dopaminergic systems in the behavioral effects of H–Phe–Ile–Tyr–His–Ser–Tyr–Lys–OH. Vécsei L, et al. **Neuropeptides** 1985 Jun;6(3):183–90

S(+)Apomorphines. Selective inhibition of excitatory effects of dopamine injected into the limbic system of the rat. Campbell A, et al. **Neuropharmacology** 1985 May;24(5):391–9

Intracerebroventricular administration of 1–methyl–4–phenyl–1,2,3,6–tetrahydropyridine (MPTP) and its metabolite 1–methyl–4–phenylpyridinium ion (MPP+) decrease dopamine and increase acetylcholine in the mouse neostriatum. Cavalla D, et al. **Neuropharmacology** 1985 Jun;24(6):585–6

Oxytocin and a C–terminal derivative (Z–prolyl–D–leucine) attenuate tolerance to and dependence on morphine and interact with dopaminergic neurotransmission in the mouse brain. Kovács GL, et al. **Neuropharmacology** 1985 May;24(5):413–9

Intracerebroventricular administration of cholecystokinin inhibits the activity of the dopaminergic and serotoninergic systems of the brain. Vasar EE, et al. **Neurosci Behav Physiol** 1985 May–Jun;15(3):232–6

Dopamine–sensitive adenylate cyclase in rabbit portal vein. Amenta F. **Neurosci Lett** 1985 May 23;56(3):279–82

Electrophysiological properties of single units in dopamine–rich mesencephalic transplants in rat brain. Arbuthnott G, et al. **Neurosci Lett** 1985 Jun 12;57(2):205–10

Dopaminergic agents differentially alter beta–endorphin processing patterns in the rat pituitary neurointermediate lobe. Autelitano DJ, et al. **Neurosci Lett** 1985 Aug 16;59(1):141–6

Dopaminergic toxicity after the stereotaxic administration of the 1–methyl–4–phenylpyridinium ion (MPP+) to rats. Heikkila RE, et al. **Neurosci Lett** 1985 Aug 16;59(1):135–40

Effects of 1–methyl–4–phenyl–1,2,3,6–tetrahydropyridine (MPTP) and several of its analogues on the dopaminergic nigrostriatal pathway in mice. Heikkila RE, et al. **Neurosci Lett** 1985 Jul 4;58(1):133–7

Muscarine–binding sites localized to cortical dopamine terminals. Liskowsky DR, et al. **Neurosci Lett** 1985 Jul 31;58(2):229–33

In vivo voltammetric determination of the kinetics of dopamine metabolism in the rat. Michael AC, et al. **Neurosci Lett** 1985 May 23; 56(3):365–9

1–Methyl–4–phenylpyridine (MPP+) is toxic to mesencephalic dopamine neurons in culture. Mytilineou C, et al. **Neurosci Lett** 1985 Jun 4; 57(1):19–24

Effects on the caudate spindle in rats of dopamine microinjected into the caudate nucleus. Okuyama S, et al. **Neurosci Lett** 1985 Aug 16; 59(1):27–32

Effects of N–methyl–4–phenyl–1,2,3,6–tetrahydropyridine and its metabolite, N–methyl–4–phenylpyridinium ion, on dopaminergic nigrostriatal neurons in the mouse. Perry TL, et al. **Neurosci Lett** 1985

Aug 5;58(3):321-6

Sodium-dependent, calmodulin-dependent transmitter release from synaptosomes. Sandoval ME, et al. **Neurosci Lett** 1985 May 23; 56(3):271-7

In vitro demonstration of dopamine uptake by neostriatal serotonergic neurons of the rat. Schmidt CJ, et al. **Neurosci Lett** 1985 Aug 16; 59(1):9-14

Suckling decreases dopamine turnover in both medial and lateral aspects of the median eminence in the rat. Selmanoff M, et al. **Neurosci Lett** 1985 Jun 4;57(1):25-30

Opposite effects of monosodium glutamate on the dopaminergic and GABAergic innervations of the median eminence and the intermediate lobe in the mouse. Stoeckel ME, et al. **Neurosci Lett** 1985 May 23; 56(3):249-55

Laminar distributions of neurons sensitive to acetylcholine, noradrenaline and dopamine in the dorsolateral prefrontal cortex of the monkey. Sawaguchi T, et al. **Neurosci Res** 1985 Apr;2(4):255-73

Selective neonatal depletion of dopamine has no effect on medial prefrontal cortex self-stimulation in the rat. Umemoto M, et al. **Neurosci Res** 1984 Oct;1(5):295-307

New dopaminergic terminal fields in the motor, visual (area 18b) and retrosplenial cortex in the young and adult rat. Immunocytochemical and catecholamine histochemical analyses. Berger B, et al. **Neuroscience** 1985 Aug;15(4):983-98

The effects of MIF-I, beta-endorphin and alpha-MSH on d-amphetamine induced paradoxical behavioral thermoregulation: possible involvement of the dopaminergic system. Yehuda S, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):189-92

Involvement of dopamine in the aversive stimulus properties of cocaine in rats. Hunt T, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):945-8

Central serotonin neurones in avoidance learning: interactions with noradrenaline and dopamine neurones. Ogren SO. **Pharmacol Biochem Behav** 1985 Jul;23(1):107-23

Cholecystokinin potentiates dopamine-mediated behaviors in the nucleus accumbens, a site of CCK-DA co-existence. Crawley JN. **Psychopharmacol Bull** 1985;21(3):523-7

Persistent effects of amphetamine, p-chloroamphetamine, and related compounds on central dopamine and serotonin neurons in rodents. Fuller RW. **Psychopharmacol Bull** 1985;21(3):528-32

Prolonged antidopaminergic actions of single doses of butyrophenones in the rat. Campbell A, et al. **Psychopharmacology (Berlin)** 1985; 87(2):161-6

Dopamine agonist action in mesolimbic, cortical and extrapyramidal areas to modify spontaneous climbing behaviour of the mouse. Costall B, et al. **Psychopharmacology (Berlin)** 1985;86(4):452-7

Production and excretion of dopamine by the isolated perfused rat kidney. Adam WR, et al. **Renal Physiol** 1985;8(3):150-8

Cocaine blocks the dopamine depletion induced by MPTP. Mayer RA, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jul;49(1):145-8

Responsiveness and receptive field size of carp horizontal cells are reduced by prolonged darkness and dopamine. Mangel SC, et al. **Science** 1985 Sep 13;229(4718):1107-9

Effects of dopamine and substance P infusion on gastric acid secretion in Pavlov and Heidenhain pouched dogs. Ogoshi K, et al. **Tokai J Exp Clin Med** 1984 Aug;9(3):183-90

[Effect of dopaminergic pharmacological agents on thyrotropic hormone secretion by the hypophysis when stimulated with thyrotropin-releasing hormone] Boiadzhieva N, et al. **Eksp Med Morfol** 1985;24(1):29-32 (Eng. Abstr.) **(Bul)**

[Lack of effect of aging on dopaminergic inhibition of aldosterone and prolactin increase] Preis P, et al. **Z Gerontol** 1985 Jul-Aug; 18(4):241-3 (Eng. Abstr.) **(Ger)**

[Regulation of dopamine release through the system of presynaptic receptors] Nowak JZ. **Folia Med Cracov** 1984;25(3-4):287-96 (22 ref.) (Eng. Abstr.) **(Pol)**

[Identification of dopaminergic vesicles in the electron-microscopic picture of the compact layer of the substantia nigra in the rat] Dydyk L, et al. **Neuropatol Pol** 1985;23(1):145-65 (Eng. Abstr.) **(Pol)**

[Dopaminergic receptor activity and the evolution of schizophrenia] Fodoreanu L. **Rev Med Interna [Neurol Psihiatr]** 1985 Apr-Jun; 30(2):131-4 (15 ref.) **(Rum)**

[Role of the kallikrein-kinin system and prostaglandins in the action of dopamine on blood flow and sodium transport in the rat kidney] Kuz'min OB, et al. **Fiziol Zh SSSR** 1985 May;71(5):619-24 (Eng. Abstr.) **(Rus)**

[Action of noradrenaline and dopamine on the pacemaker cells of the normal rat sinus node and in pharmacological sympathectomy] Sutiagin PV, et al. **Kardiologiia** 1985 May;25(5):88-93 (Eng. Abstr.) **(Rus)**

[Level of dopamine in structures of the nigro-striatal and mesolimbic systems of the brain in experimental pathology of higher nervous activity in the rat] Saul'skaia NB. **Zh Vyssh Nerv Deiat** 1985 May-Jun; 35(3):561-4 (Eng. Abstr.) **(Rus)**

[Brain levels of dopamine during the estrous cycle in the rat] Lerdo de Tejada A, et al. **Gac Med Mex** 1985 May-Jun;121(5-6):185-7 (Eng. Abstr.) **(Spa)**

DOPAMINE BETA-HYDROXYLASE

Genes for neurotransmitter synthesis, storage, and uptake. Joh TH, et al. **Fed Proc** 1985 Sep;44(12):2773-9

Dopamine-beta-hydroxylase-like immunoreactive neurons in two insect species, Calliphora erythrocephala and Periplaneta americana. Klemm N, et al. **Histochemistry** 1985;83(2):159-64

1-DOPA decarboxylase and dopamine-beta-hydroxylase isolated from sympathetic splenic nerves estimated by sodium dodecyl sulphate polyacrylamide gel electrophoresis with and without mercaptoethanol. Husseini HS, et al. **J Chromatogr** 1985 Jul 19;329(2):300-6

Characterization of the subunit structure of dopamine beta-hydroxylase by anion-exchange high-performance liquid chromatography. Speedie MK, et al. **J Chromatogr** 1985 Jun 26;327:351-7

Dopamine-beta-hydroxylase inhibition acutely stimulates rats hypothalamic noradrenaline and dopamine neuronal activity as assessed from metabolic ratios and circulating glucose and ACTH responses. Smythe GA, et al. **Life Sci** 1985 Sep 2;37(9):841-7

[Dopamine beta-hydroxylase activity in the plasma of women as an indicator of perioperative stress] Zrubek H, et al. **Ginekol Pol** 1984 Nov;55(11):859-62 (Eng. Abstr.) **(Pol)**

DOXEPIN

Doxepin plasma concentrations in clinical practice. Could there be a pharmacokinetic explanation for low concentrations? Joyce PR, et al. **Clin Pharmacokinet** 1985 Jul-Aug;10(4):365-70

Cimetidine-doxepin interaction. Brown MA, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):245-7

[Effect of antidepressive drugs and histamine H1 receptor blockaders on histamine level in rat brain] Zawilska J, et al. **Folia Med Cracov** 1984; 25(3-4):297-306 (Eng. Abstr.) **(Pol)**

ELECTROCONVULSIVE THERAPY

A 'gratuitous' conclusion on ECT [letter] Fink M. **Am J Psychiatry** 1985 Sep;142(9):1129-30

MHPG, ECT, and depression [letter] McDougle CJ, et al. **Biol Psychiatry** 1985 Aug;20(8):927

Effect of L-tryptophan on electroconvulsive therapy seizure time. Price WA, et al. **J Nerv Ment Dis** 1985 Oct;173(10):636-8

Electroconvulsive therapy in 1985--a review. Varghese FT, et al. **Med J Aust** 1985 Sep 2;143(5):192-6 (40 ref.)

A controlled study of cellular immune function in affective disorders before and during somatic therapy. Albrecht J, et al. **Psychiatry Res** 1985 Jul;15(3):185-93

ELECTROENCEPHALOGRAPHY

Electroencephalographic studies of psychopharmaca in Czechoslovakia. An overview. Mrňa B. **Acta Univ Palacki Olomuc Fac Med** 1985; 108:289-94

Effects of intracerebral morphine and enkephalins on the caudate-EEG spindle burst. Kamata K, et al. **Arch Int Pharmacodyn Ther** 1985 May; 275(1):68-77

Catecholamine regulation of neocortical spindling in DBA/2 mice. Ryan LJ. **Behav Brain Res** 1985 Aug;16(2-3):103-15

Topographic EEG changes with benzodiazepine administration in generalized anxiety disorder. Buchsbaum MS, et al. **Biol Psychiatry** 1985 Aug;20(8):832-42

Behavioral and eegraphic changes induced by dopaminergic antidepressants in rabbits. Bo P, et al. **Farmaco [Sci]** 1985 Aug; 40(8):608-16

Delineation of pharmacopsychological effects by means of endogenous event-related brain potentials: an exemplification with flupentixol. Rösler F, et al. **Neuropsychobiology** 1985;13(1-2):81-92

Information processing components of the auditory event related potential are reduced by cocaine. Herning RI, et al. **Psychopharmacology (Berlin)** 1985;87(2):178-85

The effect of methylphenidate on information processing. Naylor H, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):90-5

[The effect of nootropic substances on fluctuations in vigilance tonus in postinjury pseudoneurasthenia. EEG study] Strnad P, et al. **Cesk Neurol Neurochir** 1985 Jul;48(4):235-9 (Eng. Abstr.) **(Cze)**

[The effect of propranolol on the pentetrazole-induced spindle activity in the EEG of the rat] Lasek R. **Pharmazie** 1985 May;40(5):364 **(Ger)**

[Functional differentiation of the theta-rhythm of the hippocampus in the cat] Melikov EM. **Zh Vyssh Nerv Deiat** 1985 May-Jun; 35(3):457-64 (Eng. Abstr.) **(Rus)**

ELECTROLYTES

[Adaptation of distal tubular segments to changes in electrolyte metabolism] Kaissling B, et al. **Acta Histochem [Suppl] (Jena)** 1985; 31:185-91 **(Ger)**

ELECTROSHOCK

Involvement of benzodiazepine recognition sites in the foot shock-induced decrease of low affinity GABA receptors in the rat cerebral cortex. Concas A, et al. **Brain Res** 1985 Aug 19;341(1):50-6

DSP-4 lesioning prevents the enhancement of dopamine and 5-hydroxytryptamine mediated behavioural changes by repeated electroconvulsive shock. Heal DJ, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):117-21

Upregulation of gamma-aminobutyric acid (GABA) B binding sites in rat frontal cortex: a common action of repeated administration of different classes of antidepressants and electroshock. Lloyd KG, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):191-9

Presynaptic serotonin receptor-mediated response in mice attenuated by antidepressant drugs and electroconvulsive shock. Goodwin GM, et al. **Nature** 1985 Oct 10-16;317(6037):531-3

The role of central noradrenergic neurons in electroconvulsive shock-induced muricide inhibition in olfactory bulbectomized rats. Liou SY, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):65-70

[The anticonvulsant effect of propranolol in maximal electroshock in sub chronic applications] Lasek R. **Pharmazie** 1985 Jun;40(6):430 (Ger)

EMOTIONS

The participation of serotoninergic system in the regulation of emotional-defensive behavior evoked by intrahypothalamic carbachol injections in the cat. Gołebiewski H, et al. **Acta Neurobiol Exp (Warsz)** 1985;45(1-2):25-36

A controlled trial of social intervention in the families of schizophrenic patients: two year follow-up. Leff J, et al. **Br J Psychiatry** 1985 Jun; 146:594-600

The discriminative stimulus and subjective effects of d-amphetamine in humans. Chait LD, et al. **Psychopharmacology (Berlin)** 1985; 86(3):307-12

ENDORPHINS

Cell types of the pars distalis of the hedgehog (Erinaceus europaeus L.) adenohypophysis: cytological, immunocytochemical and ultrastructural studies. 3. Opiocorticomelanotropic cells. Girod C, et al. **Acta Anat (Basel)** 1985;123(1):67-71

Effects of extracorporeal circulation on plasma beta-endorphin-like-immunoreactivity in children. Yamashita M, et al. **Agressologie** 1985 Mar;26(3):267-9

Conversion and inactivation of opioid peptides by rabbit brain endo-oligopeptidase A. Camargo AC, et al. **Biochem Biophys Res Commun** 1985 Jul 31;130(2):932-8

Neuropeptide processing by single-step cleavage: conversion of leumorphin (dynorphin B-29) to dynorphin B. Devi L, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1168-76

Radioimmunoassay for beta-endorphin (1-18), a novel pituitary peptide derived from proopiomelanocortin. Vuolteenaho O. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1226-32

Rapid antidepressant activity of destyr gamma endorphin: correlation with urinary melatonin. Chazot G, et al. **Biol Psychiatry** 1985 Sep; 20(9):1026-30

Characterization of proenkephalin B-derived opioid peptides in the human hypothalamo-neurohypophyseal axis. Arendt RM, et al. **Brain Res** 1985 Oct 21;345(2):230-7

Light and electron microscopic immunocytochemistry of beta-endorphin/beta-LPH-like immunoreactive neurons in the arcuate nucleus and surrounding areas of the rat hypothalamus. Ibata Y, et al. **Brain Res** 1985 Aug 26;341(2):233-42

Release of immunoreactive Met-enkephalin from the spinal cord by intraventricular beta-endorphin but not morphine in anesthetized rats. Tseng LF, et al. **Brain Res** 1985 Sep 16;343(1):60-9

Proopiomelanocortin-derived peptides in the immune system. Blalock JE. **Clin Endocrinol (Oxf)** 1985 Jun;22(6):823-7 (15 ref.)

In vivo and in vitro effects of angiotensin II on the release of beta-endorphin-like immunoreactivity. Matsumura M, et al. **Endocrinol Jpn** 1985 Apr;32(2):233-40

Evidence that beta-endorphin binds to specific receptors in rat peripheral tissues and stimulates the adenylate cyclase-adenosine 3',5'-monophosphate system. Dave JR, et al. **Endocrinology** 1985 Oct; 117(4):1389-96

The effect of various corticotropin-releasing factor trains on the release of adrenocorticotropin, beta-endorphin, and beta-lipotropin from perifused ovine pituitary cells. Evans MJ, et al. **Endocrinology** 1985 Sep;117(3):893-9

Evidence that a benzodiazepine receptor mechanism regulates the secretion of pituitary beta-endorphin in rats. Maiewski SF, et al. **Endocrinology** 1985 Aug;117(2):474-80

Opioid peptides rapidly stimulate superoxide production by human polymorphonuclear leukocytes and macrophages. Sharp BM, et al. **Endocrinology** 1985 Aug;117(2):793-5

Novel opioid peptides derived from mitochondrial cytochrome b: cytochrophins. Brantl V, et al. **Eur J Pharmacol** 1985 May 8; 111(2):293-4

beta-Endorphin and ACTH related peptides in primary cultures of rat anterior pituitary cells: evidence for different intracellular pools. Ham J, et al. **FEBS Lett** 1985 Oct 14;190(2):253-8

Plasma beta-endorphin and the menstrual cycle. Laatikainen T, et al. **Fertil Steril** 1985 Aug;44(2):206-9

Stress-induced elevation of plasma alpha-MSH and endorphin in brown trout, Salmo trutta L. Sumpter JP, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):257-65

Lack of beta-endorphin plasma level rise in oxytocin-induced labor. Genazzani AR, et al. **Gynecol Obstet Invest** 1985;19(3):130-4

Investigation of beta-endorphin and adrenocorticotropic hormone in placenta, amniotic membrane and umbilical cord using an immunoperoxidase technique. Reinthaller A, et al. **Gynecol Obstet Invest** 1985;19(3):135-8

Localization of dynorphin B-like and alpha-neoendorphin-like immunoreactivities in the guinea pig organ of Corti. Altschuler RA, et al. **Hear Res** 1985 Mar;17(3):249-58

Beta-endorphin. Synthesis and biological activity of analogs with disulfide bridges. Blake J, et al. **Int J Pept Protein Res** 1985 Jun;25(6):575-9

Beta-endorphin does not protect alkylation of opiate receptor by N-ethylmaleimide. Westphal M, et al. **Int J Pept Protein Res** 1985 Apr; 25(4):403-7

Isolation of a specific mu-opiate receptor peptide, morphiceptin, from an enzymatic digest of milk proteins. Chang KJ, et al. **J Biol Chem** 1985 Aug 15;260(17):9706-12

Covalent labeling of opioid receptors with radioiodinated human beta-endorphin. Identification of binding site subunit. Howard AD, et al. **J Biol Chem** 1985 Sep 5;260(19):10833-9

Opioid peptides in human adrenal: partial characterization and presence of adrenal peptide E. Boarder MR, et al. **J Clin Endocrinol Metab** 1985 Oct;61(4):658-65

Inhibition by prostaglandin E2 of the release of vasopressin and beta-endorphin from rat pituitary neurointermediate lobe or medial basal hypothalamus in vitro. Knepel W, et al. **J Endocrinol** 1985 Aug; 106(2):189-95

Novel opioid peptide amidorphin: characterization and distribution of amidorphin-like immunoreactivity in bovine, ovine, and porcine brain, pituitary, and adrenal medulla. Liebisch DC, et al. **J Neurochem** 1985 Nov;45(5):1495-503

Isolation and characterization of an endogenous C-terminal fragment of the alpha-neo-endorphin/dynorphin precursor from bovine caudate nucleus. Evans CJ, et al. **J Neurosci** 1985 Jul;5(7):1803-7

Diuresis and suppression of vasopressin by kappa opioids: comparison with mu and delta opioids and clonidine. Leander JD, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):463-9

On the potassium conductance increased by opioids in rat locus coeruleus neurones. North RA, et al. **J Physiol (Lond)** 1985 Jul;364:265-80

Binding of radioiodinated human beta-endorphin to serum proteins from rats and humans, determined by several methods. Sato H, et al. **Life Sci** 1985 Oct 7;37(14):1309-18

Release of immunoreactive beta-endorphin in vitro from pituitaries of young and old male rats. Forman LJ, et al. **Neurobiol Aging** 1985 Summer;6(2):101-5

Effects of endogenous opioid peptides and opiates on luteinizing hormone and prolactin secretion in ovariectomized rats. Leadem CA, et al. **Neuroendocrinology** 1985 Oct;41(4):342-52

In vivo and in vitro effects of bradykinin on the release of beta-endorphin-like immunoreactivity. Matsumura M, et al. **Neuroendocrinology** 1985 Aug;41(2):101-6

Pituitary secretion of growth hormone in response to opioid peptides and opiates is mediated through growth hormone-releasing factor. Wehrenberg WB, et al. **Neuroendocrinology** 1985 Jul;41(1):13-6

Beta-endorphin suppression of acute morphine abstinence in morphine dependent monkeys: effective given intraventricularly but ineffective given intravenously. Domino EF, et al. **Neuropeptides** 1985 Jul; 6(4):343-50

Long-term haloperidol treatment elevates beta-endorphin levels in the intermediate pituitary but not in rat brain. Millington WR, et al. **Neuropeptides** 1985 Jul;6(4):365-72

Dopaminergic agents differentially alter beta-endorphin processing patterns in the rat pituitary neurointermediate lobe. Autelitano DJ, et al. **Neurosci Lett** 1985 Aug 16;59(1):141-6

Effects of branched-chain amino acids on beta-endorphin in the pituitary of the rat. Cobert BJ, et al. **Neurosci Lett** 1985 Aug 5;58(3):339-42

Presence of immunoreactive alpha-melanotropin and beta-endorphin in spinal motoneurones of the dystrophic mouse. Haynes LW, et al. **Neurosci Lett** 1985 Jul 4;58(1):13-8

Prodynorphin opioid peptides in small somatosensory primary afferents of guinea pig. Weihe E, et al. **Neurosci Lett** 1985 Aug 5; 58(3):347-52

Causal links between plasma and CSF endorphin levels in stress: vector-ARMA analysis. Carr DB, et al. **Peptides (Fayetteville)** 1985; 6 Suppl 1:5-10

The effects of MIF-I, beta-endorphin and alpha-MSH on d-amphetamine induced paradoxical behavioral thermoregulation: possible involvement of the dopaminergic system. Yehuda S, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):189–92

Diclofenac and pirprofen modify pituitary and hypothalamic beta–endorphin concentrations. Sacerdote P, et al. **Pharmacol Res Commun** 1985 Aug;17(8):679–84

Beta–casomorphin affects fast and slow action potentials in ventricular myocardium. Nilius B, et al. **Pharmazie** 1985 Jun;40(6):428–9

Morphine and other opiates from beef brain and adrenal. Goldstein A, et al. **Proc Natl Acad Sci USA** 1985 Aug;82(15):5203–7

The Wellcome Foundation lecture, 1982. Opioid Peptides and their Receptors. Kosterlitz HW. **Proc R Soc Lond [Biol]** 1985 Jul 22; 225(1238):27–40 (48 ref.)

Dexamethasone suppresses beta–endorphin in humans. Krantz DE, et al. **Psychoneuroendocrinology** 1985;10(2):211–4

Influence of early beta–endorphin treatment on the behavior and reaction to beta–endorphin in the adult male rat. Meyerson BJ. **Psychoneuroendocrinology** 1985;10(2):135–47

Opioid peptides in the adrenal pituitary axis. Evans CJ, et al. **Psychopharmacol Bull** 1985;21(3):466–71

The Ying–Yang hypothesis of opioid peptide immunomodulation. Plotnikoff NP. **Psychopharmacol Bull** 1985;21(3):489

Current concepts in premenstrual syndrome. Ullman LE. **RI Med J** 1985 Jun;68(6):269–72

Effects of some opiates and vasoactive intestinal peptide (VIP) on duodenal surface epithelial bicarbonate secretion in the rat. Flemström G, et al. **Scand J Gastroenterol [Suppl]** 1985;110:49–53

[Effect of hypoxia on the content of endogenous opioid peptides and cyclic nucleotides in the rat brain] Fujita S, et al. **Masui** 1985 Jun; 34(6):767–72 (Eng. Abstr.) **(Jpn)**

[Distribution of alpha–, beta– and gamma–endorphins in the forebrain and diencephalon of the rat brain (immunohistochemical study)] Makarenko IG, et al. **Arkh Anat Gistol Embriol** 1985 Jul;89(7):10–8 (Eng. Abstr.) **(Rus)**

[ACTH, corticosterone and beta–endorphin in the blood plasma of rats under prolonged immobilization stress] Kiiatkin EA, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):157–60 (Eng. Abstr.) **(Rus)**

[Biosynthesis of pro–opiomelanocortin and secretion of its fragments by cultured bone marrow cells of mice] Dmitriev AD, et al. **Dokl Akad Nauk SSSR** 1985 May–Jun;282(1):199–202 **(Rus)**

[Effect of opioid peptides on nervous tissue in vitro] Il'inskii OB, et al. **Neirofiziologiia** 1985;17(4):550–7 (Eng. Abstr.) **(Rus)**

ENKEPHALIN, LEUCINE

Hemorrhagic shock and the central vasopressin and opioid peptide system of rats. Feuerstein G, et al. **Am J Physiol** 1985 Sep; 249(3 Pt 1):E244–50

Localization of substance P–like, leucine–enkephalin–like, methionine–enkephalin–like, and FMRFamide–like immunoreactivity in the eyestalk of the fiddler crab, Uca pugilator. Fingerman M, et al. **Cell Tissue Res** 1985;241(3):473–7

On the origin of Leu–enkephalin and Met–enkephalin in the rat neurohypophysis. Zamir N. **Endocrinology** 1985 Oct;117(4):1687–92

Cyanogen bromide cleavage of methionine residues as a control method for enkephalin immunocytochemistry. Jirikowski G. **Histochemistry** 1985;83(1):93–5

Reduced mechanical activity of perfused rat heart following morphine or enkephalin peptides administration. Clò C, et al. **Life Sci** 1985 Oct 7;37(14):1327–33

Sulfonic acid enkephalin: binding specificity to rat brain opiate receptors. Martin JL, et al. **Neuropeptides** 1985 Jul;6(4):293–302

Enkephalin pseudopeptides: resistance to in vitro proteolytic degradation afforded by amide bond replacements extends to remote sites. Benovitz DE, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):257–61

Central effects of mu, delta, and kappa receptor agonists in hemorrhagic shock. Feuerstein G, et al. **Peptides (Fayetteville)** 1985; 6 Suppl 1:11–3

[Synthesis of leucine– and methionine–enkephalin using papain] Zapevalova NP, et al. **Bioorg Khim** 1985 Jun;11(6):733–7 (Eng. Abstr.) **(Rus)**

[Mechanism of the antistressor effect of D–Ala(2)–Leu(5)–Arg(6)–enkephalin] Lishmanov IuB, et al. **Biull Eksp Biol Med** 1985 Sep;100(9):268–70 (Eng. Abstr.) **(Rus)**

[Effect of leu–enkephalin and the delta–sleep–inducing peptide, M (DSIP), on endogenous noradrenaline release by brain synaptosomes in the rat] Rozhanets VV, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):199–201 (Eng. Abstr.) **(Rus)**

[Differential method of analyzing ligand complex formation with binding centers. The detection of the superhigh–affinity binding centers of opiate ligands] Zaitsev SV, et al. **Dokl Akad Nauk SSSR** 1985; 281(3):727–31 **(Rus)**

[Effect of enkephalins on the plasticity of pond snail] Verbnyi IaI. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):306–13 (Eng. Abstr.) **(Rus)**

ENKEPHALIN, METHIONINE

Pharmacological analysis of the mechanism of action for colonic contraction induced by neurotensin, substance P and methionine–enkephalin. Hellström PM. **Acta Physiol Scand** 1985 Sep; 125(1):13–24

ATP–dependent [3H]Met–enkephalin uptake by bovine adrenal chromaffin granule membrane. Takeda F, et al. **Brain Res** 1985 Oct 7;344(2):220–6

Release of immunoreactive Met–enkephalin from the spinal cord by intraventricular beta–endorphin but not morphine in anesthetized rats. Tseng LF, et al. **Brain Res** 1985 Sep 16;343(1):60–9

Localization of substance P–like, leucine–enkephalin–like, methionine–enkephalin–like, and FMRFamide–like immunoreactivity in the eyestalk of the fiddler crab, Uca pugilator. Fingerman M, et al. **Cell Tissue Res** 1985;241(3):473–7

On the origin of Leu–enkephalin and Met–enkephalin in the rat neurohypophysis. Zamir N. **Endocrinology** 1985 Oct;117(4):1687–92

Cyanogen bromide cleavage of methionine residues as a control method for enkephalin immunocytochemistry. Jirikowski G. **Histochemistry** 1985;83(1):93–5

Immunocytochemical localization of a methionine–enkephalin–resembling neuropeptide in the central nervous system of the American cockroach, Periplaneta americana L. Verhaert P, et al. **J Comp Neurol** 1985 Sep 1;239(1):54–61

Intragranular colocalization of immunoreactive methionine–enkephalin and oxytocin within the nerve terminals in the posterior pituitary. Adachi T, et al. **J Histochem Cytochem** 1985 Sep;33(9):891–9

Localization of Met–enkephalin–Arg6–Gly7–Leu8–like immunoreactivity in the gastrointestinal tract of rat and pig. Nihei K, et al. **J Histochem Cytochem** 1985 Oct;33(10):1001–6

A potentiometric and spectroscopic study of the proton and copper(II) complexes of methionine enkephalin and some related ligands. Formicka–Kozlowska G, et al. **J Inorg Biochem** 1985 Aug; 24(4):299–307

Ventilatory response to intravenous methionine enkephalin in awake dogs. Evanich MJ, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):677–80

Cyclooxygenase inhibitors affect Met–enkephalin– and acetylcholine–stimulated motility of the isolated rat colon. Scheurer U, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):742–6

Reduced mechanical activity of perfused rat heart following morphine or enkephalin peptides administration. Clò C, et al. **Life Sci** 1985 Oct 7;37(14):1327–33

Mechanism of methionine–enkephalin modulation of glutamatergic transmission in the rat striatum. Kuznetsov VI, et al. **Neurosci Lett** 1985 Jun 12;57(2):143–6

Methionine–enkephalin–Arg6–Gly7–Leu8–immunoreactive nerve fibers and cell bodies in lumbar paravertebral ganglia and the celiac–superior mesenteric ganglion complex of the rat: an immunohistochemical study. Shimosegawa T, et al. **Neurosci Lett** 1985 Jun 12;57(2):169–74

The proenkephalin A fragment metorphamide shows supraspinal and spinal opioid activity in vivo. Dray A, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):217–21

Pro–enkephalin peptides possessing Met–enkephalin–Arg6–Gly7–Leu8–immunoreactivity in rat CSF, striatum and adrenal gland. Jackson S, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):169–78

[Met–enkephalin–Arg–Gly–Leu–like immunoreactivity–containing nerve fibers and cell bodies in the abdominal sympathetic ganglia of the rat—an immunohistochemical study] Shimosegawa T, et al. **Nippon Naibunpi Gakkai Zasshi** 1985 May 20;61(5):581–91 (Eng. Abstr.) **(Jpn)**

[Synthesis of leucine– and methionine–enkephalin using papain] Zapevalova NP, et al. **Bioorg Khim** 1985 Jun;11(6):733–7 (Eng. Abstr.) **(Rus)**

[Mechanism of the modulating effect of met–enkephalin on glutamatergic synaptic transmission] Kuznetsov VI, et al. **Dokl Akad Nauk SSSR** 1985; 282(2):456–9 **(Rus)**

[Effect of enkephalins on the plasticity of pond snail] Verbnyi IaI. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):306–13 (Eng. Abstr.) **(Rus)**

ENKEPHALINS

Sodium–induced release of enkephalins from bovine chromaffin granules in vitro. Uvnäs B, et al. **Acta Physiol Scand** 1985 Aug;124(4):629–30

Myenteric enkephalin neurons around the laser–photocoagulation necrosis: an immunocytochemical investigation in the guinea pig jejunum and proximal colon. Kobayashi S, et al. **Arch Histol Jpn** 1985 Apr;48(2):239–54

Effects of intracerebral morphine and enkephalins on the caudate–EEG spindle burst. Kamata K, et al. **Arch Int Pharmacodyn Ther** 1985 May; 275(1):68–77

Neuropeptide processing by single–step cleavage: conversion of leumorphin (dynorphin B–29) to dynorphin B. Devi L, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1168–76

Endopeptidase in human cerebrospinal fluid which cleaves proenkephalin B opioid peptides at consecutive basic amino acids. Nyberg F, et al. **Biochem Biophys Res Commun** 1985 Sep 30;131(3):1069–74

Conformation of cyclic analogs of enkephalin. III. Effect of varying ring size. Hall D, et al. **Biopolymers** 1985 Jun;24(6):935–45

Prediction of the native conformation of a polypeptide by a statistical-mechanical procedure. I. Backbone structure of enkephalin. Paine GH, et al. **Biopolymers** 1985 Aug;24(8):1391–436

Use of buildup and energy-minimization procedures to compute low-energy structures of the backbone of enkephalin. Vásquez M, et al. **Biopolymers** 1985 Aug;24(8):1437–47

Ontogenesis of proenkephalin products in rat striatum and the inhibitory effects of low-level lead exposure. Bailey C, et al. **Brain Res** 1985 Sep; 354(1):75–9

Opposing effects of oxytocin and of a mu-receptor agonistic opioid peptide on the same class of non-pyramidal neurones in rat hippocampus. Raggenbass M, et al. **Brain Res** 1985 Oct 7; 344(2):392–6

The effect of some enkephalins on calcitonin secretion. Gozariu L, et al. **Endocrinologie** 1985 Jul–Sep;23(3):201–4

The proenkephalin A fragment, peptide E: central processing and CNS activity in vivo. Davis TP, et al. **Eur J Pharmacol** 1985 May 8; 111(2):177–83

Chronic antidepressant treatment increases enkephalin levels in n. accumbens and striatum of the rat. De Felipe MC, et al. **Eur J Pharmacol** 1985 May 28;112(1):119–22

Increased affinity and selectivity of enkephalin tripeptide (Tyr–D–Ala–Gly) dimers. Lutz RA, et al. **Eur J Pharmacol** 1985 May 8;111(2):257–61

Detection of the tripeptide Tyr–Gly–Gly, a putative enkephalin metabolite in brain, using a sensitive radioimmunoassay. Llorens-Cortes C, et al. **FEBS Lett** 1985 Sep 23;189(2):325–8

Synthesis and biological activity of linear and cyclic enkephalins modified at the Gly3–Phe4 amide bond. Richman SJ, et al. **Int J Pept Protein Res** 1985 Jun;25(6):648–62

Synthesis and biological evaluation of phosphonamidate peptide inhibitors of enkephalinase and angiotensin-converting enzyme. Elliott RL, et al. **J Med Chem** 1985 Sep;28(9):1208–16

Presence and ontogeny of enkephalin and substance P in the chick ciliary ganglion. White JD, et al. **J Neurochem** 1985 Oct;45(4):1319–22

Isolation and characterization of an endogenous C-terminal fragment of the alpha-neo-endorphin/dynorphin precursor from bovine caudate nucleus. Evans CJ, et al. **J Neurosci** 1985 Jul;5(7):1803–7

Peptidases that terminate the action of enkephalins. Consideration of physiological importance for amino-, carboxy-, endo-, and pseudoenkephalinase. Dua AK, et al. **Life Sci** 1985 Sep 16; 37(11):985–92 (70 ref.)

Use of mRNA hybridization and radioimmunoassay to study mechanisms of drug-induced accumulation of enkephalins in rat brain structures. Mocchetti I, et al. **Mol Pharmacol** 1985 Jul;28(1):86–91

Effects of endogenous opioid peptides and opiates on luteinizing hormone and prolactin secretion in ovariectomized rats. Leadem CA, et al. **Neuroendocrinology** 1985 Oct;41(4):342–52

Release of proenkephalin-derived opioid peptides from rat striatum in vitro and their rapid degradation. Patey G, et al. **Neuroscience** 1985 Aug;15(4):1035–44

Ontogeny and regional distribution of proenkephalin- and prodynorphin-derived peptides and opioid receptors in rat hippocampus. Zamir N, et al. **Neuroscience** 1985 Aug;15(4):1025–34

Central effects of mu, delta, and kappa receptor agonists in hemorrhagic shock. Feuerstein G, et al. **Peptides (Fayetteville)** 1985; 6 Suppl 1:11–3

Changes in plasma proenkephalin peptide F and catecholamine levels during graded exercise in men. Kraemer WJ, et al. **Proc Natl Acad Sci USA** 1985 Sep;82(18):6349–51

Proenkephalin and enkephalin metabolism by rat brain cathepsin B: conversion, inactivation, and suppression by an endogenous inhibitor. Marks N, et al. **Prog Clin Biol Res** 1985;180:247–9

[The spinal enkephalinergic and serotoninergic systems in the control of transmission of nociceptive messages] Cesselin F, et al. **J Pharmacol** 1985;16 Suppl 1:119–37 (70 ref.) (Eng. Abstr.) **(Fre)**

[Effect of gamma irradiation on brain enkephalin hydrolase activity in the rat] Gengin MT, et al. **Radiobiologiia** 1985 May–Jun;25(3):394–7 (Eng. Abstr.) **(Rus)**

[Effect of a cyclic analog of enkephalin on learning and memory in the mouse] Getsova VM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug; 35(4):710–7 (Eng. Abstr.) **(Rus)**

EPINEPHRINE

Beta receptors in peripheral mononuclear cells increase acutely during exercise. Burman KD, et al. **Acta Endocrinol (Copenh)** 1985 Aug; 109(4):563–8

Central hyperglycaemic effect of adrenaline and carbachol. Iguchi A, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):440–5

Effect of the rate of blood loss on the plasma catecholamine response. Tárnoky K, et al. **Acta Physiol Hung** 1985;66(2):143–53

Central nervous system actions of somatostatin-related peptides. Brown MR, et al. **Adv Exp Med Biol** 1985;188:217–28

Blood flow in the renal portal circulation of the turkey: effect of epinephrine. Palmore WP, et al. **Am J Vet Res** 1985 Jul; 46(7):1589–92

Beneficial effect of epinephrine infusion on cerebral and myocardial blood flows during CPR. Koehler RC, et al. **Ann Emerg Med** 1985 Aug; 14(8):744–9

Effects of prolonged intravenous infusions of adrenaline on glucose utilization, plasma metabolites, hormones and milk production in lactating sheep. Leenanuruksa D, et al. **Aust J Biol Sci** 1985; 38(2):197–208

Stress, catecholamines, and sleep. Harrison GA. **Aviat Space Environ Med** 1985 Jul;56(7):651–3

Adrenergic-agonist-induced Ca2+ fluxes in rat parotid cells are not Na+-dependent. Helman J, et al. **Biochem J** 1985 Sep 1; 230(2):313–20

Release of endogenous brain epinephrine by the calcium ionophores X537A and A23187. Liang NY, et al. **Brain Res** 1985 Aug 26; 341(2):297–302

Increased plasma noradrenaline during low dose adrenaline infusion in resting man and during sympathetic stimulation. Musgrave IF, et al. **Clin Exp Pharmacol Physiol** 1985 May–Jun;12(3):285–9

Beta-adrenoceptor responsiveness and plasma catecholamines as determinants of cardiovascular reactivity to mental stress. Eisenhofer G, et al. **Clin Sci** 1985 Oct;69(4):483–92

The development of a homologous teleost insulin radioimmunoassay and its use in the study of adrenaline on insulin secretion from isolated pancreatic islet tissue of the rainbow trout, Salmo gairdinerii (R.). Tilzey JF, et al. **Comp Biochem Physiol** [A] 1985;81(4):821–5

Adrenergic stimulation of adrenocortical secretion in immature fowl. Rees A, et al. **Comp Biochem Physiol** [C] 1985;81(2):387–9

Pretreatment with detergents modulates the effects of epinephrine on uveal flow and intraocular pressure. van Pinxteren PC, et al. **Curr Eye Res** 1985 Jul;4(7):783–8

Thyroid hormones in rats during long-term cold exposure and hypometabolic effect of reverse triiodothyronine on adrenaline induced thermogenesis. Vybíral S, et al. **Endocrinol Exp (Bratisl)** 1985 Sep; 19(3):179–85

Elevated catecholamines in porcine follicular fluid before ovulation. Bahr JM, et al. **Endocrinology** 1985 Aug;117(2):620–3

Examination of the effects of epinephrine, norepinephrine, and dopamine on aldosterone production in bovine glomerulosa cells in vitro. Sequeira SJ, et al. **Endocrinology** 1985 Nov;117(5):1947–52

Histopathology of the spinal cord after intrathecal cocaine, bupivacaine, lignocaine and adrenaline in the rat. Bahar M, et al. **Eur J Anaesthesiol** 1984 Sep;1(3):293–7

Plasma testosterone and catecholamine responses to physical exercise of different intensities in men. Ježová D, et al. **Eur J Appl Physiol** 1985; 54(1):62–6

Decrease in adrenaline content of various organs of the rat after 6-hydroxydopamine. Sudo A. **Eur J Pharmacol** 1985 Aug 7; 114(1):79–83

A role for adrenaline and calmodulin in modulating cyclic AMP levels during the lactogenic cycle. Muñoz A, et al. **FEBS Lett** 1985 Jul 22; 187(1):173–6

Epinephrine effect on carbohydrate metabolism in isolated and perfused catfish liver. Ottolenghi C, et al. **Gen Comp Endocrinol** 1985 Aug; 59(2):219–29

Effect of slow calcium channel blockers on the electromechanical activity of frog myocardium in the presence of epinephrine. Gendvilienė V, et al. **Gen Physiol Biophys** 1985 Aug;4(4):349–58

Iontophoresis of epinephrine isomers to rabbit eyes induced HSV-1 ocular shedding. Hill JM, et al. **Invest Ophthalmol Vis Sci** 1985 Sep; 26(9):1299–303

Effects of timolol, epinephrine, and acetazolamide on aqueous flow during sleep. Topper JE, et al. **Invest Ophthalmol Vis Sci** 1985 Oct; 26(10):1315–9

Vascular responses to intravenous catecholamines in hands and forearms with normal and with increased skin blood flow. Allen JA, et al. **Ir J Med Sci** 1985 May;154(5):178–86

The hemodynamic and plasma catecholamine responses to routine restorative dental care. Cioffi GA, et al. **J Am Dent Assoc** 1985 Jul; 111(1):67–70

Stimulation by epinephrine of the membrane transport of long chain fatty acid in the adipocyte. Abumrad NA, et al. **J Biol Chem** 1985 Aug 25; 260(18):9969–71

Haemodynamic and catecholamine responses to hypothermia in the fetal sheep in utero. Gunn TR, et al. **J Dev Physiol** 1985 Aug;7(4):241–9

Do catecholamines directly modulate the delayed plateau potassium current in frog atrium? Hume JR. **J Mol Cell Cardiol** 1985 Aug; 17(8):813–6

Autoregulation of endogenous epinephrine release via presynaptic adrenoceptors in the rat hypothalamic slice. Goshima Y, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):248–53

Free and conjugated catecholamines in digestive tissues of rats. Gaudin C, et al. **Life Sci** 1985 Oct 21;37(16):1469–74

Adrenaline and anaphylaxis [letter] Ford RM. **Med J Aust** 1985 Sep 30; 143(7):319

In support of a model bill allowing the use of insect sting kits by trained laymen. Frazier CA. **NC Med J** 1985 Jun;46(6):571–2

Serotonin coexists with epinephrine in rat adrenal medullary cells. Holzwarth MA, et al. **Neuroendocrinology** 1985 Sep;41(3):230–6

Biochemical, physical and psychological findings in patients suffering from cardiac neurosis. Gasic S, et al. **Neuropsychobiology** 1985; 13(1–2):12–6

Neuroendocrine differences between violent and non–violent parasuicides. Prasad AJ. **Neuropsychobiology** 1985;13(4):157–9

Substance P given intrathecally at the spinal T9 level increases adrenal output of adrenaline and noradrenaline in the rat. Yashpal K, et al. **Neuroscience** 1985 Jun;15(2):529–36

Mechanisms involved in the adrenaline–induced blockade of milk ejection in dairy cattle. Gorewit RC, et al. **Proc Soc Exp Biol Med** 1985 Nov; 180(2):340–7

Role of brain epinephrine neurons in the regulation of serum prolactin and luteinizing hormone release in female rats. Liang NY, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jun;48(3):459–62

Plasma adrenaline and noradrenaline during mental stress and isometric exercise in man. The role of arterial sampling. Jörgensen LS, et al. **Scand J Clin Lab Invest** 1985 Sep;45(5):447–52

Epinephrine–induced aggregation of rabbit platelets refractory to ADP. Lalau Keraly C, et al. **Thromb Haemost** 1985 Jun 24;53(3):366–71

[The effect of water structure on cyclodextrin inclusion and light sensitivity of epinephrine] Hüttenrauch R, et al. **Pharmazie** 1985 Mar; 40(3):199–200 **(Ger)**

[Individual differences in circadian response to a schedule with a 12–hour time shift––a laboratory study of oral temperature, and adrenaline and 17–OHCS excretion] Okada A, et al. **Ann Physiol Anthropol** 1984 Oct; 3(4):275–82 (Eng. Abstr.) **(Jpn)**

[Effects of epinephrine on plasma potassium; their relations with the liver] Saito Y, et al. **Masui** 1985 Apr;34(4):458–62 (Eng. Abstr.) **(Jpn)**

[Psychoneurotic disorders in puberty and the activity of the adrenergic system] Szewczyk L. **Pediatr Pol** 1985 Apr;60(4):306–11 (Eng. Abstr.) **(Pol)**

[Effect of Na+, K+ and Ca++ ions on catecholamine release in the caudal mesenteric ganglion] Reprintseva VM. **Fiziol Zh SSSR** 1985 May; 71(5):561–8 (Eng. Abstr.) **(Rus)**

[Effect of carbon dioxide baths on the content of catecholamines in the brain and processes of their inactivation] Mirzoian SA, et al. **Vopr Kurortol Fizioter Lech Fiz Kult** 1985 May–Jun;(3):16–9 (Eng. Abstr.) **(Rus)**

[Urinary excretion of epinephrine in patients on short–term and long–term corticosteroid therapy] Ješić S, et al. **Srp Arh Celok Lek** 1985 Jan; 113(1):29–40 (Eng. Abstr.) **(Scc)**

ESCAPE REACTION

[Substance P in the central mechanisms of the escape reaction] Zilov VG, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):6–8 (Eng. Abstr.) **(Rus)**

[Endogenous peptides in the organization of somato–vegetative responses to hypothalamic stimulation] Badikov VI, et al. **Fiziol Zh SSSR** 1985 Jul;71(7):840–7 (Eng. Abstr.) **(Rus)**

ESTRADIOL

Systemic and uterine responsiveness to angiotensin II and norepinephrine in estrogen–treated nonpregnant sheep. Naden RP, et al. **Am J Obstet Gynecol** 1985 Oct 15;153(4):417–25

LH response to LH–RH neonatally estrogenized male rats. Pinilla L, et al. **Andrologia** 1985 May–Jun;17(3):254–6

Pulsatile administration of gonadotropin–releasing hormone to anestrous sows: endocrine changes associated with GnRH–induced and spontaneous estrus. Armstrong JD, et al. **Biol Reprod** 1985 Sep; 33(2):375–80

Elevated catecholamines in porcine follicular fluid before ovulation. Bahr JM, et al. **Endocrinology** 1985 Aug;117(2):620–3

Effects of ovarian hormones on the concentrations of immunoreactive neuropeptide Y in discrete brain regions of the female rat: correlation with serum luteinizing hormone (LH) and median eminence LH–releasing hormone. Crowley WR, et al. **Endocrinology** 1985 Sep; 117(3):1151–5

In vivo gonadotropin–releasing hormone release and serum luteinizing hormone measurements in ovariectomized, estrogen–treated rhesus macaques. Levine JE, et al. **Endocrinology** 1985 Aug;117(2):711–21

Secretion of ovine luteinizing hormone in vitro: differential positive control by 17 beta–estradiol and a preparation of porcine ovarian inhibin. Miller WL, et al. **Endocrinology** 1985 Sep;117(3):907–11

Effect of dopamine agonists and antagonists on the binding of [3H]estradiol to its receptors in the anterior pituitary gland of male rats. Szijan I, et al. **Endocrinology** 1985 Nov;117(5):1742–8

Effect of local GABA administration on rat ovarian blood flow, and on progesterone and estradiol secretion. Erdő S, et al. **Eur J Pharmacol** 1985 May 20;111(3):397–400

Sex–specific effects of estradiol on hypothalamic noradrenaline turnover in gonadectomized rats. Hiemke C, et al. **Exp Brain Res** 1985; 59(1):68–72

Estradiol and melatonin effects on adrenal cortex of ovariectomized and pinealectomized rats. Malendowicz LK, et al. **Exp Clin Endocrinol** 1985 Jun;85(3):276–82

Clomiphene citrate can mimic the augmentative (positive) but not the depressing (negative) effect of estradiol on the LHRH–stimulated release of LH and FSH by the pituitary gland of the long–term ovariectomized rat. Schuiling GA, et al. **Experientia** 1985 Aug 15;41(8):1060–3

Antioestrogen inhibition of oestradiol–induced alterations in hypothalamic noradrenaline turnover. Hiemke C, et al. **J Endocrinol** 1985 Jul; 106(1):37–42

Time–dependent effects of oestradiol and progesterone on hypothalamic catecholamine turnover in ovariectomized rats. Hiemke C, et al. **J Endocrinol** 1985 Sep;106(3):303–9

Catechol oestradiol control of FSH–stimulated granulosa cell steroidogenesis. Hudson KE, et al. **J Endocrinol** 1985 Jul; 106(1):R1–4

Estradiol increases growth hormone secretion in rats exposed to swimming stress or reserpine treatment. Eriksson E, et al. **Life Sci** 1985 Sep 30; 37(13):1241–8

Preoptic catecholamine, GABA, and glutamate release in ovariectomized and ovariectomized estrogen–primed rats utilizing a push–pull cannula technique. Demling J, et al. **Neuroendocrinology** 1985 Sep; 41(3):212–8

Ovarian steroid regulation of pulsatile luteinizing hormone release during the interval between the mornings of diestrus 2 and proestrus in the rat. Leipheimer RE, et al. **Neuroendocrinology** 1985 Sep;41(3):252–7

Estradiol–induced LH release in juvenile female rats: nembutal blocks both the decline and the exposure of nonavailable pituitary LHRH receptor sites. Smith SS, et al. **Neuroendocrinology** 1985 Sep; 41(3):246–51

Hypothalamic monoaminergic activity and pituitary function in male rats with estrogen–induced pituitary hyperplasia. Terry LC, et al. **Neuroendocrinology** 1985 Oct;41(4):269–75

Effects of pimozide and domperidone administration on prolactin levels in neonatally estrogenized female rats. Aguilar E, et al. **Rev Esp Fisiol** 1985 Jun;41(2):183–6

[Correlation between the thyroxine, 17–beta–estradiol and luteinizing hormones in the systemic circulation and the rectal and vaginal temperature in heifers and cows after administration of cloprostenol] Elečko J, et al. **Vet Med (Praha)** 1985 May;30(5):257–66 (Eng. Abstr.) **(Slo)**

ETHOLOGY

[Discrete and continuous mathematical models of intraspecific behavior in the pharmacoethology of the mouse] Poshivalov VP, et al. **Zh Vyssh Nerv Deiat** 1985 May–Jun;35(3):487–96 (Eng. Abstr.) **(Rus)**

EXPLORATORY BEHAVIOR

A genetically controlled hippocampal transmitter system regulating exploratory behavior in mice. van Abeelen JH, et al. **J Neurogenet** 1984 Apr;1(2):153–8

The effects of compounds related to gamma–aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: choice behaviour in the T–maze. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;86(3):328–33

EXTINCTION (PSYCHOLOGY)

The abolition of the partial reinforcement extinction effect (PREE) by amphetamine. Weiner I, et al. **Psychopharmacology (Berlin)** 1985; 86(3):318–23

FACTITIOUS DISORDERS

Recognition of pseudodementia. McAllister TW. **Am Fam Physician** 1985 Oct;32(4):175–81

FEAR

Lactate–induced panic attacks: possible involvement of serotonin reuptake stimulation. Lingjaerde O. **Acta Psychiatr Scand** 1985 Aug; 72(2):206–8

Platelet monoamine oxidase activity in patients with panic disorder. Gorman J, et al. **Biol Psychiatry** 1985 Aug;20(8):852–7

Thyroid indices in panic disorder. Fishman SM, et al. **J Clin Psychiatry** 1985 Oct;46(10):432–3

Suppressant effect of REM sleep deprivation on neophobia in normal rats and in rats with selective DSP–4 induced damage of locus coeruleus neurons. Mogilnicka E, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):93–7

Effect of panic attacks on the treatment of atypical depressives. Liebowitz MR, et al. **Psychopharmacol Bull** 1985;21(3):558–61

Panic attacks in outpatients with depression: response to antidepressant treatment. Robinson DS, et al. **Psychopharmacol Bull** 1985; 21(3):562–7

Neuroendocrine abnormalities in panic disorder. Roy–Byrne PP, et al. **Psychopharmacol Bull** 1985;21(3):546–50

[Panic attacks treated with alprazolam (letter)] Andersen T. **Ugeskr Laeger** 1985 Jun 17;147(25):2014–5 **(Dan)**

FENFLURAMINE

Experimental neurotoxicity of the anorectic fenfluramine. I. A fine structural model for cerebral lysosomal storage and neuroglial reaction. Dastur DK, et al. **Acta Neuropathol (Berl)** 1985;67(1–2):142–54

Pilot study on the effects of fenfluramine on negative symptoms in twelve schizophrenic inpatients. Stahl SM, et al. **Biol Psychiatry** 1985 Oct; 20(10):1098–102

A comparison of the acute effects of dextroamphetamine and fenfluramine in depression. Ward NG, et al. **Biol Psychiatry** 1985 Oct; 20(10):1090–7

Use of mRNA hybridization and radioimmunoassay to study mechanisms of drug-induced accumulation of enkephalins in rat brain structures. Mocchetti I, et al. **Mol Pharmacol** 1985 Jul;28(1):86–91

Pharmacological studies on the serotoninergic and nonserotonin-mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L-tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283–8

Serotonin and norepinephrine-dependent effects of fenfluramine on plasma renin activity in conscious male rats. Van de Kar LD, et al. **Neuropharmacology** 1985 Jun;24(6):487–94

FK 33–824

Influence of methionine-enkephalin analogue (FK-33-824) on the secretion of pancreatic hormones. Sekiya K, et al. **Gastroenterol Jpn** 1985 Jun;20(3):252–9

Blockade of alpha 2-adrenoceptors prevents the growth hormone releasing effect of FK 33-824 in the dog. Cella SG, et al. **Horm Metab Res** 1985 Jul;17(7):379–80

Gonadal steroids deficiency and prolactin response to a met-enkephalin analog in man. Foresta C, et al. **Horm Metab Res** 1985 Jun; 17(6):319–20

FLICKER FUSION

Temazepam and the perceptual-motor performance of professional footballers. Golby J, et al. **Br J Sports Med** 1985 Jun;19(2):115–8

Evaluation of signal detection theory on the effects of psychotropic drugs on critical flicker-fusion frequency in normal subjects. MacNab MW, et al. **Psychopharmacology (Berlin)** 1985;85(4):431–5

FLUPHENAZINE

Separate and combined anxiolytic and anti-depressant treatment of mixed anxiety/depression. A double-blind, placebo controlled comparison. Sussex Clinical Trials Group. **Acta Psychiatr Scand** 1985 Jul; 72(1):81–8

Long-term depot maintenance of chronic schizophrenic out-patients: the seven year follow-up of the Medical Research Council fluphenazine/placebo trial. III. Relapse postponement or relapse prevention? The implications for long-term outcome. Curson DA, et al. **Br J Psychiatry** 1985 May;146:474–80

Long-term depot maintenance of chronic schizophrenic out-patients: the seven year follow-up of the Medical Research Council fluphenazine/placebo trial I. Course of illness, stability of diagnosis, and the role of a special maintenance clinic. Curson DA, et al. **Br J Psychiatry** 1985 May;146:464–9

Neuroleptic serum levels measured by radioreceptor assay in patients receiving intramuscular depot neuroleptics. Some preliminary findings. Turbott J, et al. **Br J Psychiatry** 1985 Apr;146:439–42

FOOD DEPRIVATION

Effects of cadmium ingestion and food restriction on energy metabolism and tissue metal concentrations in mallard ducks (Anas platyrhynchos). Di Giulio RT, et al. **Environ Res** 1985 Aug;37(2):433–44

Norepinephrine turnover in the hypothalamus of adult male rats: alteration of circadian patterns by semistarvation. Schweiger U, et al. **J Neurochem** 1985 Sep;45(3):706–9

Effects of withholding food for 0–72 h on mating, pregnancy rate and pituitary function in female rats. McClure TJ, et al. **J Reprod Fertil** 1985 May;74(1):57–64

FSH

Effect of pretreatment of long-term ovariectomized (OVX) rats with a competitive LRH antagonist on FSH release in vitro. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):481–4

Selective and/or overlapping effect of pituitary hormones (thyrotropin, gonadotropin) on serum thyroxin and testosterone level in newly hatched cockerels. Dobozy O, et al. **Acta Physiol Hung** 1985; 66(2):177–81

Plasma FSH and LH in prepubertal Booroola ewe lambs. Bindon BM, et al. **Aust J Biol Sci** 1985;38(2):215–20

A suppression of gonadotropin secretion by cortisol in castrated male rhesus monkeys (Macaca mulatta) mediated by the interruption of hypothalamic gonadotropin-releasing hormone release. Dubey AK, et al. **Biol Reprod** 1985 Sep;33(2):423–31

The effects of cycloheximide on in vitro response of Rana pipiens pituitaries to continuously superfused gonadotropin-releasing hormone. Porter DA. **Biol Reprod** 1985 Sep;33(2):393–400

Thyrotropin and gonadotropin releasing hormones (TRH and GnRH) do not alter levels of oxytocin and oxytocin does not change the response of luteinizing or follicle stimulating hormones to GnRH in humans. Amico JA, et al. **Endocr Res** 1985;11(1–2):75–85

Differential regulation of pulsatile luteinizing hormone (LH) and follicle-stimulating hormone secretion in ovariectomized rats disclosed by treatment with a LH-releasing hormone antagonist and phenobarbital. De Paolo LV. **Endocrinology** 1985 Nov; 117(5):1826–33

Identification of subpopulations of rat granulosa cells: sedimentation properties and hormonal responsiveness. Kasson BG, et al. **Endocrinology** 1985 Sep;117(3):1027–34

Corelease of dynorphin-like immunoreactivity, luteinizing hormone, and follicle-stimulating hormone from rat adenohypophysis in vitro. Knepel W, et al. **Endocrinology** 1985 Aug;117(2):481–7

Effects of glucocorticoids on responsiveness of luteinizing hormone and follicle-stimulating hormone to gonadotropin-releasing hormone by male rat pituitary cells in vitro. Suter DE, et al. **Endocrinology** 1985 Sep;117(3):855–9

Effects of glucocorticoids on secretion of luteinizing hormone and follicle-stimulating hormone by female rat pituitary cells in vitro. Suter DE, et al. **Endocrinology** 1985 Sep;117(3):849–54

Clomiphene citrate can mimic the augmentative (positive) but not the depressing (negative) effect of estradiol on the LHRH-stimulated release of LH and FSH by the pituitary gland of the long-term ovariectomized rat. Schuiling GA, et al. **Experientia** 1985 Aug 15;41(8):1060–3

Serum luteinizing hormone-releasing hormone (LH-RH) and gonadotropic hormones in men after a bolus dose of LH-RH: comparison of different doses and routes of administration. Fauser BC, et al. **Fertil Steril** 1985 Sep;44(3):384–9

Effects of chicken (Gln8)- and mammalian (Arg8)-luteinizing hormone-releasing hormones on the release of gonadotrophins in vitro and in vivo from the adenohypophysis of Japanese quail. Hattori A, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):155–61

Seasonal cycles in testicular activity, gonadotropin, and thyroxine in the painted turtle, Chrysemys picta, under natural conditions. Licht P, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):130–9

Pituitary responsiveness to superfused GnRH in two species of ranid frogs. Porter DA, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):308–15

Effects of dihydrotestosterone benzoate administration on gonadotropin secretion in ovariectomized pony mares. Garza F Jr, et al. **J Anim Sci** 1985 Jul;61(1):240–4

Catechol oestradiol control of FSH-stimulated granulosa cell steroidogenesis. Hudson KE, et al. **J Endocrinol** 1985 Jul; 106(1):R1–4

Effects of LH-releasing hormone antagonist or lesions of the medial basal hypothalamus on periovulatory gonadotrophin release in female rats. Rush ME. **J Endocrinol** 1985 Sep;106(3):361–6

Time series analysis of plasma LH and FSH concentrations as a method of assessing episodic secretion. McLeod BJ, et al. **J Reprod Fertil** 1985 Jul;74(2):575–87

Plasma LH and FSH responses and ovarian activity in prepubertal heifers treated with repeated injections of low doses of GnRH for 72 h. McLeod BJ, et al. **J Reprod Fertil** 1985 Jul;74(2):589–96

Twin pregnancy after pituitary desensitisation with LHRH agonist and pure FSH [letter] Shaw RW, et al. **Lancet** 1985 Aug 31; 2(8453):506–7

Effects of the 1,5-benzodiazepine clobazam on pituitary hormones in the male rat. Valli M, et al. **Methods Find Exp Clin Pharmacol** 1985 Apr; 7(4):179–81

Electrofocusing fractionation of follicle stimulating hormone in pituitary cell culture extracts from male and female rats. Foulds LM, et al. **Mol Cell Endocrinol** 1985 Jul;41(2–3):129–36

A prolactin-inhibiting factor within the precursor for human gonadotropin-releasing hormone. Nikolics K, et al. **Nature** 1985 Aug 8–14;316(6028):511–7

[Gonadotropin stimulation during LH/RH analog-induced inhibition of pituitary function] Bettendorf G, et al. **Geburtshilfe Frauenheilkd** 1985 Jul;45(7):431–7 (Eng. Abstr.) **(Ger)**

GABA

Memory effects of GABA-ergic antagonists in rats trained with two-way active avoidance tasks. Yonkov DI, et al. **Acta Physiol Pharmacol Bulg** 1985;11(2):44–9

gamma-Aminobutyric acid concentrations are maintained in anoxic turtle brain. Lutz PL, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):R372–4

Uptake and release of gamma-aminobutyric acid in guinea pig gallbladder. Saito N, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):G192–6

Modulation of a GABA-ergic inhibitory circuit in the in vitro hippocampus by etomidate isomers. Ashton D, et al. **Anesth Analg** 1985 Oct;64(10):975–80

An inhibitory protein of intestinal fluid secretion reverses neuronal GABA transport. Lange S, et al. **Biochem Biophys Res Commun** 1985 Aug 15; 130(3):1032–6

A gamma-aminobutyric acid-specific transport mechanism in mammalian kidney. Goodyer PR, et al. **Biochim Biophys Acta** 1985 Aug 8; 818(1):45–54

An unusual effect of gamma-aminobutyric acid on synaptic transmission of frog tectal neurones in vitro. Nistri A, et al. **Br J Pharmacol** 1985 Aug;85(4):917–21

Circannual variations of GABA content in cytosolic and crude synaptosomal fractions in some brain areas of the European hamster. Ciesielski L, et al. **Brain Res** 1985 Sep 30;344(1):146–9

A calculation method for evaluating the time course of GABA removal from a synaptic cleft by presynaptic uptake systems. Cupello A, et al. **Brain Res** 1985 Sep 2;342(1):176–8

Coexistence of immunoreactivities for glutamate decarboxylase and tyrosine hydroxylase in some neurons in the periglomerular region of the rat main olfactory bulb: possible coexistence of gamma-aminobutyric acid (GABA) and dopamine. Kosaka T, et al. **Brain Res** 1985 Sep 16; 343(1):166–71

Growth cones isolated from developing rat forebrain: uptake and release of GABA and noradrenaline. Lockerbie RO, et al. **Brain Res** 1985 Aug; 353(2):265–75

Evidence for impaired GABAergic activity in the substantia nigra of amygdaloid kindled rats. Löscher W, et al. **Brain Res** 1985 Jul 22; 339(1):146–50

Evidence for GABA mediation of sympathetic inhibition evoked from midline medullary depressor sites. McCall RB, et al. **Brain Res** 1985 Jul 29;339(2):356–60

Development of sensitivity to GABA and glycine in cultured cerebellar neurons. Mori-Okamoto J, et al. **Brain Res** 1985 Jun;352(2):249–58

Effects on the caudate spindle in rats of taurine and gamma-aminobutyric acid (GABA) microinjected into the substantia nigra: involvement of the dopaminergic system. Okuyama S, et al. **Brain Res** 1985 Sep 9; 342(2):366–8

Newly identified GABAergic neurons in regions of the ventrolateral medulla which regulate blood pressure. Ruggiero DA, et al. **Brain Res** 1985 Jul 22;339(1):171–7

Effects of 4-aminopyridine, GABA and bicuculline on cutaneous receptive fields of cat dorsal horn neurons. Saadé N, et al. **Brain Res** 1985 Oct 7;344(2):356–9

GABA mimetics decrease extracellular concentrations of 5-HIAA (as measured by in vivo voltammetry) in the dorsal raphe of the rat. Scatton B, et al. **Brain Res** 1985 Aug 26;341(2):372–6

Some factors that influence the decrement in the response to GABA during its continuous iontophoretic application to hippocampal neurons. Thalmann RH, et al. **Brain Res** 1985 Sep 9;342(2):219–33

Localization of GABA immunoreactivity in the auditory brainstem of guinea pigs. Thompson GC, et al. **Brain Res** 1985 Jul 22; 339(1):119–22

GABA activates different types of chloride-conducting receptor-ionophore complexes in a dose-dependent manner. Yasui S, et al. **Brain Res** 1985 Sep 30;344(1):176–80

Stimulated release of endogenous GABA and glycine from the goldfish retina. Yazulla S, et al. **Brain Res** 1985 Oct 21;345(2):384–8

Involvement of growth hormone-releasing factor in growth hormone secretion induced by gamma-aminobutyric acid in conscious rats. Murakami Y, et al. **Endocrinology** 1985 Aug;117(2):787–9

Evidence for a GABAergic control of the exercise-induced rise in GH in man. Steardo L, et al. **Eur J Clin Pharmacol** 1985;28(5):607–9

GABAergic drugs and sexual behaviour in the male rat. Agmo A, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):371–8

Effect of local GABA administration on rat ovarian blood flow, and on progesterone and estradiol secretion. Erdö S, et al. **Eur J Pharmacol** 1985 May 20;111(3):397–400

Inhibition by yohimbine of the calcium-dependent evoked release of [3H]GABA in rat and mouse brain slices in vitro. Maurin Y, et al. **Eur J Pharmacol** 1985 Apr 23;111(1):37–48

Progabide reverses the nigral substance P reduction induced by chronic impairment of dopaminergic transmission. Zivkovic B, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):253–5

The non-GABAergic nature of 3H-baclofen binding in rat peripheral tissues. Kato K, et al. **Gen Pharmacol** 1985;16(4):327–33

Insulin and glucagon secretion by the dog pancreas during intravenous and oral administration of gamma aminobutyric acid (GABA). Minuk GY, et al. **Horm Metab Res** 1985 Jun;17(6):313–4

Lateral differences in the GABAergic system of the rat striatum. Guarneri P, et al. **Ital J Neurol Sci** 1985 Jun;6(2):173–6

Reconstitution and purification of the sodium- and chloride-coupled gamma-aminobutyric acid transporter from rat brain. Radian R, et al. **J Biol Chem** 1985 Sep 25;260(21):11859–65

GABAergic neurons containing CCK-8-like and/or VIP-like immunoreactivities in the rat hippocampus and dentate gyrus. Kosaka T, et al. **J Comp Neurol** 1985 Sep 22;239(4):420–30

Prolactin in cerebrospinal fluid increases the synthesis and release of hypothalamic gamma-aminobutyric acid. Locatelli V, et al. **J Endocrinol** 1985 Sep;106(3):323–8

In vivo effects of anticonvulsant drugs on nerve terminal (synaptosomal) GABA levels in 11 brain regions of the rat. Löscher W, et al. **J Neural Transm** 1985;63(2):157–67

1-Piperideine as an in vivo precursor of the gamma-aminobutyric acid homologue 5-aminopentanoic acid. Callery PS, et al. **J Neurochem** 1985 Sep;45(3):946–8

gamma-Aminobutyric acid metabolism and behavioral effects after intraventricular injection of spermine in chicks. Di Giorgio RM, et al. **J Neurochem** 1985 Sep;45(3):739–43

Improved method for isolating synaptosomes from 11 regions of one rat brain: electron microscopic and biochemical characterization and use in the study of drug effects on nerve terminal gamma-aminobutyric acid in vivo. Löscher W, et al. **J Neurochem** 1985 Sep;45(3):879–89

Uptake and release of gamma-aminobutyric acid in the guinea pig cochlear nucleus after axotomy of cochlear and centrifugal fibers. Potashner SJ, et al. **J Neurochem** 1985 Nov;45(5):1558–66

Binding of lanthanum ions and ruthenium red to synaptosomes and its effects on neurotransmitter release. Tapia R, et al. **J Neurochem** 1985 Nov;45(5):1464–70

Succinic semialdehyde as a substrate for the formation of gamma-aminobutyric acid. van Bemmelen FJ, et al. **J Neurochem** 1985 Nov;45(5):1471–4

Conversion of gamma-hydroxybutyrate to gamma-aminobutyrate in vitro. Vayer P, et al. **J Neurochem** 1985 Sep;45(3):810–4

Methionine-induced changes in glutamate, aspartate, glutamine, and gamma-aminobutyrate levels in brain tissue. Wood JD, et al. **J Neurochem** 1985 Sep;45(3):777–83

Properties of succinic semialdehyde dehydrogenase in cultured human lymphoblasts. Gibson KM, et al. **J Neurogenet** 1985 Apr;2(2):111–22

Rectification of single GABA-gated chloride channels in adult hippocampal neurons. Gray R, et al. **J Neurophysiol** 1985 Jul; 54(1):134–42

Characterization of GABAergic neurons in cerebellar primary cultures and selective neurotoxic effects of a serum fraction. Aloisi F, et al. **J Neurosci** 1985 Aug;5(8):2001–8

Modulation of neurotransmitter action: control of the gamma-aminobutyric acid response through the benzodiazepine receptor. Chan CY, et al. **J Neurosci** 1985 Sep;5(9):2365–73

The morphology of physiologically identified GABAergic neurons in the somatic sensory part of the thalamic reticular nucleus in the cat. Yen CT, et al. **J Neurosci** 1985 Aug;5(8):2254–68

GABA inhibits excitatory neurotransmission in rat pelvic ganglia. Maggi CA, et al. **J Pharm Pharmacol** 1985 May;37(5):349–51

Upregulation of gamma-aminobutyric acid (GABA) B binding sites in rat frontal cortex: a common action of repeated administration of different classes of antidepressants and electroshock. Lloyd KG, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):191–9

An intracellular analysis of gamma-aminobutyric-acid-associated ion movements in rat sympathetic neurones. Ballanyi K, et al. **J Physiol (Lond)** 1985 Aug;365:41–58

Action and localization of gamma-aminobutyric acid in the cat retina. Bolz J, et al. **J Physiol (Lond)** 1985 May;362:369–93

Effect of excitatory amino acids on gamma-aminobutyric acid release from frog horizontal cells. Cunningham JR, et al. **J Physiol (Lond)** 1985 May;362:51–67

Substance P provoked gamma-aminobutyric acid release from the myenteric plexus of the guinea-pig small intestine. Tanaka C, et al. **J Physiol (Lond)** 1985 May;362:319–29

Elevated levels of gamma amino butyric acid (GABA) in the thymus gland during the immune response. Hall NR, et al. **Lymphokine Res** 1985 Fall;4(4):339–41

Uptake of GABA by bovine adrenal medulla slices. Oset Gasque MJ, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):372–5

Lack of effect of GABA on [3H]leucine incorporation into a rat oviduct ribosomal system. Orensanz LM, et al. **Neurochem Res** 1985 Jun; 10(6):789–96

Effects of bath-applied GABA on the firing pattern of cells in an in vitro preparation of mammalian cerebral cortex. Bagust J, et al. **Neuropharmacology** 1985 Jun;24(6):551–4

Effect of aminooxyacetic acid on gamma-aminobutyric acid release from frog retina. Bedwani JR, et al. **Neuropharmacology** 1985 Jun; 24(6):495–7

Effects of a depressant/convulsant pair of glutarimides on neuronal activity in the isolated spinal cord of the immature rat. Nicholson GM, et al. **Neuropharmacology** 1985 Jun;24(6):461–4

Stability of the amino acid content of nerve endings after administration of gamma-aminobutyrate agonists and antagonists. Wood JD, et al. **Neuropharmacology** 1985 Jul;24(7):685–7

Spontaneous inhibitory postsynaptic potentials in guinea pig neocortex and olfactory cortex neurones. Galvan M, et al. **Neurosci Lett** 1985 Jun 12;57(2):131–5

The gamma-aminobutyric acid-mimetic action of omega-aminocaprylic

acid in rat cortex. Hicks TP, et al. **Neurosci Lett** 1985 Jun 24; 57(3):295–9

On the binding of gamma-[3H]aminobutyric acid to the rat oviduct [letter] Orensanz LM, et al. **Neurosci Lett** 1985 Jun 24;57(3):213–4

Sodium-dependent, calmodulin-dependent transmitter release from synaptosomes. Sandoval ME, et al. **Neurosci Lett** 1985 May 23; 56(3):271–7

Opposite effects of monosodium glutamate on the dopaminergic and GABAergic innervations of the median eminence and the intermediate lobe in the mouse. Stoeckel ME, et al. **Neurosci Lett** 1985 May 23; 56(3):249–55

GABAergic intrinsic interneurons in the red nucleus of the cat demonstrated with combined immunocytochemistry and anterograde degeneration methods. Katsumaru H, et al. **Neurosci Res** 1984 Feb; 1(1):35–44

Patch-clamp studies of chloride channels activated by gamma-aminobutyric acid in cultured hippocampal neurones of the rat. Ozawa S, et al. **Neurosci Res** 1984 Oct;1(5):275–93

Angiotensin II-induced depression of Purkinje cell firing and possible modulatory action on GABA responses. Tongroach P, et al. **Neurosci Res** 1984 Oct;1(5):369–72

Reduction of inhibition by a benzodiazepine antagonist, Ro15-1788, in the rat hippocampal slice. King GL, et al. **Neuroscience** 1985 Jun; 15(2):371–8

The role of the gamma-aminobutyrate system in the interactions of cortical evoked potentials. Toldi J, et al. **Neuroscience** 1985 Aug; 15(4):977–81

Effect of valproate on brain GABA: comparison with various medium chain fatty acids. Keane PE, et al. **Pharmacol Res Commun** 1985 Jun; 17(6):547–55

Ion channels activated by L-glutamate and GABA in cultured cerebellar neurons of the rat. Cull-Candy SG, et al. **Proc R Soc Lond [Biol]** 1985 May 22;224(1236):367–73

The GABA hypothesis of depression and antidepressant drug action. Bartholini G, et al. **Psychopharmacol Bull** 1985;21(3):385–8

GABAergic effects of reserpine following chronic treatment. Suzdak PD, et al. **Psychopharmacology (Berlin)** 1985;87(2):157–60

Actions and interactions of GABA and benzodiazepines in the mouse hippocampal slice. Biscoe TJ, et al. **Q J Exp Physiol** 1985 Jul; 70(3):313–28

The anion selectivity of GABA-mediated post-synaptic potentials in mouse hippocampal cells. Biscoe TJ, et al. **Q J Exp Physiol** 1985 Jul; 70(3):305–12

Inhibition of gamma-[3H]aminobutyric acid uptake by organotin compounds in vitro. Costa LG. **Toxicol Appl Pharmacol** 1985 Jul; 79(3):471–9

Probicyclophosphates: monocyclophosphates as potential prodrugs for bicyclophosphate GABA antagonists. Toia RF, et al. **Toxicol Appl Pharmacol** 1985 Oct;81(1):50–7

Inhibition of 4-aminobutyric acid (GABA) turnover by chlordane. Fishman BE, et al. **Toxicol Lett** 1985 Aug;26(2-3):219–23

GABAergic inhibition and orientation selectivity of neurons in the kitten visual cortex at the time of eye opening. Tsumoto T, et al. **Vision Res** 1985;25(3):383–8

[Effect of 2 new GABA-ergic agents on apomorphine stereotypy in the rat] Vamvakidès A. **Agressologie** 1985 Jan;26(1):63–5 (Eng. Abstr.) **(Fre)**

[3 new GABA-ergics: research on their possible site of action] Vamvakidès A. **Agressologie** 1985 Jun;26(7):591–4 (Eng. Abstr.) **(Fre)**

[GABAergic control of hypophyseal gonadotropic function and prolactin. Demonstration by valproic acid] Giroud M, et al. **J Gynecol Obstet Biol Reprod (Paris)** 1985;14(2):163–9 (Eng. Abstr.) **(Fre)**

[Effects of calcium hopantenate on GABA receptors in the aged rat brain cortex] Ogawa N, et al. **Nippon Ronen Igakkai Zasshi** 1985 May; 22(3):264–5 **(Jpn)**

[GABAergic neurons in the mammalian intestine] Taniyama K. **Nippon Yakurigaku Zasshi** 1985 May;85(5):305–13 (313 ref.) (Eng. Abstr.) **(Jpn)**

[Effect of manganese chloride poisoning during pregnancy and lactation on the levels and synthesis of gamma-aminobutyric acid (GABA) in the rat brain] Kosicka B, et al. **Neuropatol Pol** 1985;23(2):201–9 (Eng. Abstr.) **(Pol)**

[Effect of fenibut on the GABA B receptors of the spinal motor neurons] Abramets II, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):698–700 (Eng. Abstr.) **(Rus)**

[Nature of a mediator participating in reflex inhibition of the activity of the lymphatic center of the frog] Serbeniuk TsV, et al. **Fiziol Zh SSSR** 1985 Jul;71(7):889–95 (Eng. Abstr.) **(Rus)**

[Early changes in GABA and glutamate levels and aminotransferase activity in parts of the rat brain following whole-body gamma irradiation at an absolutely lethal dose] Rozanov VA, et al. **Radiobiologiia** 1985 May–Jun;25(3):384–8 (Eng. Abstr.) **(Rus)**

[Effect of a derivative of GABA, phenibut, on behavior and the activity of visual cortex neurons of the rabbit during elaboration of a defensive reflex and internal inhibition] Shul'gina GI, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):695–702 (Eng. Abstr.)**(Rus)**

GALVANIC SKIN RESPONSE

Two types of changes in skin conductance activity after intraventricular administration of 6-hydroxydopamine in rats. Yamamoto K, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(3):245–50

GENERALIZATION, STIMULUS

Midazolam cue in rats: generalization tests with anxiolytic and other drugs. Garcha HS, et al. **Psychopharmacology (Berlin)** 1985;87(2):233–7

GENETICS, BEHAVIORAL

The genetic architecture of hyponeophagia and the action of diazepam in rats. Shephard RA, et al. **Behav Genet** 1985 May;15(3):265–86

GLUCURONIDASE

Circadian and seasonal rhythm of beta-glucuronidase in rat liver. Bhattacharya RD. **Cell Mol Biol** 1985;31(4):305–7

Diurnal variations in the transferases and hydrolases involved in glucuronide and sulfate conjugation of rat liver. Bélanger PM, et al. **Drug Metab Dispos** 1985 May–Jun;13(3):386–9

Fibroblasts acquire beta-glucuronidase by direct and indirect transfer during co-culture with macrophages. McNamara A, et al. **Exp Cell Res** 1985 Sep;160(1):150–7

Genetic variation for enzyme structure and systemic regulation in two new haplotypes of the beta-glucuronidase gene of Mus musculus castaneus. Pfister K, et al. **J Biol Chem** 1985 Sep 25; 260(21):11588–94

Weak androgen reduces the rate constant of beta-glucuronidase induction. Bullock LP, et al. **Mol Cell Endocrinol** 1985 Jul;41(2-3):179–85

GONADOTROPINS, PITUITARY

Desensitization of testicular ornithine decarboxylase to gonadotropin releasing hormone and gonadotropic hormones. Madhubala R, et al. **Biochem Int** 1985 Aug;11(2):225–32

The corpus luteum of the primate menstrual cycle is capable of recovering from a transient withdrawal of pituitary gonadotropin support. Hutchison JS, et al. **Endocrinology** 1985 Sep;117(3):1043–9

Role of GnRH in the maturation of pituitary gonadotroph function. Clayton RN. **J Reprod Fertil** 1985 Sep;75(1):307–15 (62 ref.)

The effects of thymus-derived peptides on hypothalamic LRF and pituitary gonadotropin content in prepubertal congenitally athymic nude mice and their normal heterozygous littermates. Strich G, et al. **J Reprod Immunol** 1985 Jun;7(4):351–9

[Pulsed administration of gonadoliberine (GnRH) in the treatment of anovulation] Jaffiol C, et al. **Bull Acad Natl Med (Paris)** 1985 Jan; 169(1):95–8 (Eng. Abstr.) **(Fre)**

[GABAergic control of hypophyseal gonadotropic function and prolactin. Demonstration by valproic acid] Giroud M, et al. **J Gynecol Obstet Biol Reprod (Paris)** 1985;14(2):163–9 (Eng. Abstr.) **(Fre)**

GUANETHIDINE

Protection from guanethidine-induced neuronal destruction by nerve growth factor: effect of NGF on immune function. Manning PT, et al. **Brain Res** 1985 Aug 5;340(1):61–9

Reproductive physiology and behavior in the male rat following acute and chronic peripheral adrenergic depletion by guanethidine. Stefanick ML, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):55–63

HALOPERIDOL

Lipid peroxidation as a possible mechanism for the neurotoxic and nephrotoxic effects of a combination of lithium carbonate and haloperidol. Sawas AH, et al. **Arch Int Pharmacodyn Ther** 1985 Aug; 276(2):301–12

Interconversions of haloperidol and reduced haloperidol in guinea pig and rat liver microsomes. Korpi ER, et al. **Biochem Pharmacol** 1985 Aug 15;34(16):2923–7

Plasma cortisol levels in mania: associated clinical ratings and changes during treatment with haloperidol. Cookson JC, et al. **Br J Psychiatry** 1985 May;146:498–502

Treatment of rapid cycling affective illness [letter] Lowe MR. **Br J Psychiatry** 1985 May;146:558

In vivo voltammetric and behavioural evidence for somatodendritic autoreceptor control of mesolimbic dopamine neurones. Maidment NT, et al. **Brain Res** 1985 Jul 15;338(2):317–25

Effect of transition or heavy metals on [3H]haloperidol binding in rat striatal membranes in vitro. Komulainen H, et al. **Eur J Pharmacol** 1985 Aug 15;114(2):113–9

Chronic haloperidol causes increase in salivary response and alpha 1-adrenoceptors in submandibular gland of the rat. Pazo JH, et al.

Eur J Pharmacol 1985 Jul 11;113(1):121–4

Repetitive measurement of monoamine metabolite levels in cerebrospinal fluid of conscious rats: effects of reserpine and haloperidol. Scheinin H, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):345–51

Comparison of injectable molindone and haloperidol followed by oral dosage forms in acutely ill schizophrenics. Escobar JI, et al. **J Clin Psychiatry** 1985 Aug;46(8 Pt 2):15–9

Quantification of reduced haloperidol and haloperidol by radioimmunoassay. Browning JL, et al. **J Immunoassay** 1985; 6(1–2):45–66

Synthesis of high specific activity [75Br]- and [77Br]bromperidol and tissue distribution studies in the rat. Moerlein SM, et al. **J Med Chem** 1985 Sep;28(9):1319–24

Quantification of dopaminergic supersensitization using apomorphine–induced behavior in the mouse. Randall PK. **Life Sci** 1985 Oct 14;37(15):1419–23

Use of mRNA hybridization and radioimmunoassay to study mechanisms of drug–induced accumulation of enkephalins in rat brain structures. Mocchetti I, et al. **Mol Pharmacol** 1985 Jul;28(1):86–91

Long–term haloperidol treatment elevates beta–endorphin levels in the intermediate pituitary but not in rat brain. Millington WR, et al. **Neuropeptides** 1985 Jul;6(4):365–72

Electrophysiological interactions between haloperidol and reduced haloperidol, and dopamine, norepinephrine and phencyclidine in rat brain. Kirch DG, et al. **Neuropharmacology** 1985 May;24(5):375–9

Comparative efficacy of red cell and plasma haloperidol as predictors of clinical response in schizophrenia. Smith RC, et al. **Psychopharmacology (Berlin)** 1985;85(4):449–55

Neuroleptic–induced priapism. Gomez EA. **Tex Med** 1985 Sep; 81(9):47–8

[Schizophrenically disordered time perception and its modification by neuroleptics] Heim M, et al. **Psychiatr Neurol Med Psychol (Leipz)** 1985 Jul;37(7):410–5 (Eng. Abstr.) **(Ger)**

[Evaluation of the efficacy of haloperidol decanoate in the treatment of chronic psychotic hospital patients] Marchant N, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):37–41 (Eng. Abstr.) **(Spa)**

[Malignant hyperthermia caused by neuroleptics] Escolano Villén F, et al. **Rev Esp Anestesiol Reanim** 1985 Jul–Aug;32(4):189–91 (Eng. Abstr.) **(Spa)**

HEXOBARBITAL

Route– and dose–dependent pharmacokinetics of hexobarbitone in the rat: a re–evaluation of the use of sleeping times in metabolic studies. Van der Graaff M, et al. **J Pharm Pharmacol** 1985 Aug;37(8):550–4

The inhibition of bacterial bioluminescence by xenobiotics. Danilov VS, et al. **Xenobiotica** 1985 Apr;15(4):271–6

HISTAMINE

Effects of histamine and cimetidine on the levels of serotonin and 5–hydroxyindoleacetic acid in various parts of the digestive tract and in the blood and brain of rats. Kleinrok Z, et al. **Acta Physiol Pol** 1984 Mar–Apr;35(2):125–30

Effects of histamine and H1 and H2–receptor antagonists on the wet–dog–shaking episodes in rats induced with lithium chloride. Rajtar G, et al. **Acta Physiol Pol** 1984 Mar–Apr;35(2):131–5

Effect of gastrin, histamine, serotonin, and adrenergic amines on gastroesophageal sphincter pressure in the dog. Strombeck DR, et al. **Am J Vet Res** 1985 Aug;46(8):1684–90

Histamine is an antagonist of the acetylcholine receptor at the frog endplate. Ariyoshi M, et al. **Br J Pharmacol** 1985 May;85(1):65–73

Histamine–immunoreactive endocrine cells in the adrenal medulla of the rat. Häppölä O, et al. **Brain Res** 1985 Jul 29;339(2):393–6

Decrease in histamine turnover in the brain of spontaneously hypertensive rats. Oishi R, et al. **Brain Res** 1985 Sep 16;343(1):180–3

Histamine–mediated acetylcholine release in the guinea–pig ileum. Rubinstein R, et al. **Eur J Pharmacol** 1985 May 8;111(2):245–50

Effect of histamine on basal and TRH/LH–RH–stimulated PRL and LH secretion during different phases of the menstrual cycle in normal women. Knigge U, et al. **Neuroendocrinology** 1985 Oct;41(4):337–41

Positive interaction between leukotriene C4 and histamine and other mediators on vascular tissues. Omini C, et al. **Prostaglandins** 1985 Jun; 29(6):1009–20

Antramine (antral histamine) antagonizes somatostatin inhibition on endogenous gastrin–induced gastric secretion. A new hypothesis for the role of histamine in gastric secretion regulation. Vatier J, et al. **Scand J Gastroenterol** 1985 Aug;20(6):671–6

[Effect of antidepressive drugs and histamine H1 receptor blockaders on histamine level in rat brain] Zawilska J, et al. **Folia Med Cracov** 1984; 25(3–4):297–306 (Eng. Abstr.) **(Pol)**

HOMOVANILLIC ACID

Oral dosing of rats with polychlorinated biphenyls increases urinary homovanillic acid production. Seegal RF, et al. **J Toxicol Environ Health** 1985;15(5):575–86

Correlations between aminergic metabolites simultaneously obtained from human CSF and brain. Stanley M, et al. **Life Sci** 1985 Oct 7; 37(14):1279–86

HYDANTOINS

Interaction of prostaglandin D2 with prostacyclin, carbacyclin and the hydantoin prostaglandin, BW245C, in guinea–pig platelets. Hamid S, et al. **Br J Pharmacol** 1985 May;85(1):285–90

Stereoselective mephobarbital hydroxylation cosegregates with mephenytoin hydroxylation. Küpfer A, et al. **Clin Pharmacol Ther** 1985 Oct;38(4):414–8

Interethnic differences in genetic polymorphism of debrisoquin and mephenytoin hydroxylation between Japanese and Caucasian populations. Nakamura K, et al. **Clin Pharmacol Ther** 1985 Oct; 38(4):402–8

Reversed–phase high–performance liquid chromatographic separation and quantitation of phenylthiohydantoin derivatives of 25 amino acids, including those of cysteic acid, 4–hydroxyproline, methionine sulfone, S–carboxymethylcysteine and S–methylcysteine. Kolbe HV, et al. **J Chromatogr** 1985 Jun 26;327:1–7

Phenotypic differences in mephenytoin pharmacokinetics in normal subjects. Wedlund PJ, et al. **J Pharmacol Exp Ther** 1985 Sep; 234(3):662–9

Participation of a rat liver cytochrome P–450 induced by pregnenolone 16 alpha–carbonitrile and other compounds in the 4–hydroxylation of mephenytoin. Shimada T, et al. **Mol Pharmacol** 1985 Aug; 28(2):215–9

HYDRAZINES

Determination of isoniazid, acetylisoniazid, acetylhydrazine and diacetylhydrazine in biological fluids by high–performance liquid chromatography. von Sassen W, et al. **J Chromatogr** 1985 Feb 27; 338(1):113–22

Pharmacological actions of SQ 29,548, a novel selective thromboxane antagonist. Ogletree ML, et al. **J Pharmacol Exp Ther** 1985 Aug; 234(2):435–41

[Cyclic hydrazides of mucobromic acid. (II)] Dorneanu M, et al. **Rev Med Chir Soc Med Nat Iasi** 1984 Oct–Dec;88(4):712–4 (Eng. Abstr.) **(Rum)**

[Behavior disorder in rats induced by Madopar and its pharmacological correction] Bondarenko NA, et al. **Farmakol Toksikol** 1985 Jul–Aug; 48(4):31–4 (Eng. Abstr.) **(Rus)**

HYDRAZONES

Synthesis and hypoglycemic activity of N–alkylated hydrazonopropionic acids. Wolff HP, et al. **J Med Chem** 1985 Oct;28(10):1436–40

HYDROXYBUTYRATES

The phosphonomethyl analogue of 3–phosphoglycerate is a potent competitive inhibitor of phosphoglycerate mutases. McAleese SM, et al. **Biochem J** 1985 Sep 1;230(2):535–42

Endogenous sugar acid control of hypothalamic neuron activity and gastric acid secretion in rats. Shiraishi T, et al. **Brain Res Bull** 1985 May;14(5):431–8

Effects of insulin on net hepatic metabolism of acetate and beta–hydroxybutyrate in sheep (Ovis aries). Brockman RP, et al. **Comp Biochem Physiol** [A] 1985;81(2):255–7

Stimulation by 3–hydroxybutyrate of pyruvate carboxylation in mitochondria from rat liver. Siess EA. **Eur J Biochem** 1985 Oct 1; 152(1):131–6

Evidence for a role of high Km aldehyde reductase in the degradation of endogenous gamma–hydroxybutyrate from rat brain. Vayer P, et al. **FEBS Lett** 1985 Oct 7;190(1):55–60

Conversion of gamma–hydroxybutyrate to gamma–aminobutyrate in vitro. Vayer P, et al. **J Neurochem** 1985 Sep;45(3):810–4

Properties of succinic semialdehyde dehydrogenase in cultured human lymphoblasts. Gibson KM, et al. **J Neurogenet** 1985 Apr;2(2):111–22

[Use of Gamma–OH by the oral route in children] Lansade A, et al. **Agressologie** 1985 Mar;26(3):277–8 (Eng. Abstr.) **(Fre)**

[State of the peripheral catecholaminergic systems during pharmacologic correction of immobilization stress using sodium oxybutyrate] Khalsman EB, et al. **Biull Eksp Biol Med** 1985 Sep;100(9):317–9 (Eng. Abstr.) **(Rus)**

[Combined action of lithium salts and serotonin on the caudate nucleus] Zamoshchina TA, et al. **Biull Eksp Biol Med** 1985 Aug; 100(8):191–3 (Eng. Abstr.) **(Rus)**

HYDROXYDOPAMINES

Facilitation of spontaneous and learned spatial behaviours following 6–hydroxydopamine lesions of the lateral septum: a cholinergic hypothesis. Galey D, et al. **Brain Res** 1985 Aug 5;340(1):171–4

The effect of water–deprivation on locomotor activity in rats treated with

6-hydroxydopamine. Seiden LS, et al. **Brain Res** 1985 Jul 1; 337(2):225-32

Behavioral study after local injection of 6-hydroxydopamine into the nucleus accumbens in the rat. Taghzouti K, et al. **Brain Res** 1985 Sep 30;344(1):9-20

Localisation of neuropeptide Y in nerves of the rat cardiovascular system and the effect of 6-hydroxydopamine. Allen JM, et al. **Cardiovasc Res** 1985 Sep;19(9):570-7

Decrease in adrenaline content of various organs of the rat after 6-hydroxydopamine. Sudo A. **Eur J Pharmacol** 1985 Aug 7; 114(1):79-83

Substantial reduction of noradrenaline in kitten visual cortex by intraventricular injections of 6-hydroxydopamine does not always prevent ocular dominance shifts after monocular deprivation. Daw NW, et al. **Exp Brain Res** 1985;59(1):30-5

Effect of 6-hydroxydopamine on the metabolism of endogenous octopamines and catecholamines. Ibrahim KE, et al. **J Pharm Pharmacol** 1985 Jul;37(7):496-7

Dopamine agonist-induced locomotor activity in rats treated with 6-hydroxydopamine at differing ages: functional supersensitivity of D-1 dopamine receptors in neonatally lesioned rats. Breese GR, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):447-55

Hyperactivity induced by stimulation of separate dopamine D-1 and D-2 receptors in rats with bilateral 6-OHDA lesions. Arnt J. **Life Sci** 1985 Aug 26;37(8):717-23

Inactivation by 6-hydroxydopamine of the cerebral factor(s) responsible for the inhibition of the autoxidation of norepinephrine in vitro. Kovachich GB. **Neurosci Lett** 1985 Jul 31;58(2):245-50

6-Hydroxydopamine induces degenerative changes in innervation of the rat pituitary gland. Saland LC, et al. **Neurosci Lett** 1985 Jun 4; 57(1):49-55

Neonatal 6-hydroxydopamine potentiates clonidine's locomotor effects throughout maturation in the rat. Smythe JW, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):1075-8

Two types of changes in skin conductance activity after intraventricular administration of 6-hydroxydopamine in rats. Yamamoto K, et al. **Prog Neuropsychopharmacol Biol Psychiatry** 1985;9(3):245-50

HYDROXYINDOLEACETIC ACID

Effects of histamine and cimetidine on the levels of serotonin and 5-hydroxyindoleacetic acid in various parts of the digestive tract and in the blood and brain of rats. Kleinrok Z, et al. **Acta Physiol Pol** 1984 Mar-Apr;35(2):125-30

Serotonin content of foods: effect on urinary excretion of 5-hydroxyindoleacetic acid. Feldman JM, et al. **Am J Clin Nutr** 1985 Oct;42(4):639-43

Higher CSF levels of HVA and 5-HIAA in delusional compared to nondelusional depression [letter] Aberg-Wistedt A, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):925-6

Effects of benzene and pyridine on the concentration of mouse striatal tryptamine and 5-hydroxytryptamine. Juorio AV, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3774-6

GABA mimetics decrease extracellular concentrations of 5-HIAA (as measured by in vivo voltammetry) in the dorsal raphe of the rat. Scatton B, et al. **Brain Res** 1985 Aug 26;341(2):372-6

Measurement of 5-HIAA levels in ventricular CSF (by LCEC) and in striatum (by in vivo voltammetry) during pharmacological modifications of serotonin metabolism in the rat. Mignot E, et al. **J Neural Transm** 1985;62(1-2):117-24

Correlations between aminergic metabolites simultaneously obtained from human CSF and brain. Stanley M, et al. **Life Sci** 1985 Oct 7; 37(14):1279-86

Increase in levels and ex vivo release of thyrotrophin-releasing hormone (TRH) in specific regions of the CNS of the rat by chronic treatment with antidepressants. Lighton C, et al. **Neuropharmacology** 1985 May; 24(5):401-6

Low HVA and normal 5HIAA CSF levels in drug-free schizophrenic patients compared to healthy volunteers: correlations to symptomatology and family history. Lindström LH. **Psychiatry Res** 1985 Apr;14(4):265-73

CSF monoamine metabolites in chronic schizophrenic patients who attempt suicide. Roy A, et al. **Psychol Med** 1985 May;15(2):335-40

HYDROXYTRYPTOPHAN

Sexual differences in the effect of serotonin on LH secretion in rats. Moguilevsky JA, et al. **Acta Endocrinol (Copenh)** 1985 Jul; 109(3):320-5

Effect of passive immunization with antisera to vasoactive intestinal polypeptide and peptide histidine isoleucine amide on 5-hydroxy-L-tryptophan-induced prolactin release in rats. Kaji H, et al. **Endocrinology** 1985 Nov;117(5):1914-9

Maternal aggression in mice: effects of treatments with PCPA, 5-HTP and 5-HT receptor antagonists. Ieni JR, et al. **Eur J Pharmacol** 1985 May 8;111(2):211-20

Specific antagonism of enteric neural serotonin receptors by dipeptides of 5-hydroxytryptophan: evidence that serotonin is a mediator of slow synaptic excitation in the myenteric plexus. Takaki M, et al. **J Neurosci** 1985 Jul;5(7):1769-80

The influence of pharmacological manipulation of serotonin on serum growth hormone and luteinizing hormone levels in young turkeys (Meleagris gallopavo). Fehrer SC, et al. **Poult Sci** 1985 Jul; 64(7):1356-62

Circadian variation in behavioural responses to central 5-HT receptor stimulation in the mouse. Moser PC, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):223-7

[Correlation between the number of serotonin type 2 receptors in the frontal cortex of the mouse brain and the expressivity of serotonin-dependent head twitches] Popova NK, et al. **Biull Eksp Biol Med** 1985 Sep;100(9):322-4 (Eng. Abstr.) **(Rus)**

HYPOCHONDRIASIS

Dysmorphophobia and monosymptomatic hypochondriasis [letter] Thomas CS. **Am J Psychiatry** 1985 Sep;142(9):1121

IMIPRAMINE

Maintenance treatment of recurrent unipolar depression: pharmacology and psychotherapy. Frank E, et al. **Adv Biochem Psychopharmacol** 1985; 40:139-51

Research overview of drug therapy in recurrent and chronic depression. Prien RF. **Adv Biochem Psychopharmacol** 1985;40:121-30

Imipramine in the treatment of agoraphobia: dose-response relationships. Mavissakalian M, et al. **Am J Psychiatry** 1985 Sep;142(9):1032-6

A lithium-tricyclic combination for treatment of depression [letter] Pande AD, et al. **Am J Psychiatry** 1985 Oct;142(10):1228-9

Opposite effects of chronic imipramine treatment on brain and urine MHPG levels in the rat. Sedlock ML, et al. **Biol Psychiatry** 1985 Aug; 20(8):858-65

Lack of effect of oral activated charcoal on imipramine clearance. Goldberg MJ, et al. **Clin Pharmacol Ther** 1985 Sep;38(3):350-3

Pharmacokinetics of imipramine and its major metabolites in pregnant rats and their fetuses following a single dose. DeVane CL, et al. **Drug Metab Dispos** 1985 Jul-Aug;13(4):438-42

2-Nitroimipramine: a photoaffinity probe for the serotonin uptake/tricyclic binding site complex. Wennogle LP, et al. **EMBO J** 1985 Apr;4(4):971-7

Involvement of amygdaloid catecholaminergic mechanism in suppressive effects of desipramine and imipramine on duration of immobility in rats forced to swim. Araki H, et al. **Eur J Pharmacol** 1985 Jul 31; 113(3):313-8

Effects of imipramine on behavior and brain norepinephrine metabolism in tetrabenazine treated rats: comparative study of a single administration with repeated administrations of imipramine. Hori A, et al. **Folia Psychiatr Neurol Jpn** 1983;37(4):465-74

Cerebrospinal fluid levels of amitriptyline, nortriptyline, imipramine and desmethylimipramine. Relationship to plasma levels and treatment outcome. Hanin I, et al. **J Affective Disord** 1985 Jul;9(1):69-78

Determination of cianopramine in human plasma by high-performance liquid chromatography and gas-liquid chromatography with ultraviolet, fluorescence and electron-capture detection. Hojabri H, et al. **J Chromatogr** 1985 Jul 12;342(1):97-103

The effects of chlorpromazine and imipramine on rate and stimulus control of matching to sample. Newland MC, et al. **J Exp Anal Behav** 1985 Jul;44(1):49-68

Elevated density of [3H]imipramine binding in aged human brain. Severson JA, et al. **J Neurochem** 1985 Nov;45(5):1382-9

Repeated treatment with imipramine or amitriptyline increases the locomotor response of rats to (+)-amphetamine given into the nucleus accumbens. Maj J, et al. **J Pharm Pharmacol** 1985 May;37(5):362-4

Effect of imipramine and adrenocorticotropin administration on the rat brain norepinephrine-coupled cyclic nucleotide generating system: alterations in alpha and beta adrenergic components. Duman RS, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):409-14

Biochemical and diagnostic classification and serum drug levels: relation to antidepressive effect of imipramine. Møller SE, et al. **Neuropsychobiology** 1985;13(4):160-6

Antidepressant treatment of children: clinical relapse is unrelated to tricyclic plasma concentrations. Olig RM, et al. **Percept Mot Skills** 1985 Jun;60(3):879-89

Serotonin uptake and imipramine binding in rat platelets after chronic dexamethasone and amitriptyline treatment. Chan MY, et al. **Pharmacol Res Commun** 1985 Jul;17(7):619-32

The acute and the chronic effects of imipramine on the spontaneous motility in chick embryos. Sedláček J. **Physiol Bohemoslov** 1985; 34(3):225-34

Imipramine for treatment of chronic depression. Kocsis JH, et al. **Psychopharmacol Bull** 1985;21(3):698-700

Addition of estrogen to imipramine in female-resistant depressives. Zohar J, et al. **Psychopharmacol Bull** 1985;21(3):705-6

Cianopramine and amitriptyline in the treatment of depressed patients—a placebo-controlled study. Hormazabal L, et al.

Psychopharmacology (Berlin) 1985;86(1-2):205-8

Ro 11-2465 (cyan-imipramine), citalopram and their N-desmethyl metabolites: effects on the uptake of 5-hydroxytryptamine and noradrenaline in vivo and related pharmacological activities. Pawlowski L, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):156-63

Repeated treatment with imipramine potentiates the locomotor effect of apomorphine administered into the hippocampus in rats. Smialowski A, et al. **Psychopharmacology (Berlin)** 1985;86(4):468-71

[Effect of antidepressive drugs and histamine H1 receptor blockaders on histamine level in rat brain] Zawilska J, et al. **Folia Med Cracov** 1984; 25(3-4):297-306 (Eng. Abstr.) **(Pol)**

[Inhibitors of reverse serotonin uptake and of specific imipramine binding in human blood plasma] Brusov OS, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):26-8 (Eng. Abstr.) **(Rus)**

[Isolation of substances inhibiting the specific binding of imipramine and serotonin uptake from the brain of the bull] Mukhin AG, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):197-9 (Eng. Abstr.) **(Rus)**

[Autoradiographic study of the ontogeny of the imipramine receptors in the cerebral cortex of rats] Pirogova MV, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):752-4 (Eng. Abstr.) **(Rus)**

INHIBITION (PSYCHOLOGY)

[Effect of a derivative of GABA, phenibut, on behavior and the activity of visual cortex neurons of the rabbit during elaboration of a defensive reflex and internal inhibition] Shul'gina GI, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):695-702 (Eng. Abstr.)**(Rus)**

INTERVIEW, PSYCHOLOGICAL

The clinical interview for depression. Development, reliability and validity. Paykel ES. **J Affective Disord** 1985 Jul;9(1):85-96

ISOCARBOXAZID

Monoamine oxidase inhibitor therapy for anorexia nervosa and bulimia: a preliminary trial of isocarboxazid. Kennedy SH, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):279-85

LACTATES

Further studies on reflectometric monitoring of cerebrocortical microcirculation. Importance of lactate anions in coupling between cerebral blood flow and metabolism. Dóra E. **Acta Physiol Hung** 1985; 66(2):199-211

Lactate-induced panic attacks: possible involvement of serotonin reuptake stimulation. Lingjaerde O. **Acta Psychiatr Scand** 1985 Aug; 72(2):206-8

[Synthesis of tyrosine and 3,4-dihydroxyphenylalanine by Citrobacter freundii bacteria from lactic acid] Kupletskaia MB. **Prikl Biokhim Mikrobiol** 1985 May-Jun;21(3):342-8 (Eng. Abstr.) **(Rus)**

LEARNING

Amygdala norepinephrine involved in two separate long-term memory retrieval processes. Ellis ME. **Brain Res** 1985 Sep 2;342(1):191-5

Genetic dissection of Drosophila adenylate cyclase. Livingstone MS. **Proc Natl Acad Sci USA** 1985 Sep;82(17):5992-6

Association between learning and cortical catecholamines in non-drug-treated rats. Sahakian BJ, et al. **Psychopharmacology (Berlin)** 1985;86(3):339-43

[Effect of a derivative of GABA, phenibut, on behavior and the activity of visual cortex neurons of the rabbit during elaboration of a defensive reflex and internal inhibition] Shul'gina GI, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):695-702 (Eng. Abstr.)**(Rus)**

LEVODOPA

Suppression of MPTP-induced dopaminergic neurotoxicity in mice by nomifensine and L-DOPA. Melamed E, et al. **Brain Res** 1985 Sep 9; 342(2):401-4

[Behavior disorder in rats induced by Madopar and its pharmacological correction] Bondarenko NA, et al. **Farmakol Toksikol** 1985 Jul-Aug; 48(4):31-4 (Eng. Abstr.) **(Rus)**

LH

Sexual differences in the effect of serotonin on LH secretion in rats. Moguilevsky JA, et al. **Acta Endocrinol (Copenh)** 1985 Jul; 109(3):320-5

Effect of pretreatment of long-term ovariectomized (OVX) rats with a competitive LRH antagonist on FSH release in vitro. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):481-4

Differential effects of forskolin on LH and GH release. Evans WS, et al. **Am J Physiol** 1985 Oct;249(4 Pt 1):E392-7

LH response to LH-RH neonatally estrogenized male rats. Pinilla L, et al. **Andrologia** 1985 May-Jun;17(3):254-6

Plasma FSH and LH in prepubertal Booroola ewe lambs. Bindon BM, et al. **Aust J Biol Sci** 1985;38(2):215-20

Pulsatile administration of gonadotropin-releasing hormone to anestrous sows: endocrine changes associated with GnRH-induced and spontaneous estrus. Armstrong JD, et al. **Biol Reprod** 1985 Sep; 33(2):375-80

A suppression of gonadotropin secretion by cortisol in castrated male rhesus monkeys (Macaca mulatta) mediated by the interruption of hypothalamic gonadotropin-releasing hormone release. Dubey AK, et al. **Biol Reprod** 1985 Sep;33(2):423-31

The effects of cycloheximide on in vitro response of Rana pipiens pituitaries to continuously superfused gonadotropin-releasing hormone. Porter DA. **Biol Reprod** 1985 Sep;33(2):393-400

Thyrotropin and gonadotropin releasing hormones (TRH and GnRH) do not alter levels of oxytocin and oxytocin does not change the response of luteinizing or follicle stimulating hormones to GnRH in humans. Amico JA, et al. **Endocr Res** 1985;11(1-2):75-85

Vasoactive intestinal polypeptide effects a central inhibition of pulsatile luteinizing hormone secretion in ovariectomized rats. Alexander MJ, et al. **Endocrinology** 1985 Nov;117(5):2134-9

Differential secretion of O-glycosylated gonadotropin alpha-subunit and luteinizing hormone (LH) in the presence of LH-releasing hormone. Corless CL, et al. **Endocrinology** 1985 Oct;117(4):1699-706

Effects of ovarian hormones on the concentrations of immunoreactive neuropeptide Y in discrete brain regions of the female rat: correlation with serum luteinizing hormone (LH) and median eminence LH-releasing hormone. Crowley WR, et al. **Endocrinology** 1985 Sep; 117(3):1151-5

Differential regulation of pulsatile luteinizing hormone (LH) and follicle-stimulating hormone secretion in ovariectomized rats disclosed by treatment with a LH-releasing hormone antagonist and phenobarbital. De Paolo LV. **Endocrinology** 1985 Nov; 117(5):1826-33

Corelease of dynorphin-like immunoreactivity, luteinizing hormone, and follicle-stimulating hormone from rat adenohypophysis in vitro. Knepel W, et al. **Endocrinology** 1985 Aug;117(2):481-7

In vivo gonadotropin-releasing hormone release and serum luteinizing hormone measurements in ovariectomized, estrogen-treated rhesus macaques. Levine JE, et al. **Endocrinology** 1985 Aug;117(2):711-21

Synthesis and release of luteinizing hormone in vitro by rat anterior pituitary cells: effects of gallopamil hydrochloride (D600) and pimozide. Liu TC, et al. **Endocrinology** 1985 Oct;117(4):1608-14

Secretion of ovine luteinizing hormone in vitro: differential positive control by 17 beta-estradiol and a preparation of porcine ovarian inhibin. Miller WL, et al. **Endocrinology** 1985 Sep;117(3):907-11

Effects of glucocorticoids on responsiveness of luteinizing hormone and follicle-stimulating hormone to gonadotropin-releasing hormone by male rat pituitary cells in vitro. Suter DE, et al. **Endocrinology** 1985 Sep;117(3):855-9

Effects of glucocorticoids on secretion of luteinizing hormone and follicle-stimulating hormone by female rat pituitary cells in vitro. Suter DE, et al. **Endocrinology** 1985 Sep;117(3):849-54

Gonadotropin-releasing hormone pulses in third ventricular cerebrospinal fluid of ovariectomized rhesus monkeys: correlation with luteinizing hormone pulses. Van Vugt DA, et al. **Endocrinology** 1985 Oct; 117(4):1550-8

Sex-specific effects of estradiol on hypothalamic noradrenaline turnover in gonadectomized rats. Hiemke C, et al. **Exp Brain Res** 1985; 59(1):68-72

Quinolinic acid stimulates luteinizing hormone secretion through a serotonin-dependent mechanism. Johnson MD, et al. **Exp Brain Res** 1985;59(1):62-7

The effect of delta 1tetrahydrocannabinol on luteinizing hormone release in castrated and hypothalamic deafferented male rats. Puder M, et al. **Exp Brain Res** 1985;59(2):213-6

Clomiphene citrate can mimic the augmentative (positive) but not the depressing (negative) effect of estradiol on the LHRH-stimulated release of LH and FSH by the pituitary gland of the long-term ovariectomized rat. Schuiling GA, et al. **Experientia** 1985 Aug 15;41(8):1060-3

Serum luteinizing hormone-releasing hormone (LH-RH) and gonadotropic hormones in men after a bolus dose of LH-RH: comparison of different doses and routes of administration. Fauser BC, et al. **Fertil Steril** 1985 Sep;44(3):384-9

The influence of thyrotropin releasing hormone on in vivo prolactin release and in vitro prolactin, luteinizing hormone, and growth hormone release from dispersed pituitary cells of the young turkey (Meleagris gallopavo). Fehrer SC, et al. **Gen Comp Endocrinol** 1985 Jul; 59(1):64-72

Hypothalamic and serum factors influence on prolactin and luteinizing hormone release by the pituitary gland of the young turkey (Meleagris gallopavo). Fehrer SC, et al. **Gen Comp Endocrinol** 1985 Jul; 59(1):73-81

Effects of chicken (Gln8)- and mammalian (Arg8)-luteinizing hormone-releasing hormones on the release of gonadotrophins in vitro and in vivo from the adenohypophysis of Japanese quail. Hattori A, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):155-61

LH secretion in response to gonadotropin releasing hormone (GnRH) by superfused pituitaries from two species of turtles. Licht P, et al. **Gen Comp Endocrinol** 1985 Sep;59(3):442-8

Pituitary responsiveness to superfused GnRH in two species of ranid frogs. Porter DA, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):308-15

Relationship between release of LH and incorporation of tritiated thymidine in the anterior pituitary gland of the castrated female rat. Machiavelli GA, et al. **Horm Metab Res** 1985 Jun;17(6):298-300

Effects of dihydrotestosterone benzoate administration on gonadotropin secretion in ovariectomized pony mares. Garza F Jr, et al. **J Anim Sci** 1985 Jul;61(1):240-4

Changes of luteinizing hormone and progesterone for dairy cows after gonadotropin-releasing hormone at first postpartum breeding. Lee CN, et al. **J Dairy Sci** 1985 Jun;68(6):1463-70

Changes in pituitary responsiveness to LH-releasing hormone after acute buserelin treatment: a time-course and dose-response study. Heather JD, et al. **J Endocrinol** 1985 Jul;106(1):27-30

The role of microfilaments in the priming effect of LH-releasing hormone: an ultrastructural study using cytochalasin B. Lewis CE, et al. **J Endocrinol** 1985 Aug;106(2):211-8

Differential effects of melatonin on the stimulated release of LH from dispersed pituitary cells of the prepubertal female rat. Symons AM, et al. **J Endocrinol** 1985 Oct;107(1):107-12

LH bioactivity in male puberty and senescence. Montanini V, et al. **J Endocrinol Invest** 1984;7 Suppl 3:43-52

The effect of ovine pineal compounds prepared under red or green light on the activity of male rat anterior pituitaries in vitro. Slama-Scemama A, et al. **J Neural Transm** 1985;62(1-2):155-67

Time series analysis of plasma LH and FSH concentrations as a method of assessing episodic secretion. McLeod BJ, et al. **J Reprod Fertil** 1985 Jul;74(2):575-87

Plasma LH and FSH responses and ovarian activity in prepubertal heifers treated with repeated injections of low doses of GnRH for 72 h. McLeod BJ, et al. **J Reprod Fertil** 1985 Jul;74(2):589-96

Comparison of the effects of neuropeptide Y and adrenergic transmitters on LH release and food intake in male rats. Allen LG, et al. **Life Sci** 1985 Aug 19;37(7):617-23

Effects of the 1,5-benzodiazepine clobazam on pituitary hormones in the male rat. Valli M, et al. **Methods Find Exp Clin Pharmacol** 1985 Apr;7(4):179-81

A prolactin-inhibiting factor within the precursor for human gonadotropin-releasing hormone. Nikolics K, et al. **Nature** 1985 Aug 8-14;316(6028):511-7

Further studies on the effects of testosterone on hypothalamic LH-RH and serum LH levels: castration-induced delayed response. Kalra PS. **Neuroendocrinology** 1985 Sep;41(3):219-23

Effect of histamine on basal and TRH/LH-RH-stimulated PRL and LH secretion during different phases of the menstrual cycle in normal women. Knigge U, et al. **Neuroendocrinology** 1985 Oct;41(4):337-41

Effects of endogenous opioid peptides and opiates on luteinizing hormone and prolactin secretion in ovariectomized rats. Leadem CA, et al. **Neuroendocrinology** 1985 Oct;41(4):342-52

Ovarian steroid regulation of pulsatile luteinizing hormone release during the interval between the mornings of diestrus 2 and proestrus in the rat. Leipheimer RE, et al. **Neuroendocrinology** 1985 Sep;41(3):252-7

Estradiol-induced LH release in juvenile female rats: nembutal blocks both the decline and the exposure of nonavailable pituitary LHRH receptor sites. Smith SS, et al. **Neuroendocrinology** 1985 Sep;41(3):246-51

Interaction between the posterior pituitary and LHRH in the control of LH secretion. Froehlich JC, et al. **Peptides (Fayetteville)** 1985;6 Suppl 1:127-31

The influence of pharmacological manipulation of serotonin on serum growth hormone and luteinizing hormone levels in young turkeys (Meleagris gallopavo). Fehrer SC, et al. **Poult Sci** 1985 Jul;64(7):1356-62

LH-RH antagonists--mechanisms of action. van Rees GP. **Prog Clin Biol Res** 1985;185A:155-9

Role of brain epinephrine neurons in the regulation of serum prolactin and luteinizing hormone release in female rats. Liang NY, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jun;48(3):459-62

[Gonadotropin stimulation during LH/RH analog-induced inhibition of pituitary function] Bettendorf G, et al. **Geburtshilfe Frauenheilkd** 1985 Jul;45(7):431-7 (Eng. Abstr.) **(Ger)**

[Effect of gonadectomy and luliberin on the gonadotropic function of the hypophysis in Papio hamadryas] Katsiia GV, et al. **Probl Endokrinol (Mosk)** 1985 Jul-Aug;31(4):55-8 (Eng. Abstr.)**(Rus)**

[Correlation between the thyroxine, 17-beta-estradiol and luteinizing hormones in the systemic circulation and the rectal and vaginal temperature in heifers and cows after administration of cloprostenol] Elečko J, et al. **Vet Med (Praha)** 1985 May;30(5):257-66 (Eng. Abstr.) **(Slo)**

LH-FSH RELEASING HORMONE

Effect of pretreatment of long-term ovariectomized (OVX) rats with a competitive LRH antagonist on FSH release in vitro. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):481-4

LH response to LH-RH neonatally estrogenized male rats. Pinilla L, et al. **Andrologia** 1985 May-Jun;17(3):254-6

LHRH self-priming in the male: effect of multiple priming injections in the immature rat. Nazian SJ. **Arch Androl** 1984;13(2-3):241-4

Pregnancy rate of cows given synthetic gonadotrophin-releasing hormone at the time of service. Anderson GA, et al. **Aust Vet J** 1985 Jul;62(7):222-4

Luteinizing hormone-releasing hormone enhances polyphosphoinositide breakdown in rat granulosa cells. Ma F, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1201-8

Identification and partial characterization of gonadotropin-releasing hormone-like factors in human seminal plasma. Sokol RZ, et al. **Biol Reprod** 1985 Sep;33(2):370-4

Conjugated catecholamines and pressor responses to angiotensin, luteinizing hormone-releasing hormone and prazosin in conscious toads. Wilson JX. **Br J Pharmacol** 1985 Jul;85(3):647-53

Combined electrophysiological, immunocytochemical and peptide release measurements in the hypothalamic slice. Kelly MJ, et al. **Brain Res** 1985 Oct 21;345(2):264-70

Dibutyryl cyclic adenosine monophosphate stimulates in vitro luteinizing hormone-releasing hormone release only from median eminence derived from ovariectomized, estradiol-primed rats. Kim K, et al. **Brain Res** 1985 Sep 2;342(1):154-7

The LH-RH-containing neuronal network in the preoptic area of the rat: demonstration of LH-RH-containing nerve terminals in synaptic contact with LH-RH neurons. Leranth C, et al. **Brain Res** 1985 Oct 21;345(2):332-6

LH-RH analogue acts as substance P antagonist by inhibiting spinal cord vasomotor responses. Takano Y, et al. **Brain Res** 1985 Jul 1;337(2):357-61

Gonadotropin-releasing hormone-immunoreactive neuronal structures in the brain and pituitary of the African catfish, Clarias gariepinus (Burchell). Goos HJ, et al. **Cell Tissue Res** 1985;241(3):593-6

Thyrotropin and gonadotropin releasing hormones (TRH and GnRH) do not alter levels of oxytocin and oxytocin does not change the response of luteinizing or follicle stimulating hormones to GnRH in humans. Amico JA, et al. **Endocr Res** 1985;11(1-2):75-85

Gonadotropin-releasing hormone induces classical meiotic maturation in subpopulations of atretic preantral follicles. Banka CL, et al. **Endocrinology** 1985 Oct;117(4):1500-7

Progesterone decreases the responsiveness of ovine pituitary cultures to luteinizing hormone-releasing hormone. Batra SK, et al. **Endocrinology** 1985 Oct;117(4):1436-40

Differential secretion of O-glycosylated gonadotropin alpha-subunit and luteinizing hormone (LH) in the presence of LH-releasing hormone. Corless CL, et al. **Endocrinology** 1985 Oct;117(4):1699-706

Effects of ovarian hormones on the concentrations of immunoreactive neuropeptide Y in discrete brain regions of the female rat: correlation with serum luteinizing hormone (LH) and median eminence LH-releasing hormone. Crowley WR, et al. **Endocrinology** 1985 Sep;117(3):1151-5

Differential regulation of pulsatile luteinizing hormone (LH) and follicle-stimulating hormone secretion in ovariectomized rats disclosed by treatment with a LH-releasing hormone antagonist and phenobarbital. De Paolo LV. **Endocrinology** 1985 Nov;117(5):1826-33

Hyperprolactinemia inhibits gonadotropin-releasing hormone (GnRH) stimulation of the number of pituitary GnRH receptors. Garcia A, et al. **Endocrinology** 1985 Sep;117(3):954-9

Photoaffinity labeling of pituitary and gonadal receptors for gonadotropin-releasing hormone. Iwashita M, et al. **Endocrinology** 1985 Aug;117(2):738-46

In vivo gonadotropin-releasing hormone release and serum luteinizing hormone measurements in ovariectomized, estrogen-treated rhesus macaques. Levine JE, et al. **Endocrinology** 1985 Aug;117(2):711-21

Luteinizing hormone-releasing hormone stimulates arachidonic acid release in rat granulosa cells. Minegishi T, et al. **Endocrinology** 1985 Nov;117(5):2001-7

Stimulation of cyclic adenosine 3',5'-monophosphate production enhances hypothalamic luteinizing hormone-releasing hormone release without increasing prostaglandin E2 synthesis: studies in prepubertal female rats. Ojeda SR, et al. **Endocrinology** 1985 Sep;117(3):1175-8

Gonadotropin-releasing hormone pulses in third ventricular cerebrospinal fluid of ovariectomized rhesus monkeys: correlation with luteinizing hormone pulses. Van Vugt DA, et al. **Endocrinology** 1985 Oct;117(4):1550-8

Immunoreactive substance P and LH-RH content in median eminence and pituitary gland during proestrus, oestrus, lactation and after anterior hypothalamic deafferentation. Jakubowska-Naziemblo B, et al. **Exp Clin Endocrinol** 1985 Apr;85(2):155-66

Serum luteinizing hormone-releasing hormone (LH-RH) and gonadotropic hormones in men after a bolus dose of LH-RH: comparison of different doses and routes of administration. Fauser BC, et al. **Fertil Steril** 1985 Sep;44(3):384-9

Immunocytochemistry of luteinizing hormone-releasing hormone and sexual maturation of the frog brain: comparisons of juvenile and adult bullfrogs (Rana catesbeiana). Crim JW. **Gen Comp Endocrinol** 1985 Sep; 59(3):424–33

Effects of chicken (Gln8)- and mammalian (Arg8)-luteinizing hormone-releasing hormones on the release of gonadotrophins in vitro and in vivo from the adenohypophysis of Japanese quail. Hattori A, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):155–61

An immunohistochemical study of seasonal changes in luteinizing hormone-releasing hormone and vasotocin in the forebrain and the neurohypophysis of the toad, Bufo japonicus. Jokura Y, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):238–45

Pituitary responsiveness to superfused GnRH in two species of ranid frogs. Porter DA, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):308–15

Direct effect of the luteinizing hormone releasing hormone analog D-Trp6-Pro9-Net-LHRH on rat ovarian steroidogenesis. Malozowski S, et al. **Horm Metab Res** 1985 Jun;17(6):321–2

Specific binding of gonadotrophin-releasing hormone and an agonist to human corpus luteum homogenates: characterization, properties, and luteal phase levels. Bramley TA, et al. **J Clin Endocrinol Metab** 1985 Nov;61(5):834–41

Pulsatile gonadotropin secretion in women with hypothalamic amenorrhea: evidence that reduced frequency of gonadotropin-releasing hormone secretion is the mechanism of persistent anovulation. Reame NE, et al. **J Clin Endocrinol Metab** 1985 Nov;61(5):851–8

Ontogenesis of neurons producing luteinizing hormone-releasing hormone (LHRH) in the nervus terminalis of the rat. Schwanzel-Fukuda M, et al. **J Comp Neurol** 1985 Aug 15;238(3):348–64

Changes in pituitary responsiveness to LH-releasing hormone after acute buserelin treatment: a time-course and dose-response study. Heather JD, et al. **J Endocrinol** 1985 Jul;106(1):27–30

Pituitary receptors for LH-releasing hormone (LHRH) and responsiveness to LHRH in adult female rats after neonatal monosodium L-glutamate treatment. Inkster SE, et al. **J Endocrinol** 1985 Oct; 107(1):9–13

Effects of dopamine and morphine on immunoreactive somatostatin and LH-releasing hormone secretion from hypothalamic fragments in vitro. Lengyel AM, et al. **J Endocrinol** 1985 Sep;106(3):317–22

The role of microfilaments in the priming effect of LH-releasing hormone: an ultrastructural study using cytochalasin B. Lewis CE, et al. **J Endocrinol** 1985 Aug;106(2):211–8

Effects of LH-releasing hormone antagonist or lesions of the medial basal hypothalamus on periovulatory gonadotrophin release in female rats. Rush ME. **J Endocrinol** 1985 Sep;106(3):361–6

Pituitary gonadotrophin-releasing hormone receptor up-regulation in vitro: dependence on calcium and microtubule function. Young LS, et al. **J Endocrinol** 1985 Oct;107(1):49–56

The effect of ovine pineal compounds prepared under red or green light on the activity of male rat anterior pituitaries in vitro. Slama-Scemama A, et al. **J Neural Transm** 1985;62(1–2):155–67

Release of LHRH in vitro and anterior pituitary responsiveness to LHRH in vivo during sexual maturation in pullets (Gallus domesticus). Knight PG, et al. **J Reprod Fertil** 1985 May;74(1):145–51

Long-term reversible suppression of oestrus in bitches with nafarelin acetate, a potent LHRH agonist. McRae GI, et al. **J Reprod Fertil** 1985 Jul;74(2):389–97

The effects of thymus-derived peptides on hypothalamic LRF and pituitary gonadotropin content in prepubertal congenitally athymic nude mice and their normal heterozygous littermates. Strich G, et al. **J Reprod Immunol** 1985 Jun;7(4):351–9

Reproductive/endocrine and anaphylactoid properties of an LHRH-antagonist, ORF 18260 [Ac-DNAL1(2), 4FDPhe2,D-Trp3,D-Arg6]-GnRH. Hahn DW, et al. **Life Sci** 1985 Aug 12;37(6):505–14

Stimulation and inhibition of Leydig cell steroidogenesis by the phorbol ester 12-O-tetradecanoylphorbol 13-acetate: similarity to the effects of gonadotropin-releasing hormone. Moger WH. **Life Sci** 1985 Sep 2; 37(9):869–73

Enzymatic tracer damage during the gonadotropin releasing hormone radioimmunoassay: analytical and immunological assessment. O'Conner JL, et al. **Life Sci** 1985 Sep 23;37(12):1155–65

Effect of an intranasal LHRH agonist on gonadotrophins and hot flushes in post-menopausal women. Shaw RW, et al. **Maturitas** 1985 Jul; 7(2):161–7

The mechanisms of LHRH agonist action in gonadal tissues. Cooke BA, et al. **Mol Cell Endocrinol** 1985 Jul;41(2–3):115–22 (68 ref.)

Has the prolactin inhibiting peptide at last been found? [news] Fink G. **Nature** 1985 Aug 8–14;316(6028):487–8

A prolactin-inhibiting factor within the precursor for human gonadotropin-releasing hormone. Nikolics K, et al. **Nature** 1985 Aug 8–14;316(6028):511–7

Immunocytochemical localization in rat brain of a prolactin release-inhibiting sequence of gonadotropin-releasing hormone prohormone. Phillips HS, et al. **Nature** 1985 Aug 8–14; 316(6028):542–5

Effects of advancing age on hypothalamic neurotransmitter content and on basal and norepinephrine-stimulated LHRH release. Steger RW, et al. **Neurobiol Aging** 1985 Summer;6(2):113–6

Castration of male rats reduces the capacity of granules isolated from the median eminence to secrete luteinizing hormone-releasing hormone in response to copper. Barnea A, et al. **Neuroendocrinology** 1985 Aug; 41(2):149–55

Hormonal modulation of the responsiveness of midbrain central gray neurons to LH-RH. Chan A, et al. **Neuroendocrinology** 1985 Aug; 41(2):163–8

Further studies on the effects of testosterone on hypothalamic LH-RH and serum LH levels: castration-induced delayed response. Kalra PS. **Neuroendocrinology** 1985 Sep;41(3):219–23

Effect of histamine on basal and TRH/LH-RH-stimulated PRL and LH secretion during different phases of the menstrual cycle in normal women. Knigge U, et al. **Neuroendocrinology** 1985 Oct;41(4):337–41

Ovarian LHRH receptors increase following lesions of the major LHRH structures in the rat brain: involvement of a direct neural pathway. Marchetti B, et al. **Neuroendocrinology** 1985 Oct;41(4):321–31

Progesterone and the control of functional luteolysis, of secretion of prolactin and of pituitary LHRH responsiveness. A study with pseudopregnant rats kept in alternating and constant lighting conditions. Schuiling GA, et al. **Neuroendocrinology** 1985 Jul;41(1):52–9

Estradiol-induced LH release in juvenile female rats: nembutal blocks both the decline and the exposure of nonavailable pituitary LHRH receptor sites. Smith SS, et al. **Neuroendocrinology** 1985 Sep; 41(3):246–51

Interaction between the posterior pituitary and LHRH in the control of LH secretion. Froehlich JC, et al. **Peptides (Fayetteville)** 1985; 6 Suppl 1:127–31

Methods for the isolation of viable gonadotropin-releasing hormone (LRF) neurons. Melrose PA, et al. **Peptides (Fayetteville)** 1985 Mar–Apr; 6(2):347–51

[Trp7,Leu8]LH-RH in reptilian brain. Powell RC, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):223–7

Synaptology of luteinizing hormone-releasing hormone neurons in rat preoptic area. Witkin JW, et al. **Peptides (Fayetteville)** 1985 Mar–Apr; 6(2):263–71

LHRH and mating behavior: sexual receptivity versus sexual preference. Dudley CA, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):967–72

LH-RH antagonists--mechanisms of action. van Rees GP. **Prog Clin Biol Res** 1985;185A:155–9

LIPOTROPIN

Light and electron microscopic immunocytochemistry of beta-endorphin/beta-LPH-like immunoreactive neurons in the arcuate nucleus and surrounding areas of the rat hypothalamus. Ibata Y, et al. **Brain Res** 1985 Aug 26;341(2):233–42

The effect of various corticotropin-releasing factor trains on the release of adrenocorticotropin, beta-endorphin, and beta-lipotropin from perifused ovine pituitary cells. Evans MJ, et al. **Endocrinology** 1985 Sep;117(3):893–9

[Biosynthesis of pro-opiomelanocortin and secretion of its fragments by cultured bone marrow cells of mice] Dmitriev AD, et al. **Dokl Akad Nauk SSSR** 1985 May–Jun;282(1):199–202 **(Rus)**

LITHIUM

Ocular effects of oral lithium in humans. Kaufman PL, et al. **Acta Ophthalmol (Copenh)** 1985 Jun;63(3):327–32

Effects of acute and short-time antibiotic treatment on renal lithium elimination and serum lithium levels in the rat. Lassen E. **Acta Pharmacol Toxicol (Copenh)** 1985 Apr;56(4):273–7

Effects of histamine and H1 and H2-receptor antagonists on the wet-dog-shaking episodes in rats induced with lithium chloride. Rajtar G, et al. **Acta Physiol Pol** 1984 Mar–Apr;35(2):131–5

Long-term lithium prophylaxis in recurrent unipolar depression. A controversial indication? Lepkifker E, et al. **Acta Psychiatr Belg** 1985 May–Jun;85(3):434–43

Clinical and laboratory effects of discontinuation of lithium prophylaxis. Goodnick PJ. **Acta Psychiatr Scand** 1985 Jun;71(6):608–14

Lithium effects on ophthalmological-electrophysiological parameters in young healthy volunteers. Ullrich A, et al. **Acta Psychiatr Scand** 1985

Aug;72(2):113-9

Response to lithium prophylaxis in schizoaffective psychoses. Kemali D, et al. **Adv Biochem Psychopharmacol** 1985;40:153-8

Research overview of drug therapy in recurrent and chronic depression. Prien RF. **Adv Biochem Psychopharmacol** 1985;40:121-30

Practical problems of lithium maintenance treatment. Schou M. **Adv Biochem Psychopharmacol** 1985;40:131-8

Modification of urinary potassium secretion following lithium in rats of different ages. Kersten L, et al. **Agressologie** 1985 Mar;26(3):253-6

Nonspecific stomatitis due to lithium therapy [letter] Bar Nathan EA, et al. **Am J Psychiatry** 1985 Sep;142(9):1126-7

A lithium-tricyclic combination for treatment of depression [letter] Pande AD, et al. **Am J Psychiatry** 1985 Oct;142(10):1228-9

Matrix modifiers in graphite furnace atomic absorption analysis of trace lithium in biological fluids. Trapp GA. **Anal Biochem** 1985 Jul; 148(1):127-32

Determination of lithium, rubidium and strontium in foodstuffs. Evans WH, et al. **Analyst** 1985 Jun;110(6):619-23

Effect of lithium treatment on blood pressure and angiotensin-converting enzyme activity in normotensive Wistar-Kyoto and spontaneously hypertensive rats. Das S, et al. **Arch Int Pharmacodyn Ther** 1985 Jul; 276(1):82-91

Lipid peroxidation as a possible mechanism for the neurotoxic and nephrotoxic effects of a combination of lithium carbonate and haloperidol. Sawas AH, et al. **Arch Int Pharmacodyn Ther** 1985 Aug; 276(2):301-12

Salt-dependent structural changes of neurohormones: lithium ions induce conformational rearrangements of ocytocin to a vasopressin-like structure. Rholam M, et al. **Biochemistry** 1985 Jun 18;24(13):3345-9

Changes in the diagnoses of the functional psychoses associated with the introduction of lithium. Parker G, et al. **Br J Psychiatry** 1985 Apr; 146:377-82

Neuroleptics, lithium and renal function. Waller DG, et al. **Br J Psychiatry** 1985 May;146:510-4

The role of lithium carbonate in the management of hemolymphoblastosis: estimation of plasmatic and erythrocyte lithium levels. Fanci R, et al. **Chemioterapia** 1985 Jun;4(3):260-4

Short-term lithium administration enhances serotonergic neurotransmission: electrophysiological evidence in the rat CNS. Blier P, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):69-77

Energy response of LiF (TLD-100) and CaSO4:Dy TL dosimeters to different diagnostic spectra. Servomaa AJ. **Eur J Radiol** 1985 Aug; 5(3):236-9

Lithium intolerance disproved by blind clinical trial. Kellner CH, et al. **Hillside J Clin Psychiatry** 1985;7(1):82-7

Slow-release lithium in treatment of schizoaffective syndromes. Romeo R, et al. **Int J Clin Pharmacol Res** 1985;5(3):205-11

Variation in the relationship between serum and saliva lithium levels. Sankaranarayanan A, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Jul;23(7):365-6

Lithium prophylaxis of recurrent affective disorders. Glen AI. **J Affective Disord** 1985 May-Jun;8(3):259-65

Lithium dosage in the elderly. A study with matched age groups. Greil W, et al. **J Affective Disord** 1985 Jul;9(1):1-4

Lithium in the treatment of mania. Tyrer SP. **J Affective Disord** 1985 May-Jun;8(3):251-7

The neurochemistry of mania. The effect of lithium on catecholamines, indoleamines and calcium mobilization. Wood K. **J Affective Disord** 1985 May-Jun;8(3):215-23

Lichenoid stomatitis associated with lithium carbonate. Hogan DJ, et al. **J Am Acad Dermatol** 1985 Aug;13(2 Pt 1):243-6

Interrelationships among quinidine, amiloride, and lithium as inhibitors of the renal Na+-H+ exchanger. Mahnensmith RL, et al. **J Biol Chem** 1985 Oct 15;260(23):12586-92

Lithium ion inhibits nerve growth factor-induced neurite outgrowth and phosphorylation of nerve growth factor-modulated microtubule-associated proteins. Burstein DE, et al. **J Cell Biol** 1985 Sep;101(3):862-70

Lithium Information Center: The Lithium Library revisited. Greist JH, et al. **J Clin Psychiatry** 1985 Aug;46(8):327-31

Selective transport of Li+ across lipid bilayer membranes mediated by an ionophore of novel design (ETH1644). Zeevi A, et al. **J Membr Biol** 1985;86(1):61-7

Differential effects of lithium on muscarinic receptor stimulation of inositol phosphates in rat cerebral cortex slices. Batty I, et al. **J Neurochem** 1985 Nov;45(5):1514-21

Intrinsic dissolution of lithium carbonate in aqueous solutions. Wall BP, et al. **J Pharm Pharmacol** 1985 May;37(5):338-40

Evidence for in vivo effect of lithium on p-aminohippurate transport in rat kidney, preliminary study. Sugihara K, et al. **Jpn J Pharmacol** 1985 Jun;38(2):127-32

Low dose lithium carbonate in the treatment of post traumatic stress disorder: brief communication. Kitchner I, et al. **Milit Med** 1985 Jul; 150(7):378-81

Effect of chronic lithium administration on neurotransmitter metabolism in synaptosomes from rat brain. Rafałowska U, et al. **Neuropatol Pol** 1985;23(2):211-8

Erythrocyte differentiation of naturally occurring isotopic lithium abundances. Lieberman KW, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):145-6

Factors associated with response to lithium prophylaxis in DSM III major depression and bipolar disorder. Maj M, et al. **Pharmacopsychiatry** 1985 Sep;18(5):309-13

Renal function and enzymatic studies of the urine in patients on a long-term lithium therapy. Astrug A, et al. **Przegl Lek** 1985; 42(3):361-3

A controlled study of cellular immune function in affective disorders before and during somatic therapy. Albrecht J, et al. **Psychiatry Res** 1985 Jul;15(3):185-93

Serum lithium minimum and diuresis. Mellerup ET, et al. **Psychiatry Res** 1985 Apr;14(4):309-13

Mood-independent aberrancies in associative processes in bipolar affective disorder: an apparent stabilizing effect of lithium. Pons L, et al. **Psychiatry Res** 1985 Apr;14(4):315-22

Side-effects of lithium at lower therapeutic levels: the significance of thirst. King JR, et al. **Psychol Med** 1985 May;15(2):355-61

Investigating renal function during lithium treatment. Waller DG, et al. **Psychol Med** 1985 May;15(2):369-75

Influence of housing conditions and state of partner on conditioning and extinction of taste aversion to lithium and chlorpromazine. Giardini V. **Psychopharmacology (Berlin)** 1985;86(1-2):96-101

Cognitive effects of lithium treatment in normal volunteers. Weingartner H, et al. **Psychopharmacology (Berlin)** 1985;86(4):472-4

Inhibitory effect on lithium on p-aminohippurate transport in rat kidney cortex in vitro. Gemba M, et al. **Renal Physiol** 1985;8(3):179-88

Li+-induced release of the folate binding protein from human granulocytes. Holm J, et al. **Scand J Haematol** 1985 Jul; 35(1):109-14

[The prediction of therapeutic dosage of lithium] Zhang MY. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Aug; 17(4):239-41 (Eng. Abstr.) **(Chi)**

[Lithium levels in biological media and treatment surveillance] Greffe J, et al. **Encephale** 1985 Mar-Apr;11(2):79-83 (Eng. Abstr.) **(Fre)**

[Changes in cerebral calcium, sodium and potassium after single or repeated administration of lithium in the rat] Scotto di Tella AM, et al. **Encephale** 1985 Mar-Apr;11(2):53-6 (Eng. Abstr.) **(Fre)**

[Effect of lithium chloride on thyroid structural elements in the rat and on the balance of calcitropic hormones] Petrov NM, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):711-3 (Eng. Abstr.) **(Rus)**

[Combined action of lithium salts and serotonin on the caudate nucleus] Zamoshchina TA, et al. **Biull Eksp Biol Med** 1985 Aug; 100(8):191-3 (Eng. Abstr.) **(Rus)**

[Effectiveness of combined administration of lithium carbonate and prednisolone in neutropenias] Iavorkovskiĭ LL, et al. **Ter Arkh** 1985; 57(7):84-8 (Eng. Abstr.) **(Rus)**

[Family interactions and adherence to lithium pharmacotherapy] de León OA, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):7-16 (Eng. Abstr.) **(Spa)**

[Poisoning caused by lithium salts (letter)] Pérez Martínez JM, et al. **Med Clin (Barc)** 1985 Mar 30;84(12):500 **(Spa)**

[Nephrotic syndrome associated with lithium therapy (letter)] Rodríguez Jornet A, et al. **Med Clin (Barc)** 1985 Jun 15;85(3):125 **(Spa)**

LORAZEPAM

Task-dependent development of cross-tolerance to psychomotor effects of lorazepam in man. Aranko K. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):373-81

Parenteral premedication with lorazepam--a dose/response study. Odugbesan CO, et al. **Afr J Med Med Sci** 1985 Mar-Jun; 14(1-2):65-9

Lorazepam dependence and chronic psychosis [letter] Fraser AA, et al. **Br J Psychiatry** 1985 Aug;147:211

A multi-centre, double-blind parallel trial of bromazepam ('Lexotan') and lorazepam to compare the acute benefit-risk ratio in the treatment of patients with anxiety. Cordingley GJ, et al. **Curr Med Res Opin** 1985; 9(7):505-10

Sleep and wake after benzodiazepine hypnotics: a 20-hour EEG comparison of lormetazepam and flunitrazepam. Timsit-Berthier M, et al. **Curr Med Res Opin** 1985;9(8):552-9

Lorazepam--a benzodiazepine to choose or avoid? **Drug Ther Bull** 1985 Aug 12;23(16):61-2

Temporal variations of lorazepam pharmacokinetics. Bruguerolle B, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Jul;23(7):352-4

Probenecid impairment of acetaminophen and lorazepam clearance: direct inhibition of ether glucuronide formation. Abernethy DR, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):345-9

The influence of ritanserin, a serotonin antagonist, in anxiety disorders: a double-blind placebo-controlled study versus lorazepam. Ceulemans DL, et al. **Pharmacopsychiatry** 1985 Sep;18(5):303-5

Comparative pharmacokinetics and pharmacodynamics of lorazepam, alprazolam and diazepam. Ellinwood EH Jr, et al. **Psychopharmacology (Berlin)** 1985;86(4):392-9

[Temesta] Scottez B, et al. **Soins Psychiatr** 1985 May;(55):I-II **(Fre)**

[Importance of protein binding of lorazepam in its clinical management] Aguilera Celorrio L, et al. **Rev Esp Anestesiol Reanim** 1985 May-Jun; 32(3):115-8 (Eng. Abstr.) **(Spa)**

MANIC DISORDER

Plasma cortisol levels in mania: associated clinical ratings and changes during treatment with haloperidol. Cookson JC, et al. **Br J Psychiatry** 1985 May;146:498-502

The use of sodium valproate, carbamazepine and oxcarbazepine in patients with affective disorders. Emrich HM, et al. **J Affective Disord** 1985 May-Jun;8(3):243-50

Lithium prophylaxis of recurrent affective disorders. Glen AI. **J Affective Disord** 1985 May-Jun;8(3):259-65

Lithium in the treatment of mania. Tyrer SP. **J Affective Disord** 1985 May-Jun;8(3):251-7

The neurochemistry of mania. The effect of lithium on catecholamines, indoleamines and calcium mobilization. Wood K. **J Affective Disord** 1985 May-Jun;8(3):215-23

Sensation seeking, mania, and monoamines. Zuckerman M. **Neuropsychobiology** 1985;13(3):121-8

Erythrocyte differentiation of naturally occurring isotopic lithium abundances. Lieberman KW, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):145-6

[Manic decompensation] Lavoie JG. **Can J Psychiatry** 1985 Jun; 30(4):270-3 (Eng. Abstr.) **(Fre)**

[Therapy of depressive and manic diseases] Seige D. **Psychiatr Neurol Med Psychol Beih** 1966;4-5:186-92 **(Ger)**

[Parenteral form of pipothiazine in the treatment of endogenous psychoses] Matkowski K, et al. **Psychiatr Pol** 1984 Nov-Dec;18(6):567-70 (Eng. Abstr.) **(Pol)**

MATERNAL BEHAVIOR

Maternal aggression in mice: effects of treatments with PCPA, 5-HTP and 5-HT receptor antagonists. Ieni JR, et al. **Eur J Pharmacol** 1985 May 8;111(2):211-20

Maternal aggression in rats: effects of chlordiazepoxide and fluprazine. Olivier B, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):68-76

MEMORY

Memory effects of GABA-ergic antagonists in rats trained with two-way active avoidance tasks. Yonkov DI, et al. **Acta Physiol Pharmacol Bulg** 1985;11(2):44-9

Neocortical involvement in the acquisition and retention of learned alcohol aversions in rats. Kiefer SW, et al. **Alcohol** 1985 Jul-Aug; 2(4):597-601

Amygdala norepinephrine involved in two separate long-term memory retrieval processes. Ellis ME. **Brain Res** 1985 Sep 2;342(1):191-5

Converging sectors of psychoanalysis and neurobiology: mutual challenge and opportunity. Reiser MF. **J Am Psychoanal Assoc** 1985; 33(1):11-34

Blockade of peripheral beta-adrenergic receptors fails to suppress the cerebral spread of an engram in mice. Church AC, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):27-31

The conditioned place preference is affected by two independent reinforcement processes. White NM, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):37-42

Posterior hypothalamic deafferentation abolishes the amnestic effect of electroconvulsive shock in rats. Netto CA, et al. **Psychoneuroendocrinology** 1985;10(2):159-63

Memory enhancement: supra-additive effect of subcutaneous cholinergic drug combinations in mice. Flood JF, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):61-7

Effects of phenobarbital, clonazepam, valproic acid, ethosuximide, and phenytoin on the delayed matching-to-sample performance of pigeons. Picker M, et al. **Psychopharmacology (Berlin)** 1985;86(4):494-8

The effect of stimulus preexposure upon the context effect in taste-aversion learning in noradrenaline-depleted rats. Archer T, et al. **Scand J Psychol** 1985;26(2):158-69

[Effect of a cyclic analog of enkephalin on learning and memory in the mouse] Getsova VM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug; 35(4):710-7 (Eng. Abstr.) **(Rus)**

[Effect of noradrenaline, microapplied to the dorsal hippocampus of the rat, on conditioned reflex memory] Melikov EM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):780-2 **(Rus)**

MEMORY DISORDERS

Subjective memory complaints in geriatric depression. Plotkin DA, et al. **Am J Psychiatry** 1985 Sep;142(9):1103-5

MENTAL DISORDERS

Patient attitudes in short-term psychiatric care. Relations to social and psychiatric background, clinical symptoms, and treatment model. Hansson L, et al. **Acta Psychiatr Scand** 1985 Aug;72(2):193-201

Hair analysis for detection of phencyclidine in newly admitted psychiatric patients. Sramek JJ, et al. **Am J Psychiatry** 1985 Aug;142(8):950-3

Daily patterns of serotonin uptake in platelets from psychiatric patients and control volunteers. Humphries LL, et al. **Biol Psychiatry** 1985 Oct; 20(10):1073-81

Use of carbamazepine in psychiatric disorders. Birkhimer LJ, et al. **Clin Pharm** 1985 Jul-Aug;4(4):425-34

Service and patient predictors of continuation in clinic-based treatment. Atwood N, et al. **Hosp Community Psychiatry** 1985 Aug;36(8):865-9

An empirical view of patients exercising their right to refuse treatment. Bloom JD, et al. **Int J Law Psychiatry** 1984;7(3-4):315-28

Psychiatric treatment refusal, patient competence, and informed consent. Brown P. **Int J Law Psychiatry** 1986;8(1):83-94

The combination of psychiatric treatment and yoga. Nešpor K. **Int J Psychosom** 1985;32(2):24-7

Psychotropic drug use in older people: a review. Greene JA. **J Tenn Med Assoc** 1985 Jul;78(7):431-5

The pharmacokinetics of some psychoactive drugs and relationships to clinical response. Gottschalk LA. **Methods Find Exp Clin Pharmacol** 1985 May;7(5):275-82 (33 ref.)

The effect of milenperone on the aggressive behavior of psychogeriatric patients. A double-blind placebo-controlled study. De Cuyper H, et al. **Neuropsychobiology** 1985;13(1-2):1-6

Discussing issue of cost of drugs for the long term mentally ill. Roberts S. **Nurs Stand** 1985 Jul 4;(404):5

Planned change: an innovative nursing rehabilitation model. Bevvino CA, et al. **Perspect Psychiatr Care** 1984 Oct-Dec;22(4):149-58

A common single binding site for many psychotropic drugs on human alpha 1-acid glycoprotein. Therapeutically relevant observation? Müller WE. **Pharmacopsychiatry** 1985 Jul;18(4):257-8

Use of psychotropics in patients with kidney failure. Levy NB. **Psychosomatics** 1985 Sep;26(9):699-701, 705, 709

[Modern pharmacotherapy in psychiatry] Vinař O. **Psychiatr Neurol Med Psychol Beih** 1966;4-5:155-71 **(Ger)**

[Chemotherapy and psychotherapy--therapeutic approaches in psychiatric diseases resistant to treatment] Nishizono M. **Seishin Shinkeigaku Zasshi** 1984;86(12):939-50 **(Jpn)**

[Has psychopharmacotherapy had any effect on the chronicity of mental patients? (apropos of the article by A.B. Smulevich and G.P. Panteleev) (letter)] Krasik ED, et al. **Zh Nevropatol Psikhiatr** 1985;85(7):1077-9 **(Rus)**

[Level of dopamine in structures of the nigro-striatal and mesolimbic systems of the brain in experimental pathology of higher nervous activity in the rat] Saul'skaia NB. **Zh Vyssh Nerv Deiat** 1985 May-Jun; 35(3):561-4 (Eng. Abstr.) **(Rus)**

MENTAL PROCESSES

Early visual information processing in depressive patients treated with ORG 2766 (an ACTH 4-9 analogue). d'Elia G, et al. **Neuropsychobiology** 1985;13(1-2):63-8

Effect of neuroleptic treatments on attention, information processing, and thought disorder. Spohn HE, et al. **Psychopharmacol Bull** 1985; 21(3):582-7

The effect of methylphenidate on information processing. Naylor H, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):90-5

MEPROBAMATE

Determination of meprobamate as an n-butylboronate ester derivative in serum by gas-liquid chromatography. Johansson B, et al. **J Chromatogr** 1985 Jun 14;341(2):462-4

METHOTRIMEPRAZINE

[Malignant hyperthermia caused by neuroleptics] Escolano Villén F, et al. **Rev Esp Anestesiol Reanim** 1985 Jul-Aug;32(4):189-91 (Eng. Abstr.) **(Spa)**

METHYLPHENIDATE

Methylphenidate and children with attention deficit disorder. Dose effects on classroom academic and social behavior. Pelham WE, et al. **Arch Gen Psychiatry** 1985 Oct;42(10):948-52

Attention deficit disorder children with or without hyperactivity. Which behaviors are helped by stimulants? Ullmann RK, et al. **Clin Pediatr (Phila)** 1985 Oct;24(10):547-51

Developmental changes in the mother-child interactions of hyperactive boys: effects of two dose levels of Ritalin. Barkley RA, et al. **J Child Psychol Psychiatry** 1985 Sep;26(5):705-15

[3H]Threo-(+/-)-methylphenidate binding to 3,4-dihydroxyphenylethylamine uptake sites in corpus striatum: correlation with the stimulant properties of ritalinic acid esters. Schweri MM, et al. **J Neurochem** 1985 Oct;45(4):1062-70

Methylphenidate (Ritalin) treatment of cocaine dependence--a preliminary report. Khantzian EJ, et al. **J Subst Abuse Treat** 1984;

1(2):107-12

Ten years of experience with 1,000 hyperactive children in a private practice. Eichlseder W. **Pediatrics** 1985 Aug;76(2):176-84

Rate-dependency and hyperactivity: methylphenidate effects on operant responding. Rapport MD, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):77-83

The effect of methylphenidate on information processing. Naylor H, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):90-5

MOTIVATION

Schizophrenia: an amotivational syndrome in men. Lewine R. **Can J Psychiatry** 1985 Aug;30(5):316-8 (17 ref.)

MOTOR ACTIVITY

Side effects of drugs stimulating prolactin secretion on the behavior of male rats. Drago F, et al. **Arch Int Pharmacodyn Ther** 1985 Aug; 276(2):271-8

Differential effects of intrafrontocortical microinjections of dopamine agonists and antagonists on circling behavior of rats. Stewart RJ, et al. **Behav Brain Res** 1985 Sep;17(1):67-72

Increased total activity in the rat after L-tryptophan plus the monoamine oxidase-A inhibitor amiflamine but not after L-tryptophan plus clorgyline. Archer T, et al. **Br J Pharmacol** 1985 Jul;85(3):581-90

The effect of water-deprivation on locomotor activity in rats treated with 6-hydroxydopamine. Seiden LS, et al. **Brain Res** 1985 Jul 1; 337(2):225-32

Behavioural effects in the rat after acute unilateral intranigral infusions of N-methyl-4-phenyl-1,2,3,6-tetrahydropyridine. Sirinathsinghji DJ. **Brain Res** 1985 Jul 29;339(2):366-70

Involvement of amygdaloid catecholaminergic mechanism in suppressive effects of desipramine and imipramine on duration of immobility in rats forced to swim. Araki H, et al. **Eur J Pharmacol** 1985 Jul 31; 113(3):313-8

Neuronal mechanisms involved in drug-induced jumping behavior in mice. Ushijima I, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):225-9

Repeated treatment with imipramine or amitriptyline increases the locomotor response of rats to (+)-amphetamine given into the nucleus accumbens. Maj J, et al. **J Pharm Pharmacol** 1985 May;37(5):362-4

Dopamine agonist-induced locomotor activity in rats treated with 6-hydroxydopamine at differing ages: functional supersensitivity of D-1 dopamine receptors in neonatally lesioned rats. Breese GR, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):447-55

Hyperactivity induced by stimulation of separate dopamine D-1 and D-2 receptors in rats with bilateral 6-OHDA lesions. Arnt J. **Life Sci** 1985 Aug 26;37(8):717-23

Brain NADH and jumping behavior in the rat. Shen Z, et al. **Life Sci** 1985 Aug 26;37(8):731-8

Unilateral lesion of the intrinsic cells in the medial forebrain bundle depresses self-stimulation but not stimulus-bound locomotor activity. Velley L. **Neurosci Lett** 1985 Jun 12;57(2):199-204

Central nervous system effect of 2,5-hexane diol. Agrawal AK, et al. **Neurotoxicology** 1985 Fall;6(3):53-9

The effects of MIF-I, beta-endorphin and alpha-MSH on d-amphetamine induced paradoxical behavioral thermoregulation: possible involvement of the dopaminergic system. Yehuda S, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):189-92

Behavioral responses of high and low active male rats to the chronic ingestion of desipramine. Echandia EL, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):917-20

Effect of DL-erythro-dihydroxyphenylserine on the locomotor activity of the mouse. Mori T, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):979-83

Neonatal 6-hydroxydopamine potentiates clonidine's locomotor effects throughout maturation in the rat. Smythe JW, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):1075-8

Dopamine agonist action in mesolimbic, cortical and extrapyramidal areas to modify spontaneous climbing behaviour of the mouse. Costall B, et al. **Psychopharmacology (Berlin)** 1985;86(4):452-7

Effects of d,l-propranolol on open field behavior of rats. Poli A, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):153-5

Repeated treatment with imipramine potentiates the locomotor effect of apomorphine administered into the hippocampus in rats. Smialowski A, et al. **Psychopharmacology (Berlin)** 1985;86(4):468-71

The comparative long-term effects of ciladopa (AY-27,110), a chemically novel dopaminergic agonist, in 6-OHDA-lesioned and intact rats. Voith K. **Psychopharmacology (Berlin)** 1985;85(4):405-9

Comparison between locomotor activity changes produced by phencyclidine and D-amphetamine in CD-1 male mice. Stavchansky S, et al. **Res Commun Chem Pathol Pharmacol** 1985 May; 48(2):189-202

[Effect of l-stepholidine on rotational behavior in rats] Shi WX, et al. **Chung Kuo Yao Li Hsueh Pao** 1984 Dec;5(4):222-5 (Eng. Abstr.) **(Chi)**

[A simply designed apparatus and its use for measuring vertical and horizontal motor activities in methamphetamine-treated mice] Itoh T, et al. **Yakubutsu Seishin Kodo** 1985 May;5(1):19-23 (Eng. Abstr.) **(Jpn)**

MOTOR SKILLS

Temazepam and the perceptual-motor performance of professional footballers. Golby J, et al. **Br J Sports Med** 1985 Jun;19(2):115-8

MSH

Cell types of the pars distalis of the hedgehog (Erinaceus europaeus L.) adenohypophysis: cytological, immunocytochemical and ultrastructural studies. 3. Opiocorticomelanotropic cells. Girod C, et al. **Acta Anat (Basel)** 1985;123(1):67-71

Dynorphin-A(1-8) and gamma-melanotropin exist within different myenteric plexus neurons of rat duodenum. Wolter HJ. **Biochem Biophys Res Commun** 1985 Sep 16;131(2):821-6

Stress-induced elevation of plasma alpha-MSH and endorphin in brown trout, Salmo trutta L. Sumpter JP, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):257-65

Presence of immunoreactive alpha-melanotropin and beta-endorphin in spinal motoneurones of the dystrophic mouse. Haynes LW, et al. **Neurosci Lett** 1985 Jul 4;58(1):13-8

The effects of MIF-I, beta-endorphin and alpha-MSH on d-amphetamine induced paradoxical behavioral thermoregulation: possible involvement of the dopaminergic system. Yehuda S, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):189-92

Current concepts in premenstrual syndrome. Ullman LE. **RI Med J** 1985 Jun;68(6):269-72

NEUROREGULATORS

Dose-related effects of cysteamine treatment on hypothalamic and striatal dopamine, noradrenaline and serotonin neurotransmission. Vécsei L, et al. **Acta Physiol Hung** 1985;66(2):213-7

Immunocytochemical studies of somatostatin neurons in brain. Elde R, et al. **Adv Exp Med Biol** 1985;188:167-81

Monoamines and the effect of ethanol on corticosterone and non-esterified fatty acids. Brick J, et al. **Alcohol** 1985 Mar-Apr;2(2):261-5

Proctolin induces rhythmic contractions and spikes in Limulus heart muscle. Watson WH 3d, et al. **Am J Physiol** 1985 Oct; 249(4 Pt 2):R490-5

Overview: toward a dysregulation hypothesis of depression. Siever LJ, et al. **Am J Psychiatry** 1985 Sep;142(9):1017-31 (134 ref.)

Distribution of cholecystokinin-like immunoreactivity in the nervous system. Co-existence with classical neurotransmitters and other neuropeptides. Hökfelt T, et al. **Ann NY Acad Sci** 1985;448:255-74

Developmental study on the regulation of neurotransmitter-sensitive adenylate cyclase systems in primary cerebral cell cultures from embryonic mice. Shanker G, et al. **Biosci Rep** 1985 Jul;5(7):601-8

Neurotransmitter-related markers in the normal and experimentally lesioned telencephalon of the goldfish. Bissoli R, et al. **Brain Res** 1985 Oct 7;344(2):397-401

An antiserum to locust adipokinetic hormone reveals a novel peptidergic system in the rat central nervous system. Sasek CA, et al. **Brain Res** 1985 Sep 16;343(1):172-5

Monoamine, amino acid and cholinergic interactions in slices of rat cerebral cortex. Flint RS, et al. **Brain Res Bull** 1985 Aug; 15(2):197-202

Integrative peptides. Hoebel BG. **Brain Res Bull** 1985 Jun;14(6):525-8 (54 ref.)

Peptides as central regulators of feeding. Morley JE, et al. **Brain Res Bull** 1985 Jun;14(6):511-9 (108 ref.)

Measurements of transmitter action: the problem of voltage dependence. MacDonald JF. **Can J Physiol Pharmacol** 1985 Jul;63(7):825-30

Non-vascular central nervous system effects of calcium entry blockers. Govoni S, et al. **Cephalalgia** 1985 May;5 Suppl 2:115-8

Calmodulin, synchronous and asynchronous release of neurotransmitter. Publicover SJ. **Comp Biochem Physiol [A]** 1985;82(1):7-11 (45 ref.)

Distribution and localization of regulatory peptides. Ballesta J, et al. **CRC Crit Rev Clin Lab Sci** 1985;22(3):185-218 (250 ref.)

Inhibition of quantal transmitter release by the polycationic ligand cationized ferritin. Publicover SJ. **Exp Brain Res** 1985;59(3):629-32

Genes for neurotransmitter synthesis, storage, and uptake. Joh TH, et al. **Fed Proc** 1985 Sep;44(12):2773-9

The hyperglycemic factor of the CNS of the freshwater snail Lymnaea stagnalis: interaction with glucose stimulation of glycogen synthesis and evidence for its release during anaerobiosis. Hemminga MA, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):301-7

Circadian variations of neurotransmitter binding in three age groups of rats. Jenni-Eiermann S, et al. **Gerontology** 1985;31(3):138-49

Biochemical and immunochemical approaches to the study of the auditory system. Wenthold RJ. **J Acoust Soc Am** 1985 Jul;78(1 Pt 2):334-9

Depression and serotonin metabolism: rationale for neurotransmitter precursor treatment. Byerley WF, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):191-206 (188 ref.)

In vitro differentiation of neuronal precursor cells from amphibian late gastrulae; morphological, immunocytochemical studies, biosynthesis, accumulation and uptake of neurotransmitters. Duprat AM, et al. **J Embryol Exp Morphol** 1985 Apr;86:71–87

Binding of lanthanum ions and ruthenium red to synaptosomes and its effects on neurotransmitter release. Tapia R, et al. **J Neurochem** 1985 Nov;45(5):1464–70

A genetically controlled hippocampal transmitter system regulating exploratory behavior in mice. van Abeelen JH, et al. **J Neurogenet** 1984 Apr;1(2):153–8

Actions of neurotransmitters on pontine medical reticular formation neurons of the cat. Greene RW, et al. **J Neurophysiol** 1985 Sep; 54(3):520–31

Modulation of neurotransmitter action: control of the gamma–aminobutyric acid response through the benzodiazepine receptor. Chan CY, et al. **J Neurosci** 1985 Sep;5(9):2365–73

Properties of choroid and ciliary neurons in the avian ciliary ganglion and evidence for substance P as a neurotransmitter. Dryer SE, et al. **J Neurosci** 1985 Oct;5(10):2654–61

Effects of changes in motor unit size on transmitter release at the frog neuromuscular junction. Herrera AA, et al. **J Neurosci** 1985 Jul; 5(7):1896–900

Excitatory effect of amino acids on identified neuron R14 of Aplysia. II. Neutral amino acids and structure–activity relationships. Ichinose M, et al. **J Neurosci Res** 1985;14(1):145–58

Evidence against VIP or substance P being the transmitter in non–cholinergic excitatory nerves supplying the guinea–pig bladder. Meldrum LA, et al. **J Pharm Pharmacol** 1985 Jun;37(6):432–4

Effects of K+–channel blockers on transmitter release in bullfrog sympathetic ganglia. Kumamoto E, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):241–7

Non–uniform effects of neurohumoral agents on the internal diameter in parallel and series arranged small arteries in rabbit hindlimb. Sada K, et al. **Jpn J Physiol** 1985;35(2):321–34

Effects of advancing age on hypothalamic neurotransmitter content and on basal and norepinephrine–stimulated LHRH release. Steger RW, et al. **Neurobiol Aging** 1985 Summer;6(2):113–6

Preoptic catecholamine, GABA, and glutamate release in ovariectomized and ovariectomized estrogen–primed rats utilizing a push–pull cannula technique. Demling J, et al. **Neuroendocrinology** 1985 Sep; 41(3):212–8

Effect of chronic lithium administration on neurotransmitter metabolism in synaptosomes from rat brain. Rafałowska U, et al. **Neuropatol Pol** 1985;23(2):211–8

Models for transmitter activation process in retinal rod outer segments to flash stimuli. Ichikawa K. **Neurosci Res** 1985 Jun;2(5):349–64

Neurotransmitters of the hypothalamic suprachiasmatic nucleus: immunocytochemical analysis of 25 neuronal antigens. van den Pol AN, et al. **Neuroscience** 1985 Aug;15(4):1049–86

Ginseng saponins: influence on neurotransmitter uptake in rat brain synaptosomes. Tsang D, et al. **Planta Med** 1985 Jun;(3):221–4

Brain neurotransmitters and appetite regulation. Leibowitz SF. **Psychopharmacol Bull** 1985;21(3):412–8

Peripheral models for the study of neurotransmitter receptors in man. Stahl SM. **Psychopharmacol Bull** 1985;21(3):663–71

[Localization of biogenic monoamines in the dura mater of the rat brain] Motavkin PA, et al. **Arkh Anat Gistol Embriol** 1985 May;88(5):11–6 (Eng. Abstr.) **(Rus)**

[Effect of fenibut on the GABA B receptors of the spinal motor neurons] Abramets II, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):698–700 (Eng. Abstr.) **(Rus)**

[Age aspects of receptor–effector reactions and the regulation of adenylate cyclase activity] Burchinskii SG, et al. **Ukr Biokhim Zh** 1985 Jul–Aug; 57(4):86–98 (101 ref.) (Eng. Abstr.) **(Rus)**

[Analysis of the significance of irregular spike activity in response to mediator action on Helix pomatia neurons] Vagin IuE, et al. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):322–9 (Eng. Abstr.) **(Rus)**

[Conformation study, using an empirical atom–atom potential, of biologically active amino acids as neurotransmitters] Jáuregui EA, et al. **Acta Cient Venez** 1984;35(5–6):337–41 (Eng. Abstr.) **(Spa)**

[Correlation between clinical and laboratory data in depression. Therapeutic orientation by means of vitamins and amino acids] Mesones HL, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):25–36 (Eng. Abstr.) **(Spa)**

NEUROTENSIN

Pharmacological analysis of the mechanism of action for colonic contraction induced by neurotensin, substance P and methionine–enkephalin. Hellström PM. **Acta Physiol Scand** 1985 Sep; 125(1):13–24

Neurotensin–like immunoreactivity in some preparations of secretin and cholecystokinin. Feurle GE. **Agents Actions** 1985 Jul;16(5):411–4

Structure–activity studies with carboxy– and amino–terminal fragments of neurotensin on hypothalamic neurons in vitro. Baldino F Jr, et al. **Brain Res** 1985 Sep 9;342(2):266–72

The comparative distribution of [Lys8–Asn9]–neurotensin8–13–like immunoreactivity in chicken and rat tissues. Goedert M, et al. **Brain Res** 1985 Sep 9;342(2):259–65

Neurotensin depolarizes substantia nigra dopamine neurones. Pinnock RD. **Brain Res** 1985 Jul 8;338(1):151–4

Phylogenetic conservatism in the presence of a neurotensin–related hexapeptide in neurons of globus pallidus. Reiner A, et al. **Brain Res** 1985 Aug 26;341(2):365–71

Effect of vagal blockade on food– and hormone–stimulated release of pancreatic polypeptide and motilin in dogs. Greenberg GR, et al. **Dig Dis Sci** 1985 Oct;30(10):946–53

Effect of truncal vagotomy on neurotensin–like immunoreactivity release in dogs. Yoshiya K, et al. **Gastroenterol Jpn** 1985 Jun;20(3):197–200

Inactivation of neurotensin by rat brain synaptic membranes partly occurs through cleavage at the Arg8–Arg9 peptide bond by a metalloendopeptidase. Checler F, et al. **J Neurochem** 1985 Nov; 45(5):1509–13

The application of enzyme–linked immunosorbent assays (ELISA) to neuropeptides. Davis LG, et al. **J Neurosci Methods** 1985 Jun; 14(1):15–23

Effects of intraventricular neurotensin on blood pressure and heat balance in rats. Shido O, et al. **Jpn J Physiol** 1985;35(2):311–20

Neurotensin stimulates polyphosphoinositide breakdown and prolactin release in anterior pituitary cells in culture. Canonico PL, et al. **Mol Cell Endocrinol** 1985 Oct;42(3):215–20

Primary explants as a model of the hypothalamus in situ. Baldino F Jr, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):249–56

Distribution of neurotensin–like immunoreactivity in rat and cat area postrema. Newton BW, et al. **Peptides (Fayetteville)** 1985 Mar–Apr; 6(2):301–6

Emetic effects of centrally administered angiotensin II, arginine vasopressin and neurotensin in the dog. Wu M, et al. **Peptides (Fayetteville)** 1985;6 Suppl 1:173–5

Importance of the ileum in neurotensin released by fat. Walker JP, et al. **Surgery** 1985 Aug;98(2):224–9

NEUROTIC DISORDERS

Chronic treatments in neuropsychiatry. **Adv Biochem Psychopharmacol** 1985;40:1–219

[Psychoneurotic disorders in puberty and the activity of the adrenergic system] Szewczyk L. **Pediatr Pol** 1985 Apr;60(4):306–11 (Eng. Abstr.) **(Pol)**

[Selected elements of complex therapy in the opinion of former patients of the neurosis ward of the Psychiatric Clinic in Bydgoszcz] Brzeziński R. **Psychiatr Pol** 1984 Sep–Oct;18(5):457–63 (Eng. Abstr.) **(Pol)**

[Effect of insulin and its polymeric analogs on learning and memory processes in the rabbit] Bakharev VD, et al. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):314–21 (Eng. Abstr.) **(Rus)**

NITRAZEPAM

Determination of nitrazepam and its main metabolites in urine by thin–layer chromatography and direct densitometry. Inoue T, et al. **J Chromatogr** 1985 Apr 12;339(1):163–9

NOMIFENSINE

Depression and anxiety: mianserin and nomifensine compared in a double–blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67–74

Mianserin is better tolerated and more effective in depression than a nomifensine–clobazam combination: a double–blind study. Levin A, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:75–80

Fatal immune haemolysis associated with nomifensine [letter] Ross JR. **Br Med J [Clin Res]** 1985 Aug 31;291(6495):606

Suppression of MPTP–induced dopaminergic neurotoxicity in mice by nomifensine and L–DOPA. Melamed E, et al. **Brain Res** 1985 Sep 9; 342(2):401–4

Psychopharmacological effects of nomifensine enantiomers. Poncelet M, et al. **Eur J Pharmacol** 1985 Jul 17;113(2):271–4

NOREPINEPHRINE

Beta receptors in peripheral mononuclear cells increase acutely during exercise. Burman KD, et al. **Acta Endocrinol (Copenh)** 1985 Aug; 109(4):563–8

The vasopressin response to microinjections of norepinephrine into the brain of the conscious pig. Forsling ML, et al. **Acta Endocrinol (Copenh)** 1985 Jul;109(3):330–4

Relationship between the release and uptake of noradrenaline by rat brain synaptosomes in the formation of defensive conditioned reflex. Bazyan AS, et al. **Acta Neurobiol Exp (Warsz)** 1985;45(1–2):37–46

Influence of beta–receptor stimulation on catecholamine and phospholipid concentrations in lungs of fetal rabbits. Urban J, et al. **Acta Paediatr Hung** 1985;26(2):127–32

Effect of the rate of blood loss on the plasma catecholamine response. Tárnoky K, et al. **Acta Physiol Hung** 1985;66(2):143–53

Subcellular storage and axonal transport of neuropeptide Y (NPY) in relation to catecholamines in the cat. Fried G, et al. **Acta Physiol Scand** 1985 Sep;125(1):145–54

The relation between in vitro efflux of noradrenaline from platelets and vas deferens in man. Mattiasson I, et al. **Acta Physiol Scand** 1985 Sep;125(1):155–8

Indirect adrenergic effect of compound 48/80 in cat cerebral arteries. Marco EJ, et al. **Agents Actions** 1985 Jul;16(5):310–2

Systemic and uterine responsiveness to angiotensin II and norepinephrine in estrogen-treated nonpregnant sheep. Naden RP, et al. **Am J Obstet Gynecol** 1985 Oct 15;153(4):417–25

Effect of norepinephrine on gluconeogenesis in perfused livers of cold-exposed rats. Shiota M, et al. **Am J Physiol** 1985 Sep;249(3 Pt 1):E281–6

Diurnal-stimulated and stress-induced ACTH release in rats is mediated by ventral noradrenergic bundle. Szafarczyk A, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):E219–26

Spermatogenesis of rat: effect of central norepinephrine synthesis inhibition by diethyldithiocarbamate. Mazumder R, et al. **Andrologia** 1985 Jul–Aug;17(4):400–5

Effect of norepinephrine and vasopressin on renal kallikrein excretion in rats. Martinez Seeber A, et al. **Arch Int Physiol Biochim** 1985 Jun;93(2):83–8

Change of catecholamine turnover in ovary during the rat estrous cycle. Nagahara Y, et al. **Asia Oceania J Obstet Gynaecol** 1985 Jun;11(2):261–4

Stress, catecholamines, and sleep. Harrison GA. **Aviat Space Environ Med** 1985 Jul;56(7):651–3

Evidence that noradrenaline increases pyruvate dehydrogenase activity and decreases acetyl-CoA carboxylase activity in rat interscapular brown adipose tissue in vivo. Gibbins JM, et al. **Biochem J** 1985 Jun 15;228(3):751–5

Alpha-adrenergic stimulation of glutamine metabolism in isolated rat hepatocytes. Verhoeven AJ, et al. **Biochem J** 1985 Sep 1;230(2):457–63

Metabolism of carbidopa to alpha-methyldopamine and alpha-methylnorepinephrine in rats. Shelton RC, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3623–6

Control of oxygen uptake, microcirculation and glucose release by circulating noradrenaline in perfused rat liver. Beckh K, et al. **Biol Chem Hoppe Seyler** 1985 Jul;366(7):671–8

Plasma melatonin during desmethylimipramine treatment: evidence for changes in noradrenergic transmission. Cowen PJ, et al. **Br J Clin Pharmacol** 1985 Jun;19(6):799–805

Comparison of the antagonistic effects of phentolamine on vasoconstrictor responses to exogenous and neurally released noradrenaline in vivo. Bell C. **Br J Pharmacol** 1985 May;85(1):249–53

Effect of the dihydropyridine Bay K 8644 on the release of [3H]-noradrenaline from the rat isolated vas deferens. Ceña V, et al. **Br J Pharmacol** 1985 Jul;85(3):691–6

Bay K 8644, a dihydropyridine calcium agonist, augments vasoconstrictor responses to endogenous and exogenous noradrenaline in the peripheral vasculature of the dog. Goto T, et al. **Br J Pharmacol** 1985 Aug;85(4):913–6

The effect of diltiazem on noradrenaline release. Wolchinsky C, et al. **Br J Pharmacol** 1985 Jun;85(2):387–93

Coexistence of vasopressin, neurophysin and noradrenaline immunoreactivity in medium-sized cells of the locus coeruleus and subcoeruleus in the rat. Caffé AR, et al. **Brain Res** 1985 Jul 8;338(1):160–4

Amygdala norepinephrine involved in two separate long-term memory retrieval processes. Ellis ME. **Brain Res** 1985 Sep 2;342(1):191–5

Desensitization of beta-receptors on primary astrocyte cultures by norepinephrine but not by tricyclic antidepressants. Frangakis MV, et al. **Brain Res** 1985 Jul 22;339(1):49–56

Regional depletion of central nervous system catecholamines: effects on blood pressure and drinking behavior. Gordon FJ, et al. **Brain Res** 1985 Oct 21;345(2):285–97

Water deprivation increases anterior hypothalamic norepinephrine metabolism in the rat. Klemfuss H, et al. **Brain Res** 1985 Aug 26;341(2):222–7

Exogenous monoamines affect the segregation of retinogeniculate fibers in developing rats. Land PW, et al. **Brain Res** 1985 Sep;354(1):135–40

Growth cones isolated from developing rat forebrain: uptake and release of GABA and noradrenaline. Lockerbie RO, et al. **Brain Res** 1985 Aug;353(2):265–75

Effects of norepinephrine on rat neocortical neurons in dissociated cell culture. Rosenberg PA, et al. **Brain Res** 1985 Oct 7;344(2):369–72

Amphetamine's effects on terminal excitability of noradrenergic locus coeruleus neurons are impulse-dependent at low but not high doses. Ryan LJ, et al. **Brain Res** 1985 Aug 19;341(1):155–63

In vivo modulation of norepinephrine-induced cerebral oxygenation states by hypoxia and hyperoxia. Sylvia AL, et al. **Brain Res** 1985 Jul 15;338(2):281–8

Norepinephrine stimulates serotonin secretion from rat pineal glands, in vitro. Walker RF, et al. **Brain Res** 1985 Sep 16;343(1):188–9

Neonatal monosodium glutamate administration alters noradrenergic measures in the brainstem of the mouse. Dawson R Jr, et al. **Brain Res Bull** 1985 Aug;15(2):117–21

Monoamine transmitter release induced by tetrahydro-beta-carboline perfused in hippocampus of the unrestrained rat. Huttunen P, et al. **Brain Res Bull** 1985 Aug;15(2):215–20

Action of serotonin and norepinephrine on spinal motoneurones following blockade of synaptic transmission. Neuman RS. **Can J Physiol Pharmacol** 1985 Jun;63(6):735–8

Neuronally released norepinephrine does not preferentially activate postjunctional alpha 1-adrenoceptors in human blood vessels in vitro. Stevens MJ, et al. **Circ Res** 1985 Sep;57(3):399–405

Increased sensitivity of rabbit ear artery to noradrenaline following perivascular nerve stimulation may be a response to neuropeptide Y released as cotransmitter. Glover WE. **Clin Exp Pharmacol Physiol** 1985 May–Jun;12(3):227–30

Increased plasma noradrenaline during low dose adrenaline infusion in resting man and during sympathetic stimulation. Musgrave IF, et al. **Clin Exp Pharmacol Physiol** 1985 May–Jun;12(3):285–9

Beta-adrenoceptor responsiveness and plasma catecholamines as determinants of cardiovascular reactivity to mental stress. Eisenhofer G, et al. **Clin Sci** 1985 Oct;69(4):483–92

Effect of gonadectomy on brain catecholamines during the postnatal period. Leret ML, et al. **Comp Biochem Physiol [C]** 1985;81(2):405–9

Adrenergic stimulation of adrenocortical secretion in immature fowl. Rees A, et al. **Comp Biochem Physiol [C]** 1985;81(2):387–9

Effect of norepinephrine on ketogenesis, fatty acid oxidation, and esterification in isolated rat hepatocytes. Oberhaensli RD, et al. **Diabetes** 1985 Aug;34(8):774–9

Effect of microelectrophoretically applied acetylcholine, noradrenaline, dopamine and serotonin on the discharge of paraventricular oxytocinergic neurones in the rat. Honda K, et al. **Endocrinol Jpn** 1985 Feb;32(1):127–33

Elevated catecholamines in porcine follicular fluid before ovulation. Bahr JM, et al. **Endocrinology** 1985 Aug;117(2):620–3

Examination of the effects of epinephrine, norepinephrine, and dopamine on aldosterone production in bovine glomerulosa cells in vitro. Sequeira SJ, et al. **Endocrinology** 1985 Nov;117(5):1947–52

Rapid bidirectional effects of insulin on hypothalamic noradrenergic and serotoninergic neuronal activity in the rat: role in glucose homeostasis. Smythe GA, et al. **Endocrinology** 1985 Oct;117(4):1590–7

Plasma testosterone and catecholamine responses to physical exercise of different intensities in men. Ježová D, et al. **Eur J Appl Physiol** 1985;54(1):62–6

Postsynaptic alpha 2-noradrenergic receptors mediate feeding induced by paraventricular nucleus injection of norepinephrine and clonidine. Goldman CK, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):11–9

Trimipramine, a tricyclic antidepressant exerting atypical actions on the central noradrenergic system. Hauser K, et al. **Eur J Pharmacol** 1985 Apr 23;111(1):23–30

Chronic clonidine induces functional down-regulation of presynaptic alpha 2-adrenoceptors regulating [3H]noradrenaline and [3H]5-hydroxytryptamine release in the rat brain. Maura G, et al. **Eur J Pharmacol** 1985 May 28;112(1):105–10

Action of norepinephrine in the dentate gyrus. I. Stimulation of locus coeruleus. Dahl D, et al. **Exp Brain Res** 1985;59(3):491–6

Substantial reduction of noradrenaline in kitten visual cortex by intraventricular injections of 6-hydroxydopamine does not always prevent ocular dominance shifts after monocular deprivation. Daw NW, et al. **Exp Brain Res** 1985;59(1):30–5

Sex-specific effects of estradiol on hypothalamic noradrenaline turnover in gonadectomized rats. Hiemke C, et al. **Exp Brain Res** 1985;59(1):68–72

Action of norepinephrine in the dentate gyrus. II. Iontophoretic studies. Winson J, et al. **Exp Brain Res** 1985;59(3):497–506

Diet and weight loss: their effect on norepinephrine renin and aldosterone levels. Grossman E, et al. **Int J Obes** 1985;9(2):107–14

Vascular responses to intravenous catecholamines in hands and forearms with normal and with increased skin blood flow. Allen JA, et al. **Ir J Med Sci** 1985 May;154(5):178–86

The hemodynamic and plasma catecholamine responses to routine restorative dental care. Cioffi GA, et al. **J Am Dent Assoc** 1985 Jul;111(1):67–70

Reserpic acid as an inhibitor of norepinephrine transport into chromaffin vesicle ghosts. Chaplin L, et al. **J Biol Chem** 1985 Sep 15;260(20):10981–5

Association of the changes in cytosolic Ca2+ and iodide efflux induced by thyrotropin and by the stimulation of alpha 1-adrenergic receptors in cultured rat thyroid cells. Corda D, et al. **J Biol Chem** 1985 Aug 5;260(16):9230–6

Catecholamine and vasopressin stimulation of gluconeogenesis from dihydroxyacetone in the presence of atractyloside. Warnette-Hammond

ME, et al. **J Biol Chem** 1985 Oct 15;260(23):12647–52

In vitro studies on responses to noradrenaline, serotonin, and potassium of intramyocardial and mesenteric resistance vessels from Wistar rats. Nyborg NC, et al. **J Cardiovasc Pharmacol** 1985 May-Jun; 7(3):417–23

Norepinephrine and epidermal growth factor: dynamics of their interaction in the stimulation of hepatocyte DNA synthesis. Cruise JL, et al. **J Cell Physiol** 1985 Oct;125(1):45–50

Determination of adult sheep plasma catecholamines using [3H]norepinephrine as the internal standard. Boylan JM, et al. **J Chromatogr** 1985 Feb 27;338(1):192–4

Haemodynamic and catecholamine responses to hypothermia in the fetal sheep in utero. Gunn TR, et al. **J Dev Physiol** 1985 Aug;7(4):241–9

Antioestrogen inhibition of oestradiol-induced alterations in hypothalamic noradrenaline turnover. Hiemke C, et al. **J Endocrinol** 1985 Jul; 106(1):37–42

Time-dependent effects of oestradiol and progesterone on hypothalamic catecholamine turnover in ovariectomized rats. Hiemke C, et al. **J Endocrinol** 1985 Sep;106(3):303–9

Differential coupling of GABA-A and GABA-B receptors to the noradrenergic system. Suzdak PD, et al. **J Neural Transm** 1985; 62(1-2):77–89

Cholinergic- and adrenergic-stimulated inositide hydrolysis in brain: interaction, regional distribution, and coupling mechanisms. Gonzales RA, et al. **J Neurochem** 1985 Oct;45(4):1076–84

Norepinephrine turnover in the hypothalamus of adult male rats: alteration of circadian patterns by semistarvation. Schweiger U, et al. **J Neurochem** 1985 Sep;45(3):706–9

Alteration in the postnatal ontogeny of cerebellar norepinephrine content following chronic prenatal carbon monoxide. Storm JE, et al. **J Neurochem** 1985 Sep;45(3):965–9

DSP-4 (N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine) depletes noradrenaline in kitten visual cortex without altering the effects of monocular deprivation. Daw NW, et al. **J Neurosci** 1985 Jul; 5(7):1925–33

Depletion of norepinephrine, but not serotonin, reduces long-term potentiation in the dentate gyrus of rat hippocampal slices. Stanton PK, et al. **J Neurosci** 1985 Aug;5(8):2169–76

Ouabain-evoked norepinephrine release from intact rat sympathetic neurons: evidence for carrier-mediated release. Sweadner KJ. **J Neurosci** 1985 Sep;5(9):2397–406

Effect of uptake-one inhibitors on the uptake of norepinephrine and metaiodobenzylguanidine. Tobes MC, et al. **J Nucl Med** 1985 Aug; 26(8):897–907

Energy intake, norepinephrine excretion, and oxygen consumption in low birthweight infants. Weinstein MR, et al. **J Pediatr Gastroenterol Nutr** 1985 Oct;4(5):774–7

Hypernoradrenergic innervation of the caudal artery of the spontaneously hypertensive rat: an influence upon neuroeffector mechanisms. Cassis LA, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):792–803

Effect of imipramine and adrenocorticotropin administration on the rat brain norepinephrine-coupled cyclic nucleotide generating system: alterations in alpha and beta adrenergic components. Duman RS, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):409–14

Neuropeptide Y potentiates noradrenaline-evoked vasoconstriction: mode of action. Wahlestedt C, et al. **J Pharmacol Exp Ther** 1985 Sep; 234(3):735–41

Non-uniform effects of neurohumoral agents on the internal diameter in parallel and series arranged small arteries in rabbit hindlimb. Sada K, et al. **Jpn J Physiol** 1985;35(2):321–34

Evidence for a role of PTH in the reduced pressor response to norepinephrine in chronic renal failure. Iseki K, et al. **Kidney Int** 1985 Jul;28(1):11–5

Free and conjugated catecholamines in digestive tissues of rats. Gaudin C, et al. **Life Sci** 1985 Oct 21;37(16):1469–74

Plasma dihydroxyphenylglycol (DHPG) in the in vivo assessment of human neuronal norepinephrine metabolism. Izzo JL Jr, et al. **Life Sci** 1985 Sep 16;37(11):1033–8

Differential effects of DSP-4 administration on regional brain norepinephrine turnover in rats. Logue MP, et al. **Life Sci** 1985 Aug 5;37(5):403–9

Dopamine-beta-hydroxylase inhibition acutely stimulates rats hypothalamic noradrenaline and dopamine neuronal activity as assessed from metabolic ratios and circulating glucose and ACTH responses. Smythe GA, et al. **Life Sci** 1985 Sep 2,37(9):841–7

The effect of long-term intraarterial norepinephrine infusion on transcapillary fluid and protein transport. Friedman JJ, et al. **Microvasc Res** 1985 Jul;30(1):45–55

In vivo fluorescence microscopy of blood flow in mouse pancreatic islets: adrenergic effects in lean and obese-hyperglycemic mice. Rooth P, et al. **Microvasc Res** 1985 Sep;30(2):176–84

Role of adenosine 3',5'-cyclic monophosphate in adrenoceptor-mediated control of 3H-noradrenaline secretion in guinea-pig ileum myenteric nerve terminals. Alberts P, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):114–20

Very rapid turnover of dopamine in noradrenaline cell body regions. Andén NE, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 May; 329(3):258–63

Endogenous noradrenaline as modulator of hippocampal serotonin (5-HT)-release. Dual effects of yohimbine, rauwolscine and corynanthine as alpha-adrenoceptor antagonists and 5-HT-receptor agonists. Feuerstein TJ, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 May;329(3):216–21

Dopaminergic modulation of hippocampal noradrenaline release. Evidence for alpha 2-antagonistic effects of some dopamine receptor agonists and antagonists. Jackisch R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):105–13

Cyclic AMP facilitates the electrically evoked release of radiolabelled noradrenaline, dopamine and 5-hydroxytryptamine from rat brain slices. Schoffelmeer AN, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jul;330(1):74–6

Interaction of norepinephrine with Purkinje cell responses to cerebellar afferent inputs in aged rats. Bickford PC, et al. **Neurobiol Aging** 1985 Summer;6(2):89–94

Effects of advancing age on hypothalamic neurotransmitter content and on basal and norepinephrine-stimulated LHRH release. Steger RW, et al. **Neurobiol Aging** 1985 Summer;6(2):113–6

Noradrenergic afferents facilitate the activity of tuberoinfundibular neurons of the hypothalamic paraventricular nucleus. Day TA, et al. **Neuroendocrinology** 1985 Jul;41(1):17–22

Adenosine: an endogenous modulator of hippocampal noradrenaline release. Jackisch R, et al. **Neuropharmacology** 1985 Jun;24(6):499–507

Interaction between the baroreflex and anterior hypothalamic stimulation. Demonstration of a noradrenergic involvement. Simon OR, et al. **Neuropharmacology** 1985 Jul;24(7):665–75

Serotonin and norepinephrine-dependent effects of fenfluramine on plasma renin activity in conscious male rats. Van de Kar LD, et al. **Neuropharmacology** 1985 Jun;24(6):487–94

Brain noradrenergic activity in wakefulness and paradoxical sleep: the effect of clonidine. Gaillard JM. **Neuropsychobiology** 1985; 13(1-2):23–5

Biochemical, physical and psychological findings in patients suffering from cardiac neurosis. Gasic S, et al. **Neuropsychobiology** 1985; 13(1-2):12–6

Neuroendocrine differences between violent and non-violent parasuicides. Prasad AJ. **Neuropsychobiology** 1985;13(4):157–9

Electrical stimulation of the ventral noradrenergic tract (VNAT) releases hypothalamic noradrenaline and stimulates prolactin secretion in ovariectomized female rats treated with oestrogen. Dean AD, et al. **Neurosci Lett** 1985 Jun 4;57(1):73–8

Inactivation by 6-hydroxydopamine of the cerebral factor(s) responsible for the inhibition of the autoxidation of norepinephrine in vitro. Kovachich GB. **Neurosci Lett** 1985 Jul 31;58(2):245–50

Laminar distributions of neurons sensitive to acetylcholine, noradrenaline and dopamine in the dorsolateral prefrontal cortex of the monkey. Sawaguchi T, et al. **Neurosci Res** 1985 Apr;2(4):255–73

Substance P given intrathecally at the spinal T9 level increases adrenal output of adrenaline and noradrenaline in the rat. Yashpal K, et al. **Neuroscience** 1985 Jun;15(2):529–36

Polychlorinated biphenyls induce regional changes in brain norepinephrine concentrations in adult rats. Seegal RF, et al. **Neurotoxicology** 1985 Fall;6(3):13–23

The role of central noradrenergic neurons in electroconvulsive shock-induced muricide inhibition in olfactory bulbectomized rats. Liou SY, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):65–70

Norepinephrine-facilitated eating: reduction in saccharin preference and conditioned flavor preferences with increase in quinine aversion. Matthews JW, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):1045–52

Suppressant effect of REM sleep deprivation on neophobia in normal rats and in rats with selective DSP-4 induced damage of locus coeruleus neurons. Mogilnicka E, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):93–7

Central serotonin neurones in avoidance learning: interactions with noradrenaline and dopamine neurones. Ogren SO. **Pharmacol Biochem Behav** 1985 Jul;23(1):107–23

Differential sensitivity to prazosin and yohimbine blockade of tyramine and noradrenaline. Lucchelli A, et al. **Pharmacol Res Commun** 1985 Aug;17(8):787–801

Noradrenergic modulation of 4-aminopyridine-induced acetylcholine release from rat cerebral cortex. Magnani M, et al. **Pharmacol Res Commun** 1985 Jul;17(7):653–8

Evidence of norepinephrine-mediated suppression of para-chlorophenylalanine-induced muricidal behavior. Pucilowski O, et al. **Pharmacol Res Commun** 1985 May;17(5):457–62

Human class I alcohol dehydrogenases catalyze the oxidation of glycols in the metabolism of norepinephrine. Mårdh G, et al. **Proc Natl Acad Sci USA** 1985 Aug;82(15):4979–82

The effect of etidocaine on spontaneous and evoked release of norepinephrine from rat brain synaptosomes. Freas W, et al. **Proc Soc Exp Biol Med** 1985 Nov;180(2):264–9

The efflux from and the metabolism of 3H-norepinephrine in sow Graafian

follicles. Variable involvement of some prostaglandins during two different stages of the sex cycle. Fernandez-Pardal J, et al. **Prostaglandins Leukotrienes Med** 1985 Jul;19(1):1–10

Adrenergic stimulation modifies prostaglandin synthesis by rat vas deferens. Peredo H, et al. **Prostaglandins Leukotrienes Med** 1985 Jul; 19(1):51–61

Altered norepinephrine metabolism following long-term weight recovery in patients with anorexia nervosa. Kaye WH, et al. **Psychiatry Res** 1985 Apr;14(4):333–42

Serotonergic modulation of cortical rat noradrenergic system in the mechanism of action of antidepressant drugs. Brunello N, et al. **Psychopharmacol Bull** 1985;21(3):379–84

Disturbances of norepinephrine metabolism and alpha-2 adrenergic receptor activity in anorexia nervosa: relationship to nutritional state. Kaye WH, et al. **Psychopharmacol Bull** 1985;21(3):419–23

CSF, plasma, and urine: what do concomitant measurements of norepinephrine and its metabolites mean? Linnoila M, et al. **Psychopharmacol Bull** 1985;21(3):389–95

The serotonin/norepinephrine-linked beta-adrenoceptor system and the mode of action of antidepressants. Sanders-Bush E, et al. **Psychopharmacol Bull** 1985;21(3):373–8

Ro 11-2465 (cyan-imipramine), citalopram and their N-desmethyl metabolites: effects on the uptake of 5-hydroxytryptamine and noradrenaline in vivo and related pharmacological activities. Pawlowski L, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):156–63

Plasma adrenaline and noradrenaline during mental stress and isometric exercise in man. The role of arterial sampling. Jörgensen LS, et al. **Scand J Clin Lab Invest** 1985 Sep;45(5):447–52

The effect of stimulus preexposure upon the context effect in taste-aversion learning in noradrenaline-depleted rats. Archer T. et al. **Scand J Psychol** 1985;26(2):158–69

Relationship between pelviureteral peristaltic frequency and urine flow change evoked by autonomic drug administration. Morita T, et al. **Tohoku J Exp Med** 1985 Jul;146(3):265–71

[Study of the metabolism of cerebral noradrenaline in depressed patients by the assay of plasma dihydroxyphenylethylene glycol] Loo H, et al. **Presse Med** 1985 Jun 22;14(25):1363–6 (Eng. Abstr.) **(Fre)**

[Psychoneurotic disorders in puberty and the activity of the adrenergic system] Szewczyk L. **Pediatr Pol** 1985 Apr;60(4):306–11 (Eng. Abstr.) **(Pol)**

[Effect of leu-enkephalin and the delta-sleep-inducing peptide, M (DSIP), on endogenous noradrenaline release by brain synaptosomes in the rat] Rozhanets VV, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):199–201 (Eng. Abstr.) **(Rus)**

[Effect of Na+, K+ and Ca++ ions on catecholamine release in the caudal mesenteric ganglion] Reprintseva VM. **Fiziol Zh SSSR** 1985 May; 71(5):561–8 (Eng. Abstr.) **(Rus)**

[Action of noradrenaline and dopamine on the pacemaker cells of the normal rat sinus node and in pharmacological sympathectomy] Sutiagin PV, et al. **Kardiologiia** 1985 May;25(5):88–93 (Eng. Abstr.) **(Rus)**

[Changes in the ultrastructure of synapses of neurons of the cerebral cortex of the rat in response to isolated and combined microapplications of mediators] Kotliar BI, et al. **Neirofiziologiia** 1985;17(4):476–81 (Eng. Abstr.) **(Rus)**

[Effect of carbon dioxide baths on the content of catecholamines in the brain and processes of their inactivation] Mirzoian SA, et al. **Vopr Kurortol Fizioter Lech Fiz Kult** 1985 May–Jun;(3):16–9 (Eng. Abstr.) **(Rus)**

[Functional differentiation of the theta-rhythm of the hippocampus in the cat] Melikov EM. **Zh Vyssh Nerv Deiat** 1985 May–Jun; 35(3):457–64 (Eng. Abstr.) **(Rus)**

[Effect of noradrenaline, microapplied to the dorsal hippocampus of the rat, on conditioned reflex memory] Melikov EM, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):780–2 **(Rus)**

[Formation and extinction of drinking conditioned reflexes after unilateral intercollicular sectioning of the brain in the rat] Shabanov PD, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):777–9 **(Rus)**

[Effect of corticosteroid therapy of various durations on urinary excretion of norepinephrine] Ješić S, et al. **Srp Arh Celok Lek** 1984 Nov–Dec; 112(11–12):1135–44 (Eng. Abstr.) **(Scc)**

NORTRIPTYLINE

Separate and combined anxiolytic and anti-depressant treatment of mixed anxiety/depression. A double-blind, placebo controlled comparison. Sussex Clinical Trials Group. **Acta Psychiatr Scand** 1985 Jul; 72(1):81–8

Relationship of free nortriptyline levels to therapeutic response. Perry PJ, et al. **Acta Psychiatr Scand** 1985 Aug;72(2):120–5

Serial ECG measurements at controlled plasma levels of nortriptyline in depressed children. Geller B, et al. **Am J Psychiatry** 1985 Sep; 142(9):1095–7

Nortriptyline in the treatment of a monosymptomatic delusion [letter] Pylko T, et al. **Am J Psychiatry** 1985 Oct;142(10):1223

Plasma concentrations of nortriptyline and its 10-hydroxy metabolite in depressed patients—relationship to the debrisoquine hydroxylation metabolic ratio. Nordin C, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):832–5

Cerebrospinal fluid levels of amitriptyline, nortriptyline, imipramine and desmethylimipramine. Relationship to plasma levels and treatment outcome. Hanin I, et al. **J Affective Disord** 1985 Jul;9(1):69–78

Nortriptyline pharmacokinetics and plasma levels: implications for clinical practice. Rubin EH, et al. **J Clin Psychiatry** 1985 Oct;46(10):418–24 (56 ref.)

Serial monitoring and achievement of steady state nortriptyline plasma levels in depressed children and adolescents: preliminary data. Geller B, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):213–6

[Serum levels of amitriptyline and nortriptyline in a case of poisoning (letter)] Fernández de Gatta M, et al. **Med Clin (Barc)** 1985 May 18; 84(19):798–9 **(Spa)**

OBSESSIVE-COMPULSIVE DISORDER

Antiobsessive effect of fluoxetine [letter] Fontaine R, et al. **Am J Psychiatry** 1985 Aug;142(8):989

Clomipramine treatment of childhood obsessive-compulsive disorder. A double-blind controlled study. Flament MF, et al. **Arch Gen Psychiatry** 1985 Oct;42(10):977–83

Fluoxetine treatment of obsessive-compulsive disorder. Turner SM, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):207–12

ORGANIC MENTAL DISORDERS

Involutional dementias: new perspectives. Borromei A, et al. **Ital J Neurol Sci** 1985 Jun;6(2):167–71

Double-blind, placebo-controlled, clinical, psychometric and neurophysiological investigations with oxiracetam in the organic brain syndrome of late life. Saletu B, et al. **Neuropsychobiology** 1985; 13(1–2):44–52

Effect of neuroleptic treatments on attention, information processing, and thought disorder. Spohn HE, et al. **Psychopharmacol Bull** 1985; 21(3):582–7

ORGANIC MENTAL DISORDERS, PSYCHOTIC

De Clérambault's syndrome—a nosological entity [letter] Munro A. **Br J Psychiatry** 1985 May;146:561

OXAZEPAM

The influence of diflunisal on the pharmacokinetics of oxazepam. van Hecken AM, et al. **Br J Clin Pharmacol** 1985 Sep;20(3):225–34

Inhibition of diazepam metabolism in microsomal- and perfused liver preparations of the rat by desmethyldiazepam, N-methyloxazepam and oxazepam. Savenije-Chapel EM, et al. **Eur J Drug Metab Pharmacokinet** 1985 Jan–Mar;10(1):15–20

PAIRED-ASSOCIATE LEARNING

Psychostimulant plasma concentration and learning performance. Kupietz SS, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):293–5

PARASYMPATHOMIMETICS

Affinity and efficacy correlate with chemical structure more than potency does in a series of pentatomic cyclic muscarinic agonists. Angeli P, et al. **Br J Pharmacol** 1985 Aug;85(4):783–6

Enthalpy-entropy relationship in drug-cholinoceptor interaction: a new approach. Cohen S, et al. **Br J Pharmacol** 1985 Aug;85(4):889–96

Presynaptic actions of cholinergic agents upon the hair cell-afferent fiber synapse in the vestibular labyrinth of the frog. Bernard C, et al. **Brain Res** 1985 Jul 15;338(2):225–36

Effects of cholinergic drugs and 4-aminopyridine on cat ciliary muscle contractility. Zacharias J, et al. **Invest Ophthalmol Vis Sci** 1985 Sep; 26(9):1309–13

Potential types of response of the parasympathetic denervated human parotid gland to cholinergic ligands. Levin SL. **J Auton Nerv Syst** 1985 Jun;13(2):161–70

Muscarinic receptor agonist-antagonist interaction in the rat rectum: are there ways of activating the same receptors? Akah PA, et al. **J Pharm Pharmacol** 1985 Aug;37(8):589–92

Rapid induction of supersensitivity to muscarinic antagonists-induced motor excitation by continuous stimulation of cholinergic receptors. Fernando JC, et al. **Life Sci** 1985 Sep 2;37(9):883–92

Reduced muscarinic receptor plasticity in frontal cortex of aged rats after chronic administration of cholinergic drugs. Pedigo NW Jr, et al. **Life Sci** 1985 Oct 14;37(15):1443–9

Muscarinic depression of evoked surface-negative field potentials recorded from guinea-pig olfactory cortex in vitro. Williams SH, et al. **Neurosci Lett** 1985 May 23;56(3):301–6

Memory enhancement: supra-additive effect of subcutaneous cholinergic drug combinations in mice. Flood JF, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):61–7

[Effect of cholino- and adrenomimetic substances on B-lymphocyte proliferation in mice during a primary immune response to a protein antigen] Ado AD, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):46-8 (Eng. Abstr.) **(Rus)**

PARGYLINE

Epinephrine accumulation in rat brain after chronic administration of pargyline and LY 51641—comparison with other brain amines. Mefford IN, et al. **Brain Res** 1985 Jul 29;339(2):342-5

Trace amines inhibit the electrically evoked release of [3H]acetylcholine from slices of rat striatum in the presence of pargyline: similarities between beta-phenylethylamine and amphetamine. Baud P, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):220-9

Inhibition of tyrosine hydroxylation in rat striatal tissue slices by 1-methyl-4-phenylpyridinium ion. Hirata Y, et al. **Neurosci Lett** 1985 Jun 24;57(3):301-5

PEMOLINE

Pemoline pharmacokinetics and long term therapy in children with attention deficit disorder and hyperactivity. Collier CP, et al. **Clin Pharmacokinet** 1985 May-Jun;10(3):269-78

Treatment of chronic cocaine abuse and attention deficit disorder, residual type, with magnesium pemoline. Weiss RD et al. **Drug Alcohol Depend** 1985 May;15(1-2):69-72

PENTOBARBITAL

Effect of pentobarbital and hemorrhage on renal autoregulation. Kremser PC, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):F356-60

Fate of sodium pentobarbital in rendered products. O'Connor JJ, et al. **Am J Vet Res** 1985 Aug;46(8):1721-4

Local cerebral glucose utilization during nitrous oxide and pentobarbital anesthesia in rats. Sakabe T, et al. **Anesthesiology** 1985 Sep;63(3):262-6

Pharmacokinetics of high-dose pentobarbital in severe head trauma. Bayliff CD, et al. **Clin Pharmacol Ther** 1985 Oct;38(4):457-61

Blocking action of pentobarbital on receptors for excitatory amino acids in the guinea pig hippocampus. Sawada S. et al. **Exp Brain Res** 1985;59(2):226-31

Recovery from dispositional and pharmacodynamic tolerance after chronic pentobarbital treatment. Okamoto M, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):26-31

Studies on the effects of felodipine on the vascular resistance and reactivity in pentobarbital anesthetized dogs. Jandhyala BS. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):398-403

Estradiol-induced LH release in juvenile female rats: nembutal blocks both the decline and the exposure of nonavailable pituitary LHRH receptor sites. Smith SS, et al. **Neuroendocrinology** 1985 Sep;41(3):246-51

Pentobarbital-induced drinking does not rely on a renal dipsogen. Asin KE, et al. **Physiol Behav** 1985 Jan;34(1):151-3

A conveyor belt task for assessing visuo-motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d-amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):125-31

[Resin hemoperfusion for acute pentobarbital intoxication in rats and rabbits] Lu ZN, et al. **Chung Kuo Yao Li Hsueh Pao** 1984 Dec;5(4):281-5 (Eng. Abstr.) **(Chi)**

PEPTIDES

Effect of GRP on beta-adrenergic-stimulated gastrin and somatostatin release in the isolated rat stomach. Short GM, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):G197-202

Introduction of the dansyl group into histidine and tyrosine residues in peptides and proteins. Buchta R, et al. **Biochem Biophys Res Commun** 1985 Jul 16;130(1):350-7

Synthesis and characterization of six sequential polypeptides containing tyrosine, glutamic acid, alanine, and glycine by circular dichroism and difference spectroscopy. Zeiger AR, et al. **Biopolymers** 1985 Jul;24(7):1215-32

Immunohistochemistry of synaptic input and functional characterizations of neurons near the spinal central canal. Honda CN, et al. **Brain Res** 1985 Sep 16;343(1):120-8

An antiserum to locust adipokinetic hormone reveals a novel peptidergic system in the rat central nervous system. Sasek CA, et al. **Brain Res** 1985 Sep 16;343(1):172-5

Three dimensional analysis of retinal neuropeptides and amine in the chick. Kiyama H, et al. **Brain Res Bull** 1985 Aug;15(2):155-65

Distribution and localization of regulatory peptides. Ballesta J, et al. **CRC Crit Rev Clin Lab Sci** 1985;22(3):185-218 (250 ref.)

Effect of vagal blockade on food- and hormone-stimulated release of pancreatic polypeptide and motilin in dogs. Greenberg GR, et al. **Dig Dis Sci** 1985 Oct;30(10):946-53

Effect of passive immunization with antisera to vasoactive intestinal polypeptide and peptide histidine isoleucine amide on 5-hydroxy-L-tryptophan-induced prolactin release in rats. Kaji H, et al. **Endocrinology** 1985 Nov;117(5):1914-9

Prolonged inhibition of growth hormone secretion by peripheral injection of bombesin is mediated by somatostatin in the rat. Murphy WA, et al. **Endocrinology** 1985 Sep;117(3):1179-83

Thrombin specificity. Requirement for apolar amino acids adjacent to the thrombin cleavage site of polypeptide substrate. Chang JY. **Eur J Biochem** 1985 Sep 2;151(2):217-24

Inhibition of substance P degradation in rat brain preparations by peptide hydroxamic acids. Laufer R, et al. **Eur J Biochem** 1985 Jul 1;150(1):135-40

The proenkephalin A fragment, peptide E: central processing and CNS activity in vivo. Davis TP, et al. **Eur J Pharmacol** 1985 May 8;111(2):177-83

Use of immunoblockade to study the involvement of peptidergic afferent nerves in the intestinal vasodilatory response to capsaicin in the dog. Rózsa Z, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):59-64

beta-Endorphin and ACTH related peptides in primary cultures of rat anterior pituitary cells: evidence for different intracellular pools. Ham J, et al. **FEBS Lett** 1985 Oct 14;190(2):253-8

Peptide N-alkylamides by solid phase synthesis. Kornreich W, et al. **Int J Pept Protein Res** 1985 Apr;25(4):414-20

Opioid peptides in human adrenal: partial characterization and presence of adrenal peptide E. Boarder MR, et al. **J Clin Endocrinol Metab** 1985 Oct;61(4):658-65

Peptide diversity from exon choice: RNA processing regulation in the neuroendocrine system. Amara SG. **Mol Cell Endocrinol** 1985 Oct;42(3):191-205 (111 ref.)

The subcellular distribution of peptides immunoreactive for the carboxyl-terminal extension of cholecystokinin in rat brain. Allard LR, et al. **Neuropeptides** 1985 Jun;6(3):239-45

Catabolism of gastrin releasing peptide and substance P by gastric membrane-bound peptidases. Bunnett NW, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):277-83

Influence of vagotomy in domestic fowls on feeding activity, food passage, digestibility and satiety effects of two peptides. Savory CJ, et al. **Physiol Behav** 1984 Dec;33(6):937-44

(Glu62, Ala30, Tyr8)n serves as high-affinity substrate for tyrosylprotein sulfotransferase: a Golgi enzyme. Lee RW, et al. **Proc Natl Acad Sci USA** 1985 Sep;82(18):6143-7

Peptide-catecholamine interaction: feeding and satiety. Myers RD. **Psychopharmacol Bull** 1985;21(3):406-11

The metabolism of phenothiazine in the neonatal calf: identification of drug-polypeptide conjugates from urine. Waring RH, et al. **Xenobiotica** 1985 Jun;15(6):459-68

[Endogenous peptides in the organization of somato-vegetative responses to hypothalamic stimulation] Badikov VI, et al. **Fiziol Zh SSSR** 1985 Jul;71(7):840-7 (Eng. Abstr.) **(Rus)**

[Vasoactive peptides of the lungs] Goncharova VA. **Klin Med (Mosk)** 1985 May;63(5):59-63 (53 ref.) **(Rus)**

[Neuroendocrine action of thyroliberin, luliberin, beta-endorphin and methionine enkephalin] Babichev VN. **Usp Fiziol Nauk** 1985 Jul-Sep;16(3):52-72 (137 ref.) **(Rus)**

[Concentration of regulatory peptides in the cerebral cortex and their central activity] Ashmarin IP, et al. **Zh Vyssh Nerv Deiat** 1985 Mar-Apr;35(2):211-21 (68 ref.) **(Rus)**

PERPHENAZINE

Quantitative determination of perphenazine and its dealkylated metabolite using high-performance liquid chromatography. Larsen NE, et al. **J Chromatogr** 1985 May 31;341(1):244-50

PERSONALITY DISORDERS

Suicidal and parasuicidal behavior in borderline personality disorder. Gardner DL, et al. **Psychiatr Clin North Am** 1985 Jun;8(2):389-403 (36 ref.)

Psychodynamics and psychotherapeutic management of the self-destructive character-disordered patient. Silver D. **Psychiatr Clin North Am** 1985 Jun;8(2):357-75 (66 ref.)

Pills as transitional objects: a dynamic understanding of the use of medication in psychotherapy. Adelman SA. **Psychiatry** 1985 Aug;48(3):246-53

PHENCYCLIDINE

Hair analysis for detection of phencyclidine in newly admitted psychiatric patients. Sramek JJ, et al. **Am J Psychiatry** 1985 Aug;142(8):950-3

Binding of [3H]perhydrohistrionicotoxin and [3H]phencyclidine to the nicotinic receptor-ion channel complex of Torpedo electroplax. Inhibition by histrionicotoxins and derivatives. Aronstam RS, et al. **Biochem Pharmacol** 1985 Sep 1;34(17):3037-47

Quantitative localization of [3H]TCP binding in rat brain by light microscopy autoradiography. Sircar R, et al. **Brain Res** 1985 Sep 30;344(1):142-5

A specific alkylating ligand for phencyclidine (PCP) receptors antagonizes PCP behavioral effects. Contreras PC, et al. **Eur J Pharmacol** 1985

May 20;111(3):405-6

Phencyclidine and sigma opiate receptors in brain: biochemical and autoradiographical differentiation. Gundlach AL, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):465-6

Phencyclidine (PCP) blocks glutamate-activated postsynaptic currents. Idriss M, et al. **FEBS Lett** 1985 Sep 9;189(1):150-6

Acute and chronic behavioral interactions between phencyclidine (PCP) and amphetamine: evidence for a dopaminergic role in some PCP-induced behaviors. Greenberg BD, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):99-105

Effects of phencyclidine on active avoidance and escape in rats. Martin P, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):237-40

Comparison between locomotor activity changes produced by phencyclidine and D-amphetamine in CD-1 male mice. Stavchansky S, et al. **Res Commun Chem Pathol Pharmacol** 1985 May; 48(2):189-202

PHENCYCLIDINE ABUSE

Hair analysis for detection of phencyclidine in newly admitted psychiatric patients. Sramek JJ, et al. **Am J Psychiatry** 1985 Aug;142(8):950-3

PHENELZINE

A double-blind trial of phenelzine in bulimia. Walsh BT, et al. **J Psychiatr Res** 1985;19(2-3):485-9

PHENETHYLAMINES

Effects of amiflamine and related compounds on the accumulation of biogenic monoamines in rat brain slices in vitro and ex vivo in relation to their behavioural effects. Rényi L, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):416-26

Increased total activity in the rat after L-tryptophan plus the monoamine oxidase-A inhibitor amiflamine but not after L-tryptophan plus clorgyline. Archer T, et al. **Br J Pharmacol** 1985 Jul;85(3):581-90

Inhibition of monoamine oxidase in 5-hydroxytryptaminergic neurones by substituted p-aminophenylalkylamines. Ask AL, et al. **Br J Pharmacol** 1985 Jul;85(3):683-90

Behavioral and neurochemical effects of deprenyl and beta-phenylethylamine in Wistar rats. Greenshaw AJ, et al. **Brain Res Bull** 1985 Aug;15(2):183-9

Spin state control of cytochrome P-450 reduction and catalytic activity in a reconstituted P-450 LM2 system as induced by a series of benzphetamine analogues. Schwarze W, et al. **Chem Biol Interact** 1985 Jul;54(2):127-41

Examination of the bronchoconstrictor response of guinea-pig isolated lung to beta-phenylethylamine. Hawthorn MH, et al. **Gen Pharmacol** 1985;16(4):371-8

Monoamine oxidase-A selective inhibition in human hypothalamus and liver in-vitro by amiflamine and its metabolites. Tipton KF, et al. **J Pharm Pharmacol** 1985 May;37(5):352-4

Characterization of alpha 2-adrenoceptor binding properties of imidazoline-like drugs, azoloazepine derivatives and beta-phenethylamine-like drugs in human platelet membranes. Vago T, et al. **J Pharm Pharmacol** 1985 Aug;37(8):593-6

Trace amines inhibit the electrically evoked release of [3H]acetylcholine from slices of rat striatum in the presence of pargyline: similarities between beta-phenylethylamine and amphetamine. Baud P, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):220-9

Comparison of brown adipose tissue thermogenesis induced by congeners and isomers of phenylpropanolamine. Wellman PJ, et al. **Life Sci** 1985 Sep 16;37(11):1023-8

Beta-phenylethylamines and the isoquinoline alkaloids. Bentley KW. **Nat Prod Rep** 1984 Aug;1(4):355-70 (473 ref.)

Tyramine pressor sensitivity changes during deprenyl treatment. Sunderland T, et al. **Psychopharmacology (Berlin)** 1985;86(4):432-7

PHENOBARBITAL

Pentobarbital inhibits the vasoconstrictor response to renal venous pressure elevation in the dog kidney. Abildgaard U. **Acta Physiol Scand** 1985 Aug;124(4):625-7

Transcriptional regulation of rat liver glutathione S-transferase genes by phenobarbital and 3-methylcholanthrene. Ding VD, et al. **Arch Biochem Biophys** 1985 Aug 1;240(2):553-9

Turnover of messenger RNA, apoprotein and haem of cytochrome P-450b + e induced by phenobarbitone in rat liver. Ravishankar H, et al. **Biochem J** 1985 Jul 1;229(1):73-9

Effects of phenobarbitone and beta-naphthoflavone on hepatic microsomal drug metabolising enzymes of the male beagle dog. McKillop D. **Biochem Pharmacol** 1985 Sep 1;34(17):3137-42

Effects of detergent on substrate binding and spin state of purified liver microsomal cytochrome P-450LM2 from phenobarbital-treated rabbits. Wagner SL, et al. **Biochemistry** 1985 Jul 2;24(14):3809-14

Heteroassociation of O- and N-isopropyl derivatives of barbital and phenobarbital with 9-ethyladenine. Gentric E, et al. **Chem Biol Interact** 1985 Jun;54(1):117-25

Ligand displacement immunoassay--demonstration of its use for the measurement of serum phenobarbital and phenytoin. Hinds JA, et al. **Clin Chim Acta** 1985 Jul 15;149(2-3):105-15

Regulation of hepatic monooxygenases by phenobarbital, 3-methylcholanthrene, and polychlorinated biphenyls in rapid and slow acetylator mice. Elves RG, et al. **Drug Metab Dispos** 1985 May-Jun; 13(3):354-8

Differential regulation of pulsatile luteinizing hormone (LH) and follicle-stimulating hormone secretion in ovariectomized rats disclosed by treatment with a LH-releasing hormone antagonist and phenobarbital. De Paolo LV. **Endocrinology** 1985 Nov; 117(5):1826-33

Nuclear ADP-ribosyl transferase activity correlates with induction of P-450 monooxygenases by phenobarbital in rat liver microsomes. Lechner MC, et al. **Eur J Biochem** 1985 Sep 16;151(3):621-4

Separate site(s) of action of optical isomers of 1-methyl-5-phenyl-5-propylbarbituric acid with opposite pharmacological activities at the GABA receptor complex. Ticku MK, et al. **Eur J Pharmacol** 1985 May 28;112(1):1-9

Long-term survival of functional hepatocytes from adult rat in the presence of phenobarbital in primary culture. Miyazaki M, et al. **Exp Cell Res** 1985 Jul;159(1):176-90

Inducibility of the hepatic microsomal monooxygenase system experimentally reduced to a minimum amount/activity. Effect of hypophysectomy, partial hepatectomy and phenobarbital/toluene treatment on the hepatic polysubstrate monooxygenase system in rats. Ungváry G, et al. **Exp Pathol** 1985;27(4):207-20

The modulation of growth of normal rat liver epithelial cells in calcium-poor medium by epidermal growth factor, phenobarbital, phorbol ester, and retinoic acid. Tsao MS, et al. **In Vitro Cell Dev Biol** 1985 May;21(5):249-53

Comparison of the impact of continuous and intermittent exposure to vinyl chloride, including phenobarbital effect. Jedrychowski RA, et al. **J Hyg Epidemiol Microbiol Immunol** 1985;29(2):111-20

Comparison of equilibrium dialysis, ultrafiltration, and gel permeation chromatography for the determination of free fractions of phenobarbital and phenytoin. Melten JW, et al. **J Pharm Sci** 1985 Jun;74(6):692-4

Natural (-)- and unnatural (+)-enantiomers of morphine: comparative metabolism and effect of morphine and phenobarbital treatment. Rane A, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):761-5

Absorption kinetics and bioavailability of phenobarbital after oral administration to dogs. Al-Tahan F, et al. **J Vet Pharmacol Ther** 1985 Jun;8(2):205-7

Increased anticonvulsant effect of phenobarbital with age in mice--a possible pharmacological index for brain aging. Kitani K, et al. **Life Sci** 1985 Oct 14;37(15):1451-60

Isolation and comparison of four cytochrome P-450 enzymes from phenobarbital-induced rat liver: three forms possessing identical NH2-terminal sequences. Backes WL, et al. **Pharmacology** 1985; 31(3):155-69

Pulmonary cytochromes P-450 from rabbits treated with phenobarbital. Ueng TH, et al. **Pharmacology** 1985;31(1):40-9

The comparative potency of phenobarbital and five 1,3-propanediol dicarbamates for hepatic cytochrome P450 induction in rats. Segelman FH, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jun; 48(3):467-70

Effects of 3-methylcholanthrene and phenobarbital on the capacity of embryos to bioactivate teratogens during organogenesis. Juchau MR, et al. **Toxicol Appl Pharmacol** 1985 Aug;80(1):137-46

Effect of promethazine and isosafrole on rat-hepatic microsomal mono-oxygenase activity: comparison with classic inducers phenobarbitone and beta-naphthoflavone. Taylor G, et al. **Xenobiotica** 1985 Mar;15(3):243-9

PHENOTHIAZINE TRANQUILIZERS

Ten-year follow-up of schizophrenic patients on pipothiazine palmitate. Imlah NW, et al. **Curr Med Res Opin** 1985;9(7):449-53

Agranulocytosis in the course of phenothiazine therapy: case reports. Yassa R. **J Clin Psychiatry** 1985 Aug;46(8):341-3

Radioimmunoassay of tricyclic antidepressant and some phenothiazine drugs in forensic toxicology. Robinson K, et al. **J Immunoassay** 1985; 6(1-2):11-22

Phenothiazine associated hyperthermia. A case report. Roberts DE. **J Tenn Med Assoc** 1985 Aug;78(8):489-90

[The affinity of aromatic fluoride derivatives of phenothiazine neuroleptics to spiroperidol binding sites of dopamine receptors by the radioligand technic in vitro] Oelssner W Jr, et al. **Pharmazie** 1985 May; 40(5):341-2 (Eng. Abstr.) **(Ger)**

[Parenteral form of pipothiazine in the treatment of endogenous psychoses] Matkowski K, et al. **Psychiatr Pol** 1984 Nov-Dec;18(6):567-70 (Eng. Abstr.) **(Pol)**

PHENOTHIAZINES

Unusual electrochemical behaviour of a new phenothiazine. Kauffmann

JM, et al. **Analyst** 1985 Apr;110(4):349–51

Inhibition of the hydro–osmotic response to vasopressin and hypertonicity by phenothiazines and W7, calmodulin antagonists. Yorio T, et al. **Gen Pharmacol** 1985;16(4):347–53

Sheep–erythrocyte–capping by human T–lymphocytes. Pharmacological inhibition by phenothiazine drugs. Brohée D, et al. **Int J Immunopharmacol** 1985;7(5):739–46

Rapid microchemical identification of four phenothiazine antiemetics with gold bromide and iodine–potassium iodide reagents: collaborative study. Rabkin M. **J Assoc Off Anal Chem** 1985 May–Jun;68(3):527–9

Release of superoxide and change in morphology by neutrophils in response to phorbol esters: antagonism by inhibitors of calcium–binding proteins. Robinson JM, et al. **J Cell Biol** 1985 Sep;101(3):1052–8

Thionin: spectrophotometry and thin–layer chromatography in relation to biological staining. Allison RT, et al. **Med Lab Sci** 1985 Jul; 42(3):213–20

Toxicity and interaction of topical organophosphate insecticide dichlorvoscrotoxyphos and phenothiazine anthelmintic in sheep previously exposed to both drugs. Mohammad FK, et al. **Vet Hum Toxicol** 1985 Jun;27(3):181–4

The metabolism of phenothiazine in the neonatal calf: identification of drug–polypeptide conjugates from urine. Waring RH, et al. **Xenobiotica** 1985 Jun;15(6):459–68

[Positive reaction of serum anti–DNA antibody induced by phenothiazines in schizophrenic patients] Yang JS. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Dec; 17(6):333–5 (Eng. Abstr.) **(Chi)**

[Oxidation of phenothiazine and its N–methyl derivative by the combination of iodobenzene and vanadium acetylacetonate] Pautet F, et al. **Pharmazie** 1985 Mar;40(3):202–3 **(Fre)**

[Effect of etatsizin on blood coagulability and the anticoagulant effect of heparin] Petrov AD. **Farmakol Toksikol** 1985 Jul–Aug; 48(4):112–4 (Eng. Abstr.) **(Rus)**

PHENOXYBENZAMINE

The effects of phenoxybenzamine on specific binding and function of central alpha–adrenoceptors in the rabbit. Hamilton CA, et al. **Brain Res** 1985 Sep 30;344(1):89–95

Effect of phenoxybenzamine and clonidine on the adrenergic receptor in the rat brain; histofluorescence and ultrastructure examinations. Wawrzyniak M, et al. **Folia Histochem Cytobiol** 1985;23(1–2):91–2

Influence of phenoxybenzamine on the stereotyped behaviour induced by fencamfamine in rats: evidence for a qualitative alteration. Bernardi MM, et al. **Gen Pharmacol** 1985;16(4):403–5

Effect of phenoxybenzamine on indomethacin induced systemic vasoconstriction in dogs. Anderson FL, et al. **Prostaglandins Leukotrienes Med** 1985 Jun;18(3):287–92

PHENYLALANINE

Effect of cocaine dependence on plasma phenylalanine and tyrosine levels and on urinary MHPG excretion. Tennant FS Jr. **Am J Psychiatry** 1985 Oct;142(10):1200–1

L–phenylalanine [letter] Simonson M. **J Clin Psychiatry** 1985 Aug; 46(8):355

Biopterin, neopterin and tyrosine responses to combined oral phenylalanine and tetrahydrobiopterin loading tests in two normal children and in a girl with partial biopterin deficiency. Lykkelund C, et al. **J Inherited Metab Dis** 1985;8 Suppl 2:95–6

PHENYLPROPANOLAMINE

Therapeutic doses of phenylpropanolamine increase supine systolic blood pressure. Pentel PR, et al. **Int J Obes** 1985;9(2):115–9

Comparison of brown adipose tissue thermogenesis induced by congeners and isomers of phenylpropanolamine. Wellman PJ, et al. **Life Sci** 1985 Sep 16;37(11):1023–8

PHENYTOIN

Resistance to metocurine–induced neuromuscular blockade in patients receiving phenytoin. Ornstein E, et al. **Anesthesiology** 1985 Sep; 63(3):294–8

Plasma protein binding of salicylic acid, phenytoin, chlorpromazine, propranolol and pethidine using equilibrium dialysis and ultracentrifugation. Verbeeck RK, et al. **Arzneimittelforschung** 1985; 35(6):903–6

The effects of sucralfate upon phenytoin absorption in man. Smart HL, et al. **Br J Clin Pharmacol** 1985 Sep;20(3):238–40

Suppression by phenytoin of convulsant–induced afterdischarges at presynaptic nerve terminals. David G, et al. **Brain Res** 1985 Jul 22; 339(1):57–65

Inhibitory effect of phenytoin on intracellular cyclic nucleotide and calcium changes during pentylenetetrazole–induced bursting activity in snail neurons. Sugaya E, et al. **Brain Res** 1985 Aug 26;341(2):313–9

Specific binding of [3H]phenytoin in the human brain. Spero L. **Can J Physiol Pharmacol** 1985 May;63(5):517–8

In situ molecular weight determination of rat brain [3H]phenytoin binding sites. Spero L. **Can J Physiol Pharmacol** 1985 May;63(5):515–6

Liver DNA synthesis after phenytoin injection in adult NMRI mice. Lombard MN, et al. **Cell Tissue Kinet** 1985 Sep;18(5):569–71

Ligand displacement immunoassay––demonstration of its use for the measurement of serum phenobarbital and phenytoin. Hinds JA, et al. **Clin Chim Acta** 1985 Jul 15;149(2–3):105–15

Phenytoin once–daily dosing in geriatric patients [letter] Clark BG. **Drug Intell Clin Pharm** 1985 Jul–Aug;19(7–8):584

In vitro adsorption of sodium phenytoin by anion exchange resin [letter] Laurent D, et al. **Drug Intell Clin Pharm** 1985 Jul–Aug; 19(7–8):584–5

Inhibition of microsomal phenytoin metabolism by nafimidone and related imidazoles. Potency and structural considerations. Kapetanovic IM, et al. **Drug Metab Dispos** 1985 Jul–Aug;13(4):430–7

Phenytoin enhances epoxide metabolism in human fetal liver cultures. Rane A, et al. **Drug Metab Dispos** 1985 May–Jun;13(3):382–5

Aplastic anaemia induced by intravenous phenytoin and lidocaine administration [letter] Tomita S, et al. **Eur J Pediatr** 1985 Jul; 144(2):207–8

Analysis of the toxicologically relevant metabolites of phenytoin in biological samples by high–performance liquid chromatography. Lum JT, et al. **J Chromatogr** 1985 Feb 27;338(1):242–8

H–2 histocompatibility region influences the inhibition of arachidonic acid cascade by dexamethasone and phenytoin in mouse embryonic palates. Gupta C, et al. **J Craniofac Genet Dev Biol** 1985;5(3):277–85

Diphenylhydantoin inhibits parathyroid hormone and prostaglandin E2–stimulated bone resorption in mouse calvaria without affecting cyclic AMP formation. Lerner U, et al. **J Oral Pathol** 1985 Sep; 14(8):644–53

A comparative study of the bioavailability of five different phenytoin preparations. Hirji MR, et al. **J Pharm Pharmacol** 1985 Aug; 37(8):570–2

Comparison of equilibrium dialysis, ultrafiltration, and gel permeation chromatography for the determination of free fractions of phenobarbital and phenytoin. Melten JW, et al. **J Pharm Sci** 1985 Jun;74(6):692–4

Effects of stimulation and diphenylhydantoin on the intracellular sodium activity in Purkinje fibres of sheep heart. Ellis D. **J Physiol (Lond)** 1985 May;362:331–48

Phenytoin–dexamethasone: a possible drug–drug interaction [letter] Wong DD, et al. **JAMA** 1985 Oct 18;254(15):2062–3

Phenytoin absorption in adults: effect of aging [letter] Ensom RJ, et al. **N Engl J Med** 1985 Sep 12;313(11):697

Modulation of specific [3H]phenytoin binding by benzodiazepines. Spero L. **Neurochem Res** 1985 Jun;10(6):755–65

Extent of urinary excretion of p–hydroxyphenytoin in healthy subjects given phenytoin. Dickinson RG, et al. **Ther Drug Monit** 1985; 7(3):283–9

Rapid protein determinations on ultrafiltrates prepared for free phenytoin quantification. Turley CP, et al. **Ther Drug Monit** 1985;7(3):313–4

[Dental plaque and gingival hyperplasia due to Dilantin] Maisonneuve C. **J Dent Que** 1985 Feb;22:55–7 (47 ref.) (Eng. Abstr.) **(Fre)**

[Effect of phenytoin on Purkinje cells in the cerebellum] Nikolarakis K, et al. **Zentralbl Allg Pathol** 1985;130(3):229–32 (Eng. Abstr.) **(Ger)**

[Immunopathological studies of phenytoin–induced gingival hyperplasia] Kassai Y, et al. **Nippon Shishubyo Gakkai Kaishi** 1985 Mar; 27(1):197–205 (Eng. Abstr.) **(Jpn)**

[Hydantoin gingival hyperplasia: diagnosis, prevention and treatment] Martos Molino F, et al. **Rev Actual Estomatol Esp** 1984 Sep; 44(340):23–30 **(Spa)**

[Experimental study of the effect of the administration of diphenyl hydantoin and estrogens in rats. III. Microbiological aspects of variations in the gingival flora in rats treated with estrogens] Bascones A, et al. **Rev Esp Estomatol** 1984 Sep–Oct;32(5):319–28 **(Spa)**

[Experimental study of the effect of the administration of diphenyl hydantoin and estrogens. II. Histopathological aspects of gingival changes in rats treated with diphenylhydantoin] Hernandez Vallejo G, et al. **Rev Esp Estomatol** 1984 Jul–Aug;32(4):223–32 **(Spa)**

[Morphological aspects of gingival hyperplasia caused by hydantoin] Sampedro Nuno A, et al. **Rev Esp Estomatol** 1985 Jan–Feb; 33(1):39–44 **(Spa)**

PHOBIC DISORDERS

Imipramine in the treatment of agoraphobia: dose–response relationships. Mavissakalian M, et al. **Am J Psychiatry** 1985 Sep;142(9):1032–6

Platelet monoamine oxidase activity in patients with panic disorder. Gorman J, et al. **Biol Psychiatry** 1985 Aug;20(8):852–7

Treatment of social phobia with atenolol. Gorman JM, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):298–301

Efficacy and tolerability of sustained–release clomipramine (Anafranil SR) in the treatment of phobias: a comparison with the conventional formulation of clomipramine (Anafranil). Allsopp LF, et al. **J Int Med Res** 1985;13(4):203–8

Effect of beta–receptor blockade on anxiety with reference to the three–systems model of phobic behavior. Fagerström KO, et al.

Neuropsychobiology 1985;13(4):187–93

Agoraphobia. Is fear the basis of symptoms? Laybourne PC Jr, et al. **Postgrad Med** 1985 Oct;78(5):109–12, 114, 117–8

Psychopharmacological treatment of social phobia. Liebowitz MR, et al. **Psychopharmacol Bull** 1985;21(3):610–4

PHYSOSTIGMINE

The first reversal of curare. A translation of Pal's original paper, 'Physostigmine, an antidote to curare', 1900. Nickalls RW, et al. **Anaesthesia** 1985 Jun;40(6):572–5

Sensitive liquid chromatographic method for physostigmine in biological fluids using dual-electrode electrochemical detection. Whelpton R, et al. **J Chromatogr** 1985 Jun 14;341(2):361–71

Interactions of edrophonium, physostigmine and methanesulfonyl fluoride with the snake end-plate acetylcholine receptor-channel complex. Fiekers JF. **J Pharmacol Exp Ther** 1985 Sep;234(3):539–49

A comparison of physostigmine and soman using taste aversion and nociception. Romano JA, et al. **Neurobehav Toxicol Teratol** 1985 May–Jun;7(3):243–9

[Differences in the cholinergic effects of eserine and pilocarpine on the uvea and retina of the bovine eye] Kováčik L, et al. **Bratisl Lek Listy** 1985 Jul;84(1):45–9 (Eng. Abstr.) **(Slo)**

PILOCARPINE

Controlled release of pilocarpine hydrochloride from ethylene-vinyl alcohol copolymer matrices. Hou WM, et al. **Chem Pharm Bull (Tokyo)** 1985 Mar;33(3):1242–8

Effects of the substance P antagonist [D-Arg1,D-Pro2,D-Trp7,9,Leu11]SP on miosis caused by echothiophate iodide or pilocarpine hydrochloride. Mandahl A. **Eur J Pharmacol** 1985 Aug 15;114(2):121–7

Pilocarpine used to stimulate normal saliva production. **J Am Dent Assoc** 1985 Aug;111(2):310

Use of pilocarpine intraocularly [letter] Girard LJ. **J Am Intraocul Implant Soc** 1985 Jul;11(4):390

Pilocarpic acid esters as novel sequentially labile pilocarpine prodrugs for improved ocular delivery. Bundgaard H, et al. **J Med Chem** 1985 Aug;28(8):979–81

pH of mucus in rabbit trachea: cholinergic stimulation and block. Gatto LA. **Lung** 1985;163(2):109–15

Central muscarinic receptors and male rat sexual behavior: facilitation by oxotremorine but not arecoline or pilocarpine in methscopolamine pretreated animals. Ahlenius S, et al. **Psychopharmacology (Berlin)** 1985; 87(2):127–9

Glycoprotein secretion from mouse gallbladder principal cells after chronic variation in parasympathetic activity. A morphometric study after vagotomy and cholinergic superstimulation. Axelsson H, et al. **Scand J Gastroenterol** 1985 Aug;20(6):727–33

[The application of computer to volumetric analysis of drugs: the assay of weakly acidic water-soluble drugs] Luo GA, et al. **Yao Hsueh Hsueh Pao** 1985 Feb;20(2):146–50 (Eng. Abstr.) **(Chi)**

[Biopharmaceutics of ophthalmic drugs] Etter JC, et al. **Klin Monatsbl Augenheilkd** 1985 Jun;186(6):417–20 (Eng. Abstr.)**(Fre)**

[Determination of ethylmorphine chloride, pilocarpine chloride and tetracaine chloride in drops and ointments for the eye] Banović V, et al. **Vojnosanit Pregl** 1985 May–Jun;42(3):202–5 (Eng. Abstr.) **(Ser)**

[Differences in the cholinergic effects of eserine and pilocarpine on the uvea and retina of the bovine eye] Kováčik L, et al. **Bratisl Lek Listy** 1985 Jul;84(1):45–9 (Eng. Abstr.) **(Slo)**

PITUITARY HORMONE RELEASING HORMONES

Desensitization of testicular ornithine decarboxylase to gonadotropin releasing hormone and gonadotropic hormones. Madhubala R, et al. **Biochem Int** 1985 Aug;11(2):225–32

Pulsatile administration of gonadotropin-releasing hormone to anestrous sows: endocrine changes associated with GnRH-induced and spontaneous estrus. Armstrong JD, et al. **Biol Reprod** 1985 Sep; 33(2):375–80

A suppression of gonadotropin secretion by cortisol in castrated male rhesus monkeys (Macaca mulatta) mediated by the interruption of hypothalamic gonadotropin-releasing hormone release. Dubey AK, et al. **Biol Reprod** 1985 Sep;33(2):423–31

The effects of cycloheximide on in vitro response of Rana pipiens pituitaries to continuously superfused gonadotropin-releasing hormone. Porter DA. **Biol Reprod** 1985 Sep;33(2):393–400

Gonadotropin-releasing hormone within the organum vasculosum lamina terminalis in the ovariectomized, estrogen/progesterone-treated rat: a quantitative immunocytochemical study using image analysis. Rothfeld JM, et al. **Brain Res** 1985 Jul 15;338(2):309–15

LH secretion in response to gonadotropin releasing hormone (GnRH) by superfused pituitaries from two species of turtles. Licht P, et al. **Gen Comp Endocrinol** 1985 Sep;59(3):442–8

Effects of dihydrotestosterone benzoate administration on gonadotropin secretion in ovariectomized pony mares. Garza F Jr, et al. **J Anim Sci** 1985 Jul;61(1):240–4

Changes of luteinizing hormone and progesterone for dairy cows after gonadotropin-releasing hormone at first postpartum breeding. Lee CN, et al. **J Dairy Sci** 1985 Jun;68(6):1463–70

Role of GnRH in the maturation of pituitary gonadotroph function. Clayton RN. **J Reprod Fertil** 1985 Sep;75(1):307–15 (62 ref.)

Plasma LH and FSH responses and ovarian activity in prepubertal heifers treated with repeated injections of low doses of GnRH for 72 h. McLeod BJ, et al. **J Reprod Fertil** 1985 Jul;74(2):589–96

Role of GnRH in the regulation of pituitary GnRH receptors in female mice. Naik SI, et al. **J Reprod Fertil** 1985 Jul;74(2):605–14

Evidence for a pituitary site of gonadal steroid stimulation of GnRH receptors in female mice. Naik SI, et al. **J Reprod Fertil** 1985 Jul; 74(2):615–24

Ovarian hyperstimulation with exogenous pulsatile gonadotropin releasing hormone therapy. Corenblum B, et al. **J Ultrasound Med** 1985 Aug; 4(8):405–10

Electrophysiological recordings from gonadotrophs. Evidence for Ca2+ channels mediated by gonadotrophin-releasing hormone. Mason WT, et al. **Neuroendocrinology** 1985 Sep;41(3):258–68

A new family member for gonadotropin-releasing hormone. Sherwood NM, et al. **Neuropeptides** 1985 Jun;6(3):205–14

[Pulsed administration of gonadoliberine (GnRH) in the treatment of anovulation] Jaffiol C, et al. **Bull Acad Natl Med (Paris)** 1985 Jan; 169(1):95–8 (Eng. Abstr.) **(Fre)**

[Cellular biochemistry of hypophysiotropic peptides. II. Liberation, action and inactivation] Charli JL, et al. **Bol Estud Med Biol** 1983 Jul–Oct; 32(7–8 Suppl 1):243–52 **(Spa)**

[Biochemistry of hypophysiotropic peptides. I. Biosynthesis and its regulation] Joseph-Bravo P, et al. **Bol Estud Med Biol** 1983 Jul–Oct; 32(7–8 Suppl 1):233–41 (Eng. Abstr.) **(Spa)**

PITUITARY HORMONES

Salmonid melanin-concentrating hormone inhibits corticotrophin release. Baker BI, et al. **J Endocrinol** 1985 Aug;106(2):R5–8

[Intermediate lobe of the amphibian pituitary gland: an endocrine gland with multiple secretions and under multi-hormonal control] Tonon MC, et al. **Ann Endocrinol (Paris)** 1985;46(2):69–87 (126 ref.) (Eng. Abstr.) **(Fre)**

PITUITARY HORMONES, ANTERIOR

Differential secretion of O-glycosylated gonadotropin alpha-subunit and luteinizing hormone (LH) in the presence of LH-releasing hormone. Corless CL, et al. **Endocrinology** 1985 Oct;117(4):1699–706

Effect of acute ether stress on monoamine metabolism in median eminence and discrete hypothalamic nuclei of the rat brain and on anterior pituitary hormone secretion. Johnston CA, et al. **Neuroendocrinology** 1985 Jul;41(1):83–8

[Measurement of basal plasma levels of 3 anterior pituitary hormones during acute or chronic treatment with tricyclic antidepressants] Goyot C, et al. **Encephale** 1985 Mar–Apr;11(2):45–51 (Eng. Abstr.) **(Fre)**

PITUITARY HORMONES, POSTERIOR

Conformational flexibility of neurophysin as investigated by local motions of fluorophores. Relationships with neurohypophyseal hormone binding. Rholam M, et al. **Biochemistry** 1985 Apr 9;24(8):1928–33

PREDNISONE

[Effect of corticosteroid therapy of various durations on urinary excretion of norepinephrine] Jelić S, et al. **Srp Arh Celok Lek** 1984 Nov–Dec; 112(11–12):1135–44 (Eng. Abstr.) **(Scc)**

[Urinary excretion of epinephrine in patients on short-term and long-term corticosteroid therapy] Jelić S, et al. **Srp Arh Celok Lek** 1985 Jan; 113(1):29–40 (Eng. Abstr.) **(Scc)**

PROCHLORPERAZINE

A comparison of the antiemetic efficacy of prochlorperazine and metoclopramide for the treatment of cisplatin-induced emesis: a prospective, randomized, double-blind study. Carr BI, et al. **J Clin Oncol** 1985 Aug;3(8):1127–32

PROGESTERONE

Progesterone decreases the responsiveness of ovine pituitary cultures to luteinizing hormone-releasing hormone. Batra SK, et al. **Endocrinology** 1985 Oct;117(4):1436–40

Effects of ovarian hormones on the concentrations of immunoreactive neuropeptide Y in discrete brain regions of the female rat: correlation with serum luteinizing hormone (LH) and median eminence LH-releasing hormone. Crowley WR, et al. **Endocrinology** 1985 Sep; 117(3):1151–5

Effect of local GABA administration on rat ovarian blood flow, and on progesterone and estradiol secretion. Erdő S, et al. **Eur J Pharmacol** 1985 May 20;111(3):397–400

Evidence that progesterone binding uteroglobin is similar to myosin alkali light chain. Baker ME. **FEBS Lett** 1985 Sep 23;189(2):188–94

Progesterone has no effect on serum thyroxine-binding globulin concentration in men. Chen JJ, et al. **J Clin Endocrinol Metab** 1985 Nov;61(5):983–5

Changes of luteinizing hormone and progesterone for dairy cows after gonadotropin-releasing hormone at first postpartum breeding. Lee CN, et al. **J Dairy Sci** 1985 Jun;68(6):1463–70

Antioestrogen inhibition of oestradiol-induced alterations in hypothalamic noradrenaline turnover. Hiemke C, et al. **J Endocrinol** 1985 Jul; 106(1):37–42

Time-dependent effects of oestradiol and progesterone on hypothalamic catecholamine turnover in ovariectomized rats. Hiemke C, et al. **J Endocrinol** 1985 Sep;106(3):303–9

Catechol oestradiol control of FSH-stimulated granulosa cell steroidogenesis. Hudson KE, et al. **J Endocrinol** 1985 Jul; 106(1):R1–4

Hormonal modulation of the responsiveness of midbrain central gray neurons to LH-RH. Chan A, et al. **Neuroendocrinology** 1985 Aug; 41(2):163–8

Progesterone and the control of functional luteolysis, of secretion of prolactin and of pituitary LHRH responsiveness. A study with pseudopregnant rats kept in alternating and constant lighting conditions. Schuiling GA, et al. **Neuroendocrinology** 1985 Jul;41(1):52–9

Progesterone action on the LHRH and the nigrostriatal dopamine neuronal systems: in vitro and in vivo studies. Ramirez VD, et al. **Recent Prog Horm Res** 1985;41:421–72 (110 ref.)

Current concepts in premenstrual syndrome. Ullman LE. **RI Med J** 1985 Jun;68(6):269–72

[Effect of ACTH on the corticosteroid and progesterone levels in female hamadryas baboons in relation to the menstrual cycle phase] Todua TN, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):135–7 (Eng. Abstr.) **(Rus)**

[Inhibitory effect of progesterone on the stimulation of tryptophan pyrrolase and tyrosine aminotransferase by endogenous corticosteroids in the liver of female rats] Németh S, et al. **Bratisl Lek Listy** 1985 Jul;84(1):3–10 (Eng. Abstr.) **(Slo)**

PROLACTIN

Side effects of drugs stimulating prolactin secretion on the behavior of male rats. Drago F, et al. **Arch Int Pharmacodyn Ther** 1985 Aug; 276(2):271–8

A new in vitro assay system for prolactin-releasing activity and its application for demonstration of porcine hypothalamic prolactin-releasing factor (PRF). Nomura M, et al. **Asia Oceania J Obstet Gynaecol** 1985 Jun;11(2):271–8

Bromoergocryptine decreases serum prolactin and delays sexual maturation in male golden hamsters. Stroud CM, et al. **Biol Reprod** 1985 Jun;32(5):1191–9

Influence of bromocriptine on plasma prolactin, human placental lactogen, beta-HCG and steroid hormones in early human pregnancy. Tolino A, et al. **Biol Res Pregnancy Perinatol** 1985;6(2):70–2

Secretory granules of prolactin cells of neonatally thyroidectomized female rats. Shiino M, et al. **Cell Tissue Res** 1985;242(1):179–83

The interaction of trh and dopaminergic mechanisms in the regulation of stimulated prolactin release in man. Ho KY, et al. **Clin Endocrinol (Oxf)** 1985 Jul;23(1):7–16

Plasma concentrations of arginine vasotocin, prolactin, aldosterone and corticosterone in relation to oviposition and dietary NaCl in the domestic fowl. Rice GE, et al. **Comp Biochem Physiol [A]** 1985; 81(4):769–77

Growth hormone, thyrotropin and prolactin responses to simultaneous administration of human growth hormone-releasing factor and thyrotropin releasing hormone in the bovine. Hodate K, et al. **Endocrinol Jpn** 1985 Jun;32(3):375–83

Stimulation of the adenosine 3',5'-monophosphate and the Ca2+ messenger systems together reverse dopaminergic inhibition of prolactin release. Delbeke D, et al. **Endocrinology** 1985 Aug;117(2):439–46

Hyperprolactinemia inhibits gonadotropin-releasing hormone (GnRH) stimulation of the number of pituitary GnRH receptors. Garcia A, et al. **Endocrinology** 1985 Sep;117(3):954–9

Effect of passive immunization with antisera to vasoactive intestinal polypeptide and peptide histidine isoleucine amide on 5-hydroxy-L-tryptophan-induced prolactin release in rats. Kaji H, et al. **Endocrinology** 1985 Nov;117(5):1914–9

Thyrotropin-releasing hormone and epidermal growth factor stimulate prolactin synthesis by a pathway(s) that differs from that used by phorbol esters: dissociation of actions by calcium dependency and additivity. Ramsdell JS, et al. **Endocrinology** 1985 Nov; 117(5):2050–60

Pantethine, a cysteamine precursor, depletes immunoreactive somatostatin and prolactin in the rat. Reichlin S, et al. **Endocrinology** 1985 Aug; 117(2):492–5

The effects of growth hormone, prolactin, corticotropin, and thyrotropin on the production and secretion of somatostatin by hypothalamic cells in vitro. Robbins RJ, et al. **Endocrinology** 1985 Aug;117(2):538–43

Histidyl-proline-diketopiperazine (cyclo-his-pro) inhibits the suckling- and domperidone-induced transformation of prolactin in the lactating rat. Shyr SW, et al. **Endocrinology** 1985 Nov;117(5):2170–5

Interaction of SCH 23390, a D-1-selective antagonist, with the anterior pituitary D-2 receptors and prolactin secretion in the rat. Apud JA, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):187–93

Phorbol esters affect pituitary growth hormone (GH) and prolactin release: the interaction with GH releasing factor, somatostatin and bromocriptine. Summers ST, et al. **Eur J Pharmacol** 1985 May 20; 111(3):371–6

The influence of thyrotropin releasing hormone on in vivo prolactin release and in vitro prolactin, luteinizing hormone, and growth hormone release from dispersed pituitary cells of the young turkey (Meleagris gallopavo). Fehrer SC, et al. **Gen Comp Endocrinol** 1985 Jul; 59(1):64–72

Hypothalamic and serum factors influence on prolactin and luteinizing hormone release by the pituitary gland of the young turkey (Meleagris gallopavo). Fehrer SC, et al. **Gen Comp Endocrinol** 1985 Jul; 59(1):73–81

Somatostatin-like immunoreactivity in the pituitary and brain of three teleost fish species: somatostatin as a potential regulator of prolactin cell function. Grau EG, et al. **Gen Comp Endocrinol** 1985 Sep; 59(3):350–7

Thyroid function in adult rough-skinned newts (Taricha granulosa): effects of hypophysectomy and hormone replacement. Specker JL, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):326–31

Evidence for serotoninergic control of exercise-induced prolactin secretion. De Meirleir K, et al. **Horm Metab Res** 1985 Jul; 17(7):380–1

Gonadal steroids deficiency and prolactin response to a met-enkephalin analog in man. Foresta C, et al. **Horm Metab Res** 1985 Jun; 17(6):319–20

In vivo and in vitro effects of cholecystokinin octapeptide on the release of prolactin in rats. Matsumura M, et al. **Horm Metab Res** 1985 Jun; 17(6):293–7

Effect of acute intravenous growth hormone-releasing factor on plasma prolactin in short children and patients with growth hormone deficiency. Chatelain PG, et al. **Horm Res** 1985;22(1–2):46–51

Pregnancy despite continued elevation of prolactin levels while on bromergocryptine. Corson SL, et al. **Int J Gynaecol Obstet** 1985 Apr; 23(2):105–7

Molecular mechanisms of phorbol ester, thyrotropin-releasing hormone, and growth factor stimulation of prolactin gene transcription. Murdoch GH, et al. **J Biol Chem** 1985 Sep 25;260(21):11852–8

Prolactin permits the expression of a circadian variation in lipogenic responsiveness to insulin in hepatocytes of the golden hamster (Mesocricetus auratus). Cincotta AH, et al. **J Endocrinol** 1985 Aug; 106(2):173–6

Prolactin permits the expression of a circadian variation in insulin receptor profile in hepatocytes of the golden hamster (Mesocricetus auratus). Cincotta AH, et al. **J Endocrinol** 1985 Aug;106(2):177–81

Prolactin in cerebrospinal fluid increases the synthesis and release of hypothalamic gamma-aminobutyric acid. Locatelli V, et al. **J Endocrinol** 1985 Sep;106(3):323–8

Effect of immunoneutralization of thyrotrophin-releasing hormone on the release of thyrotrophin and prolactin during suckling or in response to electrical stimulation of the hypothalamus in the anaesthetized rat. Sheward WJ, et al. **J Endocrinol** 1985 Jul;106(1):113–9

Prolactin influences sexual behavior during aging. Ferrara N, et al. **J Endocrinol Invest** 1985;8 Suppl 2:23–32

Histamine H1 receptor participation in the control of prolactin secretion in postpartum. Messinis IE, et al. **J Endocrinol Invest** 1985 Apr; 8(2):143–6

Effect of 1,25-dihydroxyvitamin D3 and nifedipine on prolactin release in normal man. Verbeelen D, et al. **J Endocrinol Invest** 1985 Apr; 8(2):103–6

Effects of the 1,5-benzodiazepine clobazam on pituitary hormones in the male rat. Valli M, et al. **Methods Find Exp Clin Pharmacol** 1985 Apr; 7(4):179–81

Neurotensin stimulates polyphosphoinositide breakdown and prolactin release in anterior pituitary cells in culture. Canonico PL, et al. **Mol Cell Endocrinol** 1985 Oct;42(3):215–20

Has the prolactin inhibiting peptide at last been found? [news] Fink G. **Nature** 1985 Aug 8–14;316(6028):487–8

A prolactin-inhibiting factor within the precursor for human gonadotropin-releasing hormone. Nikolics K, et al. **Nature** 1985 Aug 8–14;316(6028):511–7

Immunocytochemical localization in rat brain of a prolactin release-inhibiting sequence of gonadotropin-releasing hormone prohormone. Phillips HS, et al. **Nature** 1985 Aug 8–14; 316(6028):542–5

Hormonal modulation of the responsiveness of midbrain central gray neurons to LH-RH. Chan A, et al. **Neuroendocrinology** 1985 Aug; 41(2):163–8

Effect of histamine on basal and TRH/LH-RH-stimulated PRL and LH secretion during different phases of the menstrual cycle in normal women. Knigge U, et al. **Neuroendocrinology** 1985 Oct;41(4):337–41

Effects of endogenous opioid peptides and opiates on luteinizing hormone and prolactin secretion in ovariectomized rats. Leadem CA, et al. **Neuroendocrinology** 1985 Oct;41(4):342–52

Progesterone and the control of functional luteolysis, of secretion of prolactin and of pituitary LHRH responsiveness. A study with pseudopregnant rats kept in alternating and constant lighting conditions. Schuiling GA, et al. **Neuroendocrinology** 1985 Jul;41(1):52–9

Pharmacological studies on the serotoninergic and nonserotonin-mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L–tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283–8

Electrical stimulation of the ventral noradrenergic tract (VNAT) releases hypothalamic noradrenaline and stimulates prolactin secretion in ovariectomized female rats treated with oestrogen. Dean AD, et al. **Neurosci Lett** 1985 Jun 4;57(1):73–8

A nonmitogenic pituitary function of fibroblast growth factor: regulation of thyrotropin and prolactin secretion. Baird A, et al. **Proc Natl Acad Sci USA** 1985 Aug;82(16):5545–9

Effect of various catecholamine antagonists on prolactin secretion in conscious male rabbits. Kaji H, et al. **Proc Soc Exp Biol Med** 1985 Oct;180(1):144–8

Thyrotropin–releasing hormone action: mechanism of calcium–mediated stimulation of prolactin secretion. Gershengorn MC. **Recent Prog Horm Res** 1985;41:607–53 (61 ref.)

Role of brain epinephrine neurons in the regulation of serum prolactin and luteinizing hormone release in female rats. Liang NY, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jun;48(3):459–62

Effects of pimozide and domperidone administration on prolactin levels in neonatally estrogenized female rats. Aguilar E, et al. **Rev Esp Fisiol** 1985 Jun;41(2):183–6

[Lack of effect of aging on dopaminergic inhibition of aldosterone and prolactin increase] Preis P, et al. **Z Gerontol** 1985 Jul–Aug; 18(4):241–3 (Eng. Abstr.) **(Ger)**

[Low blood values of prolactin in women with psychogenic amenorrhea and anorexia nervosa] Natoli A, et al. **Clin Ter** 1985 Jun 30; 113(6):499–501 (Eng. Abstr.) **(Ita)**

[Effect of dopaminergic agents on the endocrine profile in labor and early puerperium] Kubota T, et al. **Nippon Sanka Fujinka Gakkai Zasshi** 1985 Jun;37(6):945–54 (Eng. Abstr.) **(Jpn)**

PROMAZINE

Hemodynamic and acid–base effects of promazine on unanesthetized pregnant sheep and fetus. Ayromlooi J. **Dev Pharmacol Ther** 1985; 8(5):302–10

PROMETHAZINE

Effects of H1–receptor blocking drugs on the frog sartorius neuromuscular junction. Katayama S, et al. **Br J Pharmacol** 1985 Aug;85(4):747–53

Determination of promethazine in human plasma by automated high–performance liquid chromatography with electrochemical detection and by gas chromatography–mass spectrometry. Leelavathi DE, et al. **J Chromatogr** 1985 Apr 12;339(1):105–15

Degradation products of the promethazine radical cation. De Mol NJ, et al. **Pharm Weekbl [Sci]** 1985 Jun 21;7(3):121–4

Effect of promethazine and isosafrole on rat–hepatic microsomal mono–oxygenase activity: comparison with classic inducers phenobarbitone and beta–naphthoflavone. Taylor G, et al. **Xenobiotica** 1985 Mar;15(3):243–9

[Determination of aminophylline and promethazine in suppositories] Senf HJ. **Pharmazie** 1985 May;40(5):331–2 (Eng. Abstr.) **(Ger)**

[Effect of antidepressive drugs and histamine H1 receptor blockaders on histamine level in rat brain] Zawilska J, et al. **Folia Med Cracov** 1984; 25(3–4):297–306 (Eng. Abstr.) **(Pol)**

PROPANEDIOLS

Exhaustive laccase–catalysed oxidation of a lignin model compound (vanillyl glycol) produces methanol and polymeric quinoid products. Lundquist K, et al. **Biochem J** 1985 Jul 1;229(1):277–9

Pharmacokinetics of propylene glycol in humans during multiple dosing regimens. Yu DK, et al. **J Pharm Sci** 1985 Aug;74(8):876–9

The possible effect of high concentrations of propylene glycol on mitosis in human lymphocytes in vitro. Georgian L, et al. **Morphol Embryol (Bucur)** 1985 Jul–Sep;31(3):159–61

Propylene glycol plasma level [letter] Hall AH, et al. **Pediatrics** 1985 Oct;76(4):654

[Synthesis and analysis of glycol bis–phosphates, regulators of reversible hemoglobin oxygenation] Chuvilin AN, et al. **Bioorg Khim** 1985 Jun; 11(6):845–8 (Eng. Abstr.) **(Rus)**

PROPRANOLOL

Propranolol inhibits the maturational effect of adrenocorticotropin in the fetal sheep lung. Vilos GA, et al. **Am J Obstet Gynecol** 1985 Oct 15; 153(4):472–7

Effects of aspirin and propranolol on feline platelet aggregation. Greene CE. **Am J Vet Res** 1985 Sep;46(9):1820–3

Propranolol–induced hypertension in treatment of cocaine intoxication. Ramoska E, et al. **Ann Emerg Med** 1985 Nov;14(11):1112–3

Plasma protein binding of salicylic acid, phenytoin, chlorpromazine, propranolol and pethidine using equilibrium dialysis and ultracentrifugation. Verbeeck RK, et al. **Arzneimittelforschung** 1985; 35(6):903–6

Effect of plasma on human erythrocyte beta–adrenergic receptors. Sager G, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3767–71

Effect of propranolol on lecithin:cholesterol acyl transferase activity in vitro. Schauer UJ, et al. **Biomed Biochim Acta** 1985;44(4):603–9

The haemodynamic and myocardial contractile effects of celiprolol, atenolol and propranolol in mecamylamine–verapamil pretreated, anaesthetised dogs. Smith RD, et al. **Br J Clin Pract [Symp Suppl]** 1985 Jun;42:35–43

Increase in PaO2 following intravenous administration of propranolol in acutely hypoxemic patients. Vincent JL, et al. **Chest** 1985 Oct; 88(4):558–62

Sodium restriction amplifies and propranolol loading inhibits circadian rhythm of plasma renin–angiotensin and aldosterone. Cugini P, et al. **Chronobiologia** 1985 Apr–Jun;12(2):155–65

Propranolol's effect on phagocytizing ability of polymorphonuclears and monocytes [letter] Djaldetti M, et al. **Drug Intell Clin Pharm** 1985 Jul–Aug;19(7–8):583

Stereoselective sulfate conjugation of 4–hydroxypropranolol in vitro by different species. Christ DD, et al. **Drug Metab Dispos** 1985 May–Jun; 13(3):380–1

Stereochemistry of the in vivo disposition and metabolism of propranolol in dog and man using deuterium–labeled pseudoracemates. Walle T. **Drug Metab Dispos** 1985 May–Jun;13(3):279–82

Serum myoglobin concentrations are decreased by beta–adrenergic stimulation. Ljunghall S, et al. **Eur J Appl Physiol** 1985;54(1):54–7

A carrier–protein receptor is not a prerequisite for avid hepatic elimination of highly bound compounds: a study of propranolol elimination by the isolated perfused rat liver. Jones DB, et al. **Hepatology** 1985 Jul–Aug; 5(4):590–3

Plasma growth hormone responses to microinfusion of noradrenergic agents into or electrical stimulation of the hypothalamus and amygdala in baboons. McWilliam JR, et al. **Horm Metab Res** 1985 Sep; 17(9):443–7

The influence of reserpine and propranolol upon the IOP response to vanadate in the rabbit. Delamere NA, et al. **Invest Ophthalmol Vis Sci** 1985 Oct;26(10):1442–5

Effect of age on the hepatic clearance of propranolol in rats. Iwamoto K, et al. **J Pharm Pharmacol** 1985 Jul;37(7):466–70

Effect of vitamin K3 on the first–pass elimination of propranolol in the rat. Ishida R, et al. **J Pharm Sci** 1985 May;74(5):578–81

Reduced hepatic clearance of propranolol induced by chronic carbon tetrachloride treatment in rats. Iwamoto K, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):470–5

Effects of dimethylpropranolol (UM–272) on the electrophysiological properties of guinea–pig ventricular muscles. Kodama I, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):507–14

Site and mechanism of the centrally mediated hypotensive action of propranolol. Tackett RL, et al. **J Pharmacol Exp Ther** 1985 Oct; 235(1):66–70

A method for the assay of alpha 1–acid glycoprotein in dog serum and its application to the plasma binding of propranolol and oxprenolol in animals receiving rifampicin. Delcroix C, et al. **J Pharmacol Methods** 1984 Sep;12(2):97–105

Glucagon for propranolol overdose [letter] Smith RC, et al. **JAMA** 1985 Nov 1;254(17):2412

Effects of chronic beta–adrenergic blockade on hemodynamic and metabolic responses to endurance training. Lawlor MR, et al. **Med Sci Sports Exerc** 1985 Jun;17(3):393–400

Effect of beta–receptor blockade on anxiety with reference to the three–systems model of phobic behavior. Fagerström KO, et al. **Neuropsychobiology** 1985;13(4):187–93

Blockade of peripheral beta–adrenergic receptors fails to suppress the cerebral spread of an engram in mice. Church AC, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):27–31

Effect of propranolol on thyroid homeostasis of healthy volunteers. Wilkins MR, et al. **Postgrad Med J** 1985 May;61(715):391–4

Effects of d,l–propranolol on open field behavior of rats. Poli A, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):153–5

Opposing acute and chronic behavioural effects of a beta–blocker, propranolol, in the rat. Salmon P, et al. **Psychopharmacology (Berlin)** 1985;86(4):480–6

Comparison between the effects of propranolol and chlordiazepoxide on timing behaviour in the rat. Salmon P, et al.

Psychopharmacology (Berlin) 1985;87(2):219–24

Assessment of blood collection systems for the high performance liquid chromatography measurement of propranolol. Wong SH, et al. **Ther Drug Monit** 1985;7(3):358–63

[Cardiodynamics of the conscious dog undergoing treadmill exercise, blood pressure reduction or isoproterenol and its modification by beta-blockade] Lehmann HD. **DTW** 1985 Apr 9;92(4):135–9 (Eng. Abstr.) **(Ger)**

[The effect of propranolol on the pentetrazole-induced spindle activity in the EEG of the rat] Lasek R. **Pharmazie** 1985 May;40(5):364 **(Ger)**

[The anticonvulsant effect of propranolol in maximal electroshock in sub chronic applications] Lasek R. **Pharmazie** 1985 Jun;40(6):430 **(Ger)**

[A modified gas chromatographic method for the determination of propranolol in blood plasma] Stenzel WR, et al. **Pharmazie** 1985 May; 40(5):360–1 **(Ger)**

[Effect of propranolol on the vascular resistance of the human placenta perfused in vitro] Samberger M, et al. **Ginekol Pol** 1984 Dec; 55(12):895–900 (Eng. Abstr.) **(Pol)**

[Possibilities of using neurotropic agents for preventing the development of aphthous stomatitis] Airapetian GO, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):42–3 (Eng. Abstr.) **(Rus)**

[Prevention of the stress-induced decrease in natural killer activity by using a beta-adrenergic blocker and vitamin E] Meerson FZ, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):646–7 (Eng. Abstr.) **(Rus)**

[Thermoregulatory effect of beta-adrenoreceptor block in the cold-adapted rat at rest and during exertion] Divert VE, et al. **Fiziol Zh SSSR** 1985 Jun;71(6):777–81 (Eng. Abstr.) **(Rus)**

PROSTAGLANDINS

Prostaglandins enhance trigeminal substance P-ergic responses in the rabbit iris sphincter muscles. Ueda N, et al. **Brain Res** 1985 Jul 1; 337(2):347–51

Behavioral and neurochemical aspects of prostaglandins in brain function. Chiu EK, et al. **Gen Pharmacol** 1985;16(3):163–75 (115 ref.)

Evidence that the beta-adrenergic system and prostaglandins stimulate renin release through different mechanisms. Hsueh WA, et al. **J Clin Endocrinol Metab** 1985 Sep;61(3):399–403

Prostaglandin output from the early pregnant rat uterus superfused in vitro, and the effect of A23187 and trifluoperazine. Poyser NL. **J Reprod Fertil** 1985 May;74(1):271–7

Adrenergic stimulation modifies prostaglandin synthesis by rat vas deferens. Peredo H, et al. **Prostaglandins Leukotrienes Med** 1985 Jul; 19(1):51–61

[Role of the kallikrein-kinin system and prostaglandins in the action of dopamine on blood flow and sodium transport in the rat kidney] Kuz'min OB, et al. **Fiziol Zh SSSR** 1985 May;71(5):619–24 (Eng. Abstr.) **(Rus)**

PSILOCYBINE

Mushroom use by college students. Thompson JP, et al. **J Drug Educ** 1985;15(2):111–24

PSYCHIATRIC STATUS RATING SCALES

Profiles of antidepressant activity with the Montgomery-Asberg Depression Rating Scale. Montgomery SA, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:38–42

The clinical interview for depression. Development, reliability and validity. Paykel ES. **J Affective Disord** 1985 Jul;9(1):85–96

PSYCHIATRY

Cultural phenomenology and residency training revisited: a personal account. Zimmer B. **Int J Soc Psychiatry** 1985 Autumn;31(3):188–93

PSYCHOMOTOR PERFORMANCE

Task-dependent development of cross-tolerance to psychomotor effects of lorazepam in man. Aranko K. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):373–81

Psychomotor effects of alprazolam and diazepam during acute and subacute treatment, and during the follow-up phase. Aranko K, et al. **Acta Pharmacol Toxicol (Copenh)** 1985 May;56(5):364–72

Central effects during the continuous osmotic infusion of a benzodiazepine (triazolam). Breimer DD, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):807–15

A conveyor belt task for assessing visuo-motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d-amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):125–31

[Pharmacology in automobile driving and medical practice. II. Euhypnotic effect of Elenium and psychomotor efficiency in humans] Galuszko P, et al. **Psychiatr Pol** 1984 Nov–Dec;18(6):555–60 (Eng. Abstr.) **(Pol)**

PSYCHOPHARMACOLOGY

Comparison of fixed-ratio and progressive-ratio schedules of maintenance of stimulant drug-reinforced responding. Winger G, et al. **Drug Alcohol Depend** 1985 May;15(1–2):123–30

A conveyor belt task for assessing visuo-motor coordination in the marmoset (Callithrix jacchus): effects of diazepam, chlorpromazine, pentobarbital and d-amphetamine. D'Mello GD, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):125–31

Drug discrimination training with a single choice trial per session. Tomie A, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):217–22

[A simply designed apparatus and its use for measuring vertical and horizontal motor activities in methamphetamine-treated mice] Itoh T, et al. **Yakubutsu Seishin Kodo** 1985 May;5(1):19–23 (Eng. Abstr.) **(Jpn)**

PSYCHOPHYSIOLOGIC DISORDERS

Clonidine treatment in vegetative dysfunction—experimental rationales. Svensson TH. **Acta Obstet Gynecol Scand [Suppl]** 1985;132:23–8

Experimental comparison of low doses of 1.5 mg fluspirilene and bromazepam in out-patients with psychovegetative disturbances. Hassel P. **Pharmacopsychiatry** 1985 Sep;18(5):297–302

[Low blood values of prolactin in women with psychogenic amenorrhea and anorexia nervosa] Natoli A, et al. **Clin Ter** 1985 Jun 30; 113(6):499–501 (Eng. Abstr.) **(Ita)**

PSYCHOSES, SUBSTANCE-INDUCED

Lorazepam dependence and chronic psychosis [letter] Fraser AA, et al. **Br J Psychiatry** 1985 Aug;147:211

PSYCHOSEXUAL DISORDERS

Erotomania in Schneider-positive schizophrenia. A case report. Hayes M, et al. **Br J Psychiatry** 1985 Jun;146:661–3

PSYCHOTHERAPY

Maintenance treatment of recurrent unipolar depression: pharmacology and psychotherapy. Frank E, et al. **Adv Biochem Psychopharmacol** 1985; 40:139–51

Patterns of attrition for psychosocial and pharmacologic treatments of depression. Last CG, et al. **J Clin Psychiatry** 1985 Sep;46(9):361–6

Carbamazepine and psychotherapy in the treatment of schizoaffective psychosis. Cegalis JA, et al. **Yale J Biol Med** 1985 Jul–Aug; 58(4):327–36

[Witchcraft: parallel practice] Glachant A. **Soins Psychiatr** 1985 May; (55):10–2 **(Fre)**

PSYCHOTHERAPY, GROUP

[Value of group psychotherapy in the after care of schizophrenic patients. A 5 year follow-up study] Hartwich P, et al. **Nervenarzt** 1985 Jul; 56(7):365–72 **(Ger)**

PSYCHOTIC DISORDERS

Chronic treatments in neuropsychiatry. **Adv Biochem Psychopharmacol** 1985;40:1–219

Response to lithium prophylaxis in schizoaffective psychoses. Kemali D, et al. **Adv Biochem Psychopharmacol** 1985;40:153–8

An open clinical trial of carbamazepine in treatment-resistant bipolar and schizo-affective psychotics. Elphick M. **Br J Psychiatry** 1985 Aug; 147:198–200

Early clinical experiences with sulpiride [letter] Soni SD, et al. **Br J Psychiatry** 1985 Jun;146:673

Assessment and treatment of the late-onset psychoses. Leuchter AF. **Hosp Community Psychiatry** 1985 Aug;36(8):815–6, 818

Slow-release lithium in treatment of schizoaffective syndromes. Romeo R, et al. **Int J Clin Pharmacol Res** 1985;5(3):205–11

Lithium dosage in the elderly. A study with matched age groups. Greil W, et al. **J Affective Disord** 1985 Jul;9(1):1–4

Pharmacology of neuroleptics in use in the United States. Richelson E. **J Clin Psychiatry** 1985 Aug;46(8 Pt 2):8–14

The late-onset psychoses. Clinical and diagnostic features. Leuchter AF, et al. **J Nerv Ment Dis** 1985 Aug;173(8):488–94

Early relapse after sudden withdrawal or dose reduction of clozapine [letter] Perényi A, et al. **Psychopharmacology (Berlin)** 1985; 86(1–2):244

Comparative efficacy of red cell and plasma haloperidol as predictors of clinical response in schizophrenia. Smith RC, et al. **Psychopharmacology (Berlin)** 1985;85(4):449–55

Carbamazepine and psychotherapy in the treatment of schizoaffective psychosis. Cegalis JA, et al. **Yale J Biol Med** 1985 Jul–Aug; 58(4):327–36

[Witchcraft: parallel practice] Glachant A. **Soins Psychiatr** 1985 May; (55):10–2 **(Fre)**

[Report of a patient thought to have a reactive psychosis] Borišev L. **Med Pregl** 1985;38(5-6):265-7 (Eng. Abstr.) **(Scr)**

[Evaluation of the efficacy of haloperidol decanoate in the treatment of chronic psychotic hospital patients] Marchant N, et al. **Acta Psiquiatr Psicol Am Lat** 1985 Mar;31(1):37-41 (Eng. Abstr.) **(Spa)**

QUINIDINE

Digoxin interactions. The influence of quinidine and verapamil on the pharmacokinetics and receptor binding of digitalis glycosides. Pedersen KE. **Acta Med Scand [Suppl]** 1985;697:1-40

Correlation of a quinidine-induced platelet-specific antibody with development of thrombocytopenia. Garty M, et al. **Am J Med** 1985 Aug;79(2):253-5

Inhibition of Ca2+-activated K+ channels in pig pancreatic acinar cells by Ba2+, Ca2+, quinine and quinidine. Iwatsuki N, et al. **Biochim Biophys Acta** 1985 Oct 10;819(2):249-57

Liquid chromatographic determination of quinine, hydroquinine, saccharin, and sodium benzoate in quinine beverages. Valenti LP. **J Assoc Off Anal Chem** 1985 Jul-Aug;68(4):782-4

Interrelationships among quinidine, amiloride, and lithium as inhibitors of the renal Na+-H+ exchanger. Mahnensmith RL, et al. **J Biol Chem** 1985 Oct 15;260(23):12586-92

The influence of chemical agents on the level of ionized [Ca2+] in squid axons. Requena J, et al. **J Gen Physiol** 1985 Jun;85(6):789-804

Digoxin quinidine interaction: a pharmacokinetic study in the isolated perfused rat liver. Ben-Itzhak J, et al. **Life Sci** 1985 Aug 5; 37(5):411-5

Specific immunoassays for quinine and quinidine: comparison of radioimmunoassay and enzyme-linked immunosorbent assay procedures. Morgan MR, et al. **Planta Med** 1985 Jun;(3):237-41

Kinetics of microsomal metabolism of quinidine in rats. Rakhit A, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jul;49(1):109-24

REACTION TIME

Temazepam and the perceptual-motor performance of professional footballers. Golby J, et al. **Br J Sports Med** 1985 Jun;19(2):115-8

Effects of diazepam and triazolam on auditory and visual thresholds and reaction times in the baboon. Lukas SE, et al. **Psychopharmacology (Berlin)** 1985;87(2):167-72

RECEPTORS, ADRENERGIC

Postsynaptic alpha 2-noradrenergic receptors mediate feeding induced by paraventricular nucleus injection of norepinephrine and clonidine. Goldman CK, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):11-9

Autoregulation of endogenous epinephrine release via presynaptic adrenoceptors in the rat hypothalamic slice. Goshima Y, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):248-53

Role of adenosine 3',5'-cyclic monophosphate in adrenoceptor-mediated control of 3H-noradrenaline secretion in guinea-pig ileum myenteric nerve terminals. Alberts P, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):114-20

Neurochemical studies on GABAergic and aminergic systems in the rat brain following acute and chronic piracetam administration. Masotto C, et al. **Pharmacol Res Commun** 1985 Aug;17(8):749-72

Adrenergic stimulation modifies prostaglandin synthesis by rat vas deferens. Peredo H, et al. **Prostaglandins Leukotrienes Med** 1985 Jul; 19(1):51-61

[Catecholaminergic receptors of the blood cells of schizophrenics] Ackenheil M, et al. **Encephale** 1985 May-Jun;11(3):95-100 (Eng. Abstr.) **(Fre)**

[Monoaminergic structures of the hypothalamus in chronic stress] Konstantinova MS, et al. **Probl Endokrinol (Mosk)** 1985 Jul-Aug; 31(4):49-51 (Eng. Abstr.) **(Rus)**

RECEPTORS, ADRENERGIC, ALPHA

Adrenoreceptor interactions of the enantiomers and metabolites of mianserin: are they responsible for the antidepressant effect? Pinder RM. **Acta Psychiatr Scand [Suppl]** 1985;320:1-9 (29 ref.)

Arylazide photoaffinity probe for alpha 2-adrenoceptors. Regan JW, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3667-72

The effects of phenoxybenzamine on specific binding and function of central alpha-adrenoceptors in the rabbit. Hamilton CA, et al. **Brain Res** 1985 Sep 30;344(1):89-95

Regulation of central alpha-adrenoceptors by serotoninergic denervation. Rappaport A, et al. **Brain Res** 1985 Sep 30;344(1):158-61

Renal nerve stimulation causes alpha 1-adrenoceptor-mediated sodium retention but not alpha 2-adrenoceptor antagonism of vasopressin. Smyth DD, et al. **Circ Res** 1985 Aug;57(2):304-11

Neuronally released norepinephrine does not preferentially activate postjunctional alpha 1-adrenoceptors in human blood vessels in vitro. Stevens MJ, et al. **Circ Res** 1985 Sep;57(3):399-405

Electrophysiological and receptor studies in rat brain: effects of clorgyline. Campbell IC, et al. **Eur J Pharmacol** 1985 May 20;111(3):355-64

Postsynaptic alpha 2-noradrenergic receptors mediate feeding induced by paraventricular nucleus injection of norepinephrine and clonidine. Goldman CK, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):11-9

The importance of the alpha-adrenoceptor agonist activity of dobutamine to inotropic selectivity in the anaesthetized cat. Kenakin TP, et al. **Eur J Pharmacol** 1985 May 20;111(3):347-54

Chronic clonidine induces functional down-regulation of presynaptic alpha 2-adrenoceptors regulating [3H]noradrenaline and [3H]5-hydroxytryptamine release in the rat brain. Maura G, et al. **Eur J Pharmacol** 1985 May 28;112(1):105-10

Chronic haloperidol causes increase in salivary response and alpha 1-adrenoceptors in submandibular gland of the rat. Pazo JH, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):121-4

Relationship between alpha 2-adrenoceptor occupancy and response for B-HT 933 in canine saphenous vein. Ruffolo RR Jr, et al. **Eur J Pharmacol** 1985 May 8;111(2):267-71

Permissive role of spinal alpha 1-adrenoceptors in sudomotor efferents. Rybarczyk MC, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):339-48

Effects of iminodibenzyl antipsychotic drugs on cerebral dopamine and alpha-adrenergic receptors. Setoguchi M, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):313-22

Effect of phenoxybenzamine and clonidine on the adrenergic receptor in the rat brain; histofluorescence and ultrastructure examinations. Wawrzyniak M, et al. **Folia Histochem Cytobiol** 1985;23(1-2):91-2

Association of the changes in cytosolic Ca2+ and iodide efflux induced by thyrotropin and by the stimulation of alpha 1-adrenergic receptors in cultured rat thyroid cells. Corda D, et al. **J Biol Chem** 1985 Aug 5;260(16):9230-6

Characterization of alpha 2-adrenoceptor binding properties of imidazoline-like drugs, azoloazepine derivatives and beta-phenethylamine-like drugs in human platelet membranes. Vago T, et al. **J Pharm Pharmacol** 1985 Aug;37(8):593-6

Nimodipine and inhibition of alpha adrenergic activation of the isolated canine saphenous vein. Cooke JP, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):598-602

Effect of imipramine and adrenocorticotropin administration on the rat brain norepinephrine-coupled cyclic nucleotide generating system: alterations in alpha and beta adrenergic components. Duman RS, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):409-14

Synergistic interaction between alpha- and beta-adrenergic receptors in rat brain slices: possible site for antidepressant drug action. Pilc A, et al. **Life Sci** 1985 Sep 30;37(13):1183-94

The relationships between receptor binding capacity for norepinephrine, angiotensin II, and vasopressin and release of inositol trisphosphate, Ca2+ mobilization, and phosphorylase activation in rat liver. Lynch CJ, et al. **Mol Pharmacol** 1985 Aug;28(2):93-9

Dopaminergic modulation of hippocampal noradrenaline release. Evidence for alpha 2-antagonistic effects of some dopamine receptor agonists and antagonists. Jackisch R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):105-13

Disturbances of norepinephrine metabolism and alpha-2 adrenergic receptor activity in anorexia nervosa: relationship to nutritional state. Kaye WH, et al. **Psychopharmacol Bull** 1985;21(3):419-23

RECEPTORS, ADRENERGIC, BETA

Beta receptors in peripheral mononuclear cells increase acutely during exercise. Burman KD, et al. **Acta Endocrinol (Copenh)** 1985 Aug; 109(4):563-8

Influence of beta-receptor stimulation on catecholamine and phospholipid concentrations in lungs of fetal rabbits. Urban J, et al. **Acta Paediatr Hung** 1985;26(2):127-32

Participation of the beta-adrenergic receptor in the enteroruminal reflex and enteroenteric reflex. Wegrzyn T, et al. **Acta Physiol Pol** 1984 May-Jun;35(3):193-8

Effect of GRP on beta-adrenergic-stimulated gastrin and somatostatin release in the isolated rat stomach. Short GM, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):G197-202

Effect of plasma on human erythrocyte beta-adrenergic receptors. Sager G, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3767-71

Desensitization of beta-receptors on primary astrocyte cultures by norepinephrine but not by tricyclic antidepressants. Frangakis MV, et al. **Brain Res** 1985 Jul 22;339(1):49-56

Primary cultures from defined brain areas; effects of seeding time on the development of beta-adrenergic- and dopamine-stimulated cAMP-activity during cultivation. Hansson E. **Brain Res** 1985 Aug; 353(2):187-92

Beta-adrenergic binding and secretory responses of the anterior pituitary. Perkins SN, et al. **Endocrinology** 1985 Nov;117(5):1818-25

Trimipramine, a tricyclic antidepressant exerting atypical actions on the central noradrenergic system. Hauser K, et al. **Eur J Pharmacol** 1985 Apr 23;111(1):23-30

Evidence that the beta-adrenergic system and prostaglandins stimulate renin release through different mechanisms. Hsueh WA, et al. **J Clin Endocrinol Metab** 1985 Sep;61(3):399-403

The affinity and efficacy of naturally occurring catecholamines at beta-adrenoceptor subtypes. McPherson GA, et al. **J Pharm Pharmacol** 1985 Jul;37(7):499-501

Effect of imipramine and adrenocorticotropin administration on the rat brain norepinephrine-coupled cyclic nucleotide generating system: alterations in alpha and beta adrenergic components. Duman RS, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):409-14

Rapid down regulation of beta adrenergic receptors by combining antidepressant drugs with forced swim: a model of antidepressant-induced neural adaptation. Duncan GE, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):402-8

Synergistic interaction between alpha- and beta-adrenergic receptors in rat brain slices: possible site for antidepressant drug action. Pilc A, et al. **Life Sci** 1985 Sep 30;37(13):1183-94

Behavioral evidence for beta-adrenoceptor subsensitivity after subacute antidepressant/alpha 2-adrenoceptor antagonist treatment. Goldstein JM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun; 329(4):355-8

Blockade of peripheral beta-adrenergic receptors fails to suppress the cerebral spread of an engram in mice. Church AC, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):27-31

Studies of beta-adrenergic receptors in leukocytes of patients with affective illness and effects of antidepressant drugs. Pandey GN, et al. **Psychopharmacol Bull** 1985;21(3):603-5

The serotonin/norepinephrine-linked beta-adrenoceptor system and the mode of action of antidepressants. Sanders-Bush E, et al. **Psychopharmacol Bull** 1985;21(3):373-8

A strong influence of serotonin axons on beta-adrenergic receptors in rat brain. Stockmeier CA, et al. **Science** 1985 Oct 18; 230(4723):323-5

[Thermoregulatory effect of beta-adrenoreceptor block in the cold-adapted rat at rest and during exertion] Divert VE, et al. **Fiziol Zh SSSR** 1985 Jun;71(6):777-81 (Eng. Abstr.) **(Rus)**

RECEPTORS, CHOLINERGIC

Open channel noise. I. Noise in acetylcholine receptor currents suggests conformational fluctuations. Sigworth FJ. **Biophys J** 1985 May; 47(5):709-20

Histamine is an antagonist of the acetylcholine receptor at the frog endplate. Ariyoshi M, et al. **Br J Pharmacol** 1985 May;85(1):65-73

Enthalpy-entropy relationship in drug-cholinoceptor interaction: a new approach. Cohen S, et al. **Br J Pharmacol** 1985 Aug;85(4):889-96

Interactions of edrophonium, physostigmine and methanesulfonyl fluoride with the snake end-plate acetylcholine receptor-channel complex. Fiekers JF. **J Pharmacol Exp Ther** 1985 Sep;234(3):539-49

Acetylcholine- and 5-hydroxytryptamine-stimulated contraction and calcium uptake in bovine coronary arteries: evidence for two populations of receptor-operated calcium channels. Ratz PH, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):641-7

Rapid induction of supersensitivity to muscarinic antagonists-induced motor excitation by continuous stimulation of cholinergic receptors. Fernando JC, et al. **Life Sci** 1985 Sep 2;37(9):883-92

Reduced muscarinic receptor plasticity in frontal cortex of aged rats after chronic administration of cholinergic drugs. Pedigo NW Jr, et al. **Life Sci** 1985 Oct 14;37(15):1443-9

RECEPTORS, DOPAMINE

Blockade of renal effects of dopamine in the dog by the DA1 antagonist SCH 23390. Frederickson ED, et al. **Am J Physiol** 1985 Aug; 249(2 Pt 2):F236-40

Evidence for cholecystokinin-dopamine receptor interactions in the central nervous system of the adult and old rat. Studies on their functional meaning. Agnati LF, et al. **Ann NY Acad Sci** 1985; 448:315-33

Cholecystokinin neuron systems and their interactions with the presynaptic features of the dopamine neuron systems. A morphometric and neurochemical analysis involving studies on the action of cholecystokinin-8 and cholecystokinin-58. Fuxe K, et al. **Ann NY Acad Sci** 1985;448:231-54

Electrophysiological studies of the role of cholecystokinin in the substantia nigra and its interactions with dopamine. Skirboll LR, et al. **Ann NY Acad Sci** 1985;448:275-82

Distinct properties of cholecystokinin-8 and mixed dopamine-cholecystokinin-8 neurons innervating the nucleus accumbens. Studler JM, et al. **Ann NY Acad Sci** 1985;448:306-14

Photoaffinity labeling of D-2 dopamine binding subunits from rat striatum, anterior pituitary and olfactory bulb with a new probe, [3H]azidosulpride. Redouane K, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1086-92

Effects of heavy metal cations, sulfhydryl reagents and other chemical agents on striatal D2 dopamine receptors. Scheuhammer AM, et al. **Biochem Pharmacol** 1985 Oct 1;34(19):3405-13

Partial purification of dopamine D2 receptors using lectin affinity columns. Abbott WM, et al. **Biosci Rep** 1985 Apr;5(4):303-8

Selective effects of thiol reagents on the binding sites for imipramine and neurotransmitter amines in the rat brain. Biassoni R, et al. **Br J Pharmacol** 1985 Jun;85(2):447-56

Vasomotor responses of cerebral arterioles in situ to putative dopamine receptor agonists. Edvinsson L, et al. **Br J Pharmacol** 1985 Jun; 85(2):403-10

Dopamine D-2 receptors in rat caudate-putamen: the lateral to medial gradient does not correspond to dopaminergic innervation. Joyce JN, et al. **Brain Res** 1985 Jul 15;338(2):209-18

In vivo voltammetric and behavioural evidence for somatodendritic autoreceptor control of mesolimbic dopamine neurones. Maidment NT, et al. **Brain Res** 1985 Jul 15;338(2):317-25

SCH 23390, a selective D1 dopamine receptor blocker, enhances the firing rate of nigral dopaminergic neurons but fails to activate striatal tyrosine hydroxylase. Onali P, et al. **Brain Res** 1985 Aug 5;340(1):1-7

The functional state of the dopamine receptor in the anterior pituitary is in the high affinity form. George SR, et al. **Endocrinology** 1985 Aug; 117(2):690-7

Interaction of SCH 23390, a D-1-selective antagonist, with the anterior pituitary D-2 receptors and prolactin secretion in the rat. Apud JA, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):187-93

SCH-23390 antagonism of a D-2 dopamine agonist depends upon catecholaminergic neurons. Breese GR, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):109-14

DSP-4 lesioning prevents the enhancement of dopamine and 5-hydroxytryptamine mediated behavioural changes by repeated electroconvulsive shock. Heal DJ, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):117-21

Presynaptic dopamine and serotonin receptors modulating tyrosine hydroxylase activity in synaptosomes of the nucleus accumbens of rats. Hetey L, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):1-10

Effect of transition or heavy metals on [3H]haloperidol binding in rat striatal membranes in vitro. Komulainen H, et al. **Eur J Pharmacol** 1985 Aug 15;114(2):113-9

SCH 23390, a selective dopamine D1 antagonist, activates dopamine neurons but fails to prevent their inhibition by apomorphine. Mereu G, et al. **Eur J Pharmacol** 1985 May 20;111(3):393-6

Striatal dopamine receptor sensitivity after subchronic fencamfamine in the rat. Scavone C, et al. **Eur J Pharmacol** 1985 May 28; 112(1):11-6

Lack of evidence supporting a role for dopamine in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine neurotoxicity. Schmidt CJ, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):149-50

Effects of iminodibenzyl antipsychotic drugs on cerebral dopamine and alpha-adrenergic receptors. Setoguchi M, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):313-22

Progabide reverses the nigral substance P reduction induced by chronic impairment of dopaminergic transmission. Zivkovic B, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):253-5

Behavioral and eegraphic changes induced by dopaminergic antidepressants in rabbits. Bo P, et al. **Farmaco [Sci]** 1985 Aug; 40(8):608-16

Effects of phospholipids on the specific binding of [3H]spiroperidol to the cholate extract of rat brain synaptic membranes. Moroi K, et al. **Int J Biochem** 1985;17(5):637-44

Novel dopamine receptor agonists and antagonists with preferential action on autoreceptors. Johansson AM, et al. **J Med Chem** 1985 Aug; 28(8):1049-53

Dopamine-receptor agonists: mechanisms underlying autoreceptor selectivity. I. Review of the evidence. Clark D, et al. **J Neural Transm** 1985;62(1-2):1-52 (168 ref.)

Dopamine receptor agonists: mechanisms underlying autoreceptor selectivity. II. Theoretical considerations. Clark D, et al. **J Neural Transm** 1985;62(3-4):171-207 (69 ref.)

[3H]205-501, a non-catechol dopaminergic agonist, labels selectively and with high affinity dopamine D2 receptors. Closse A, et al. **J Neural Transm** 1985;62(3-4):231-48

Development of dopamine autoreceptors in the postnatal rat brain. Hedner T, et al. **J Neural Transm** 1985;62(1-2):53-63

Hypothesis: bromocriptine lacks intrinsic dopamine receptor stimulating properties. Jackson DM, et al. **J Neural Transm** 1985;62(3-4):219-30 (31 ref.)

Mesolimbic dopamine function is not altered during continuous chronic treatment of rats with typical or atypical neuroleptic drugs. Rupniak NM, et al. **J Neural Transm** 1985;62(3-4):249-66

Effect of iron chelators on dopamine D2 receptors. Ben-Shachar D, et al. **J Neurochem** 1985 Oct;45(4):999-1005

D2 dopamine receptors in calf globus pallidus: agonist high- and low-affinity sites not regulated by guanine nucleotide. De Keyser J, et al. **J Neurochem** 1985 Sep;45(3):977-9

Binding of [3H]SCH23390 in rat brain: regional distribution and effects of assay conditions and GTP suggest interactions at a D1-like dopamine receptor. Schulz DW, et al. **J Neurochem** 1985 Nov;45(5):1601-11

Properties of rat striatal D-2 dopamine receptors solubilized with the zwitterionic detergent CHAPS. Kilpatrick GJ, et al. **J Pharm Pharmacol** 1985 May;37(5):320-8

Cis- and trans-4-n-Propyl-1,2,3,4,4a,5,6,10b-octahydrobenzo(*f*)quinolines.

Cannon JG, et al. **J Pharm Sci** 1985 Jun;74(6):672–5

Dopamine agonist–induced locomotor activity in rats treated with 6–hydroxydopamine at differing ages: functional supersensitivity of D–1 dopamine receptors in neonatally lesioned rats. Breese GR, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):447–55

Pharmacological analysis of the actions of SKF 82526 on cardiovascular dopamine receptors. Lokhandwala MF, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):337–44

Simple method for evaluation of stimulatory effect of drugs on presynaptic dopamine receptors in mice. Watanabe H. **J Pharmacol Methods** 1985 Aug;14(1):41–7

Hyperactivity induced by stimulation of separate dopamine D–1 and D–2 receptors in rats with bilateral 6–OHDA lesions. Arnt J. **Life Sci** 1985 Aug 26;37(8):717–23

Effects of isomers of apomorphines on dopamine receptors in striatal and limbic tissue of rat brain. Kula NS, et al. **Life Sci** 1985 Sep 16; 37(11):1051–7

Dopamine D–2 receptor–mediated excitation of caudate nucleus neurons from the substantia nigra. Ohno Y, et al. **Life Sci** 1985 Oct 21; 37(16):1515–21

Characterization of dopamine receptors mediating inhibition of adenylate cyclase activity in rat striatum. Onali P, et al. **Mol Pharmacol** 1985 Aug;28(2):138–45

Antistereotypic effects of dopamine D–1 and D–2 antagonists after intrastriatal injection in rats. Pharmacological and regional specificity. Arnt J. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug; 330(2):97–104

Dopaminergic modulation of hippocampal noradrenaline release. Evidence for alpha 2–antagonistic effects of some dopamine receptor agonists and antagonists. Jackisch R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):105–13

Dopamine D2 receptors selectively labeled by a benzamide neuroleptic: [3H]–YM–09151–2. Niznik HB, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):333–43

S(+)Apomorphines. Selective inhibition of excitatory effects of dopamine injected into the limbic system of the rat. Campbell A, et al. **Neuropharmacology** 1985 May;24(5):391–9

Effects on the caudate spindle in rats of dopamine microinjected into the caudate nucleus. Okuyama S, et al. **Neurosci Lett** 1985 Aug 16; 59(1):27–32

Mesolimbic and striatal dopamine receptor supersensitivity: prophylactic and reversal effects of L–prolyl–L–leucyl–glycinamide (PLG). Chiu P, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):179–83

Reduced head–twitch response to quipazine of rats previously treated with methiothepin: possible involvement of dopaminergic system. Dall'Olio R, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):43–8

Lidocaine kindling is accompanied by an increase in apomorphine stereotypy and mesolimbic dopamine D2 receptor density. Csernansky JG, et al. **Psychopharmacol Bull** 1985;21(3):707–11

The window of vulnerability in the ontogeny of the dopamine receptor. Miller JC, et al. **Psychopharmacol Bull** 1985;21(3):683–5

Dopamine receptor binding of C–11–3–N–methylspiperone in the caudate in schizophrenia and bipolar disorder: a preliminary report. Wong DF, et al. **Psychopharmacol Bull** 1985;21(3):595–8

Cocaine: excitatory effects on sensorimotor reactivity measured with acoustic startle. Davis M. **Psychopharmacology (Berlin)** 1985; 86(1–2):31–6

Effects of discontinuous drug administration on the development of dopamine receptor supersensitivity during chronic trifluoperazine or cis–flupenthixol administration to rats. Murugaiah K, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):228–32

The comparative long–term effects of ciladopa (AY–27,110), a chemically novel dopaminergic agonist, in 6–OHDA–lesioned and intact rats. Voith K. **Psychopharmacology (Berlin)** 1985;85(4):405–9

Progesterone action on the LHRH and the nigrostriatal dopamine neuronal systems: in vitro and in vivo studies. Ramirez VD, et al. **Recent Prog Horm Res** 1985;41:421–72 (110 ref.)

[Effect of l–stepholidine on rotational behavior in rats] Shi WX, et al. **Chung Kuo Yao Li Hsueh Pao** 1984 Dec;5(4):222–5 (Eng. Abstr.) **(Chi)**

[Effect of arachidonic acid on stereotyped behavior in the rabbit induced by a dopamine receptor agonist] Kurchikov AL, et al. **Zh Vyssh Nerv Deiat** 1985 Jul–Aug;35(4):783–5 **(Rus)**

RECEPTORS, DRUG

Digoxin interactions. The influence of quinidine and verapamil on the pharmacokinetics and receptor binding of digitalis glycosides. Pedersen KE. **Acta Med Scand [Suppl]** 1985;697:1–40

In situ molecular weight determination of rat brain [3H]phenytoin binding sites. Spero L. **Can J Physiol Pharmacol** 1985 May;63(5):515–6

A common single binding site for many psychotropic drugs on human alpha 1–acid glycoprotein. Therapeutically relevant observation? Müller WE. **Pharmacopsychiatry** 1985 Jul;18(4):257–8

RECEPTORS, ENDOGENOUS SUBSTANCES

Somatostatin agonists and antagonists—peptide control of growth hormone secretion. Coy DH, et al. **Adv Exp Med Biol** 1985; 188:325–37

Mechanisms of somatostatin action in pituitary cells. Schonbrunn A, et al. **Adv Exp Med Biol** 1985;188:305–24

Somatostatin receptors. Srikant CB, et al. **Adv Exp Med Biol** 1985; 188:291–304

Cholecystokinin and cultured spinal neurons. Immunohistochemistry, receptor binding, and neurophysiology. Rogawski MA, et al. **Ann NY Acad Sci** 1985;448:403–12

Receptors and phosphoinositide–generated second messengers. Hokin LE. **Annu Rev Biochem** 1985;54:205–35 (351 ref.)

Protein–tyrosine kinases. Hunter T, et al. **Annu Rev Biochem** 1985; 54:897–930 (239 ref.)

Thyroid–dependent maturation of neonatal brain but not lung epidermal growth factor receptors. Sadiq HF, et al. **Dev Pharmacol Ther** 1985; 8(5):292–301

Hyperprolactinemia inhibits gonadotropin–releasing hormone (GnRH) stimulation of the number of pituitary GnRH receptors. Garcia A, et al. **Endocrinology** 1985 Sep;117(3):954–9

Photoaffinity labeling of pituitary and gonadal receptors for gonadotropin–releasing hormone. Iwashita M, et al. **Endocrinology** 1985 Aug;117(2):738–46

Modulation of somatostatin binding to rat pituitary membranes by exogenously administered growth hormone. Katakami H, et al. **Endocrinology** 1985 Aug;117(2):557–60

Structural requirements for the activation of rat anterior pituitary adenylate cyclase by growth hormone–releasing factor (GRF): discovery of (N–Ac–Tyr1, D–Arg2)–GRF(1–29)–NH2 as a GRF antagonist on membranes. Robberecht P, et al. **Endocrinology** 1985 Nov; 117(5):1759–64

Chronic carbamazepine treatment increases brain adenosine receptors. Marangos PJ, et al. **Epilepsia** 1985 Sep–Oct;26(5):493–8

A carrier–protein receptor is not a prerequisite for avid hepatic elimination of highly bound compounds: a study of propranolol elimination by the isolated perfused rat liver. Jones DB, et al. **Hepatology** 1985 Jul–Aug; 5(4):590–3

Inhibition of fibrinogen receptor expression and serotonin release by leupeptin and antipain. Baldassare JJ, et al. **J Biol Chem** 1985 Sep 5; 260(19):10531–5

Pituitary receptors for LH–releasing hormone (LHRH) and responsiveness to LHRH in adult female rats after neonatal monosodium L–glutamate treatment. Inkster SE, et al. **J Endocrinol** 1985 Oct; 107(1):9–13

Pituitary gonadotrophin–releasing hormone receptor up–regulation in vitro: dependence on calcium and microtubule function. Young LS, et al. **J Endocrinol** 1985 Oct;107(1):49–56

Thyrotropin–releasing hormone receptor binding sites: autoradiographic distribution in the rat and guinea pig brain. Pazos A, et al. **J Neurochem** 1985 Nov;45(5):1448–63

Role of GnRH in the regulation of pituitary GnRH receptors in female mice. Naik SI, et al. **J Reprod Fertil** 1985 Jul;74(2):605–14

Evidence for a pituitary site of gonadal steroid stimulation of GnRH receptors in female mice. Naik SI, et al. **J Reprod Fertil** 1985 Jul; 74(2):615–24

The mechanisms of LHRH agonist action in gonadal tissues. Cooke BA, et al. **Mol Cell Endocrinol** 1985 Jul;41(2–3):115–22 (68 ref.)

The relationships between receptor binding capacity for norepinephrine, angiotensin II, and vasopressin and release of inositol trisphosphate, Ca2+ mobilization, and phosphorylase activation in rat liver. Lynch CJ, et al. **Mol Pharmacol** 1985 Aug;28(2):93–9

Ovarian LHRH receptors increase following lesions of the major LHRH structures in the rat brain: involvement of a direct neural pathway. Marchetti B, et al. **Neuroendocrinology** 1985 Oct;41(4):321–31

Estradiol–induced LH release in juvenile female rats: nembutal blocks both the decline and the exposure of nonavailable pituitary LHRH receptor sites. Smith SS, et al. **Neuroendocrinology** 1985 Sep; 41(3):246–51

Effects of transition metals on TRH–receptor interaction. Ogawa N, et al. **Neurosci Res** 1984 Oct;1(5):363–8

Peripheral models for the study of neurotransmitter receptors in man. Stahl SM. **Psychopharmacol Bull** 1985;21(3):663–71

[Age aspects of receptor–effector reactions and the regulation of adenylate cyclase activity] Burchinskii SG, et al. **Ukr Biokhim Zh** 1985 Jul–Aug; 57(4):86–98 (101 ref.) (Eng. Abstr.) **(Rus)**

RECEPTORS, ENDORPHIN

Quantitative localization of [3H]TCP binding in rat brain by light microscopy autoradiography. Sircar R, et al. **Brain Res** 1985 Sep 30; 344(1):142–5

Evidence that beta–endorphin binds to specific receptors in rat peripheral tissues and stimulates the adenylate cyclase–adenosine 3',5'–monophosphate system. Dave JR, et al. **Endocrinology** 1985 Oct; 117(4):1389–96

Phencyclidine and sigma opiate receptors in brain: biochemical and autoradiographical differentiation. Gundlach AL, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):465–6

Increased affinity and selectivity of enkephalin tripeptide (Tyr–D–Ala–Gly) dimers. Lutz RA, et al. **Eur J Pharmacol** 1985 May 8;111(2):257–61

Beta–endorphin does not protect alkylation of opiate receptor by N–ethylmaleimide. Westphal M, et al. **Int J Pept Protein Res** 1985 Apr; 25(4):403–7

Isolation of a specific mu–opiate receptor peptide, morphiceptin, from an enzymatic digest of milk proteins. Chang KJ, et al. **J Biol Chem** 1985 Aug 15;260(17):9706–12

Covalent labeling of opioid receptors with radioiodinated human beta–endorphin. Identification of binding site subunit. Howard AD, et al. **J Biol Chem** 1985 Sep 5;260(19):10833–9

Interaction of opiates with opioid binding sites in the bovine adrenal medulla: I. Interaction with delta and mu sites. Castanas E, et al. **J Neurochem** 1985 Sep;45(3):677–87

Kappa–binding and degradation of [3H]dynorphin A (1–8) and [3H]dynorphin A (1–9) in suspensions of guinea pig brain membranes. Gillan MG, et al. **J Neurochem** 1985 Oct;45(4):1034–42

Diuresis and suppression of vasopressin by kappa opioids: comparison with mu and delta opioids and clonidine. Leander JD, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):463–9

Lack of functional evidence for the involvement of sigma opiate receptors in the actions of the 3–PPP enantiomers on central dopaminergic systems: discrepancies between in vitro and in vivo observations. Hjorth S, et al. **Life Sci** 1985 Aug 19;37(7):673–84

Effects of ketamine on the dynorphin levels and the ethylketocyclazocine (EKC) receptor binding in discrete regions of rat brains. Pongdhana K, et al. **Neurochem Res** 1985 Jul;10(7):945–52

Interaction of dynorphin with kappa opioid receptors in bovine adrenal medulla. Dumont M, et al. **Neuropeptides** 1985 Jul;6(4):321–9

Sulfonic acid enkephalin: binding specificity to rat brain opiate receptors. Martin JL, et al. **Neuropeptides** 1985 Jul;6(4):293–302

Ontogeny and regional distribution of proenkephalin– and prodynorphin–derived peptides and opioid receptors in rat hippocampus. Zamir N, et al. **Neuroscience** 1985 Aug;15(4):1025–34

Central effects of mu, delta, and kappa receptor agonists in hemorrhagic shock. Feuerstein G, et al. **Peptides (Fayetteville)** 1985; 6 Suppl 1:11–3

Changes in brain opiate receptors in rats with isolation syndrome. Petkov VV, et al. **Pharmacol Res Commun** 1985 Jun;17(6):575–84

The Wellcome Foundation lecture, 1982. Opioid Peptides and their Receptors. Kosterlitz HW. **Proc R Soc Lond [Biol]** 1985 Jul 22; 225(1238):27–40 (48 ref.)

[Differential method of analyzing ligand complex formation with binding centers. The detection of the superhigh–affinity binding centers of opiate ligands] Zaitsev SV, et al. **Dokl Akad Nauk SSSR** 1985; 281(3):727–31 **(Rus)**

RECEPTORS, GABA-BENZODIAZEPINE

Micromolar benzodiazepine binding sites of central type characteristics are present in the cerebral cortex of the rat. Lowenstein PR, et al. **Acta Physiol Pharmacol Latinoam** 1984;34(4):441–3

Late evolutionary appearance of 'peripheral–type' binding sites for benzodiazepines. Bolger GT, et al. **Brain Res** 1985 Jul 15; 338(2):366–70

Involvement of benzodiazepine recognition sites in the foot shock–induced decrease of low affinity GABA receptors in the rat cerebral cortex. Concas A, et al. **Brain Res** 1985 Aug 19;341(1):50–6

Correlation of [3H]diazepam binding density with anxiolytic locus in the amygdaloid complex of the rat. Thomas SR, et al. **Brain Res** 1985 Sep 2;342(1):85–90

GABA activates different types of chloride–conducting receptor–ionophore complexes in a dose–dependent manner. Yasui S, et al. **Brain Res** 1985 Sep 30;344(1):176–80

Evidence that a benzodiazepine receptor mechanism regulates the secretion of pituitary beta–endorphin in rats. Maiewski SF, et al. **Endocrinology** 1985 Aug;117(2):474–80

Effects of GABA receptor agonists on [3H]dopamine release from median eminence and pituitary neurointermediate lobe. Anderson R, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):109–12

Effects of PK 8165, a partial benzodiazepine receptor agonist, on cholecystokinin–induced activation of hippocampal pyramidal neurons: a microiontophoretic study in the rat. Bradwejn J, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):415–8

Benzodiazepine receptor binding with a new ligand, Ro 22–8515. Goeders NE, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):147–8

Actions and interactions of benzodiazepine agonists, antagonists and inverse agonists on suprahyoid muscle twitching. James V, et al. **Eur J Pharmacol** 1985 Jul 17;113(2):233–8

Increase in nigral type II benzodiazepine recognition sites following striatonigral denervation. Porceddu ML, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):265–7

Separate site(s) of action of optical isomers of 1–methyl–5–phenyl–5–propylbarbituric acid with opposite pharmacological activities at the GABA receptor complex. Ticku MK, et al. **Eur J Pharmacol** 1985 May 28;112(1):1–9

Neuronal mechanisms involved in drug–induced jumping behavior in mice. Ushijima I, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):225–9

Progabide reverses the nigral substance P reduction induced by chronic impairment of dopaminergic transmission. Zivkovic B, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):253–5

Synthesis and binding studies of 1–arylpyrazolo[4,5–c]– and 2–arylpyrazolo[4,3–c]quinolin–4–ones. I. Cecchi L, et al. **Farmaco [Sci]** 1985 Jul;40(7):509–16

Differential coupling of GABA–A and GABA–B receptors to the noradrenergic system. Suzdak PD, et al. **J Neural Transm** 1985; 62(1–2):77–89

Existence of sites for anions and divalent cations in the solubilized gamma–aminobutyric acid/benzodiazepine receptor complex. Gavish M, et al. **J Neurochem** 1985 Sep;45(3):760–5

Photoaffinity labelling of benzodiazepine receptors: lack of effect on ligand binding to the nucleoside transport system. Hammond JR. **J Neurochem** 1985 Oct;45(4):1327–30

Modulation of neurotransmitter action: control of the gamma–aminobutyric acid response through the benzodiazepine receptor. Chan CY, et al. **J Neurosci** 1985 Sep;5(9):2365–73

Upregulation of gamma–aminobutyric acid (GABA) B binding sites in rat frontal cortex: a common action of repeated administration of different classes of antidepressants and electroshock. Lloyd KG, et al. **J Pharmacol Exp Ther** 1985 Oct;235(1):191–9

The sensitivity of GABA–receptor is increased by biogenic amines. Koketsu K, et al. **Kurume Med J** 1984;31(4):331–4

Molecular structure of Ro15–1788 and a model for the binding of benzodiazepine receptor ligands. Structural identification of common features in antagonists. Codding PW, et al. **Mol Pharmacol** 1985 Aug; 28(2):178–84

Theoretical structure–activity studies of beta–carboline analogs. Requirements for benzodiazepine receptor affinity and antagonist activity. Loew GH, et al. **Mol Pharmacol** 1985 Jul;28(1):17–31

Effect of picrotoxinin on benzodiazepine receptor binding. Chweh AY, et al. **Neurochem Res** 1985 Jul;10(7):871–7

Modulation of specific [3H]phenytoin binding by benzodiazepines. Spero L. **Neurochem Res** 1985 Jun;10(6):755–65

Further characterization of [3H] flunitrazepam binding sites on cultured mouse astroglia. Tardy M, et al. **Neurochem Res** 1985 Jun; 10(6):809–17

Tolerance to the anticonvulsant action of benzodiazepines. Relationship to decreased receptor density. Rosenberg HC, et al. **Neuropharmacology** 1985 Jul;24(7):639–44

Selective blockade of benzodiazepine receptors by Ro 15–1788 prevents foot shock–induced decrease of low affinity gamma–aminobutyric acid receptors. Corda MG, et al. **Neurosci Lett** 1985 May 23;56(3):265–9

Antagonistic effect of delta–aminovaleric acid on bicuculline–insensitive gamma–aminobutyric acid B (GABA B) sites in the rat's brain. Nakahiro M, et al. **Neurosci Lett** 1985 Jun 24;57(3):263–6

The development of type I and type II benzodiazepine receptors in the mouse cortex and cerebellum. Garrett KM, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):985–92

Benzodiazepine–receptor mediated inhibition of isolation–induced aggression in mice. Skolnick P, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):17–20

Neurochemical studies on GABAergic and aminergic systems in the rat brain following acute and chronic piracetam administration. Masotto C, et al. **Pharmacol Res Commun** 1985 Aug;17(8):749–72

Demonstration of benzodiazepine–like molecules in the mammalian brain with a monoclonal antibody to benzodiazepines. Sangameswaran L, et al. **Proc Natl Acad Sci USA** 1985 Aug;82(16):5560–4

The effects of compounds related to gamma–aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: choice behaviour in the T–maze. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;86(3):328–33

[3 new GABA–ergics: research on their possible site of action] Vamvakidès A. **Agressologie** 1985 Jun;26(7):591–4 (Eng. Abstr.) **(Fre)**

[Effects of calcium hopantenate on GABA receptors in the aged rat brain cortex] Ogawa N, et al. **Nippon Ronen Igakkai Zasshi** 1985 May; 22(3):264–5 **(Jpn)**

[Effect of fenibut on the GABA B receptors of the spinal motor neurons] Abramets II, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):698–700 (Eng. Abstr.) **(Rus)**

RECEPTORS, SEROTONIN

Lactate-induced panic attacks: possible involvement of serotonin reuptake stimulation. Lingjaerde O. **Acta Psychiatr Scand** 1985 Aug; 72(2):206–8

Serotonin-induced contraction of canine saphenous vein: mediation by 5-HT1 receptors. Tuncer M, et al. **Arch Int Pharmacodyn Ther** 1985 Apr;274(2):305–12

Selective interaction of novel anxiolytics with 5-hydroxytryptamine1A receptors. Peroutka SJ. **Biol Psychiatry** 1985 Sep;20(9):971–9

Two types of receptors for 5-hydroxytryptamine on the cholinergic nerves of the guinea-pig myenteric plexus. Kilbinger H, et al. **Br J Pharmacol** 1985 Jun;85(2):529–39

Stimulation of spinal serotonergic receptors facilitates seminal emission and suppresses penile erectile reflexes. Mas M, et al. **Brain Res** 1985 Sep 2;342(1):128–34

2-Nitroimipramine: a photoaffinity probe for the serotonin uptake/tricyclic binding site complex. Wennogle LP, et al. **EMBO J** 1985 Apr;4(4):971–7

Short-term lithium administration enhances serotonergic neurotransmission: electrophysiological evidence in the rat CNS. Blier P, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):69–77

DSP-4 lesioning prevents the enhancement of dopamine and 5-hydroxytryptamine mediated behavioural changes by repeated electroconvulsive shock. Heal DJ, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):117–21

Presynaptic dopamine and serotonin receptors modulating tyrosine hydroxylase activity in synaptosomes of the nucleus accumbens of rats. Hetey L, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):1–10

Neuronal mechanisms involved in drug-induced jumping behavior in mice. Ushijima I, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):225–9

Elevated density of [3H]imipramine binding in aged human brain. Severson JA, et al. **J Neurochem** 1985 Nov;45(5):1382–9

Specific antagonism of enteric neural serotonin receptors by dipeptides of 5-hydroxytryptophan: evidence that serotonin is a mediator of slow synaptic excitation in the myenteric plexus. Takaki M, et al. **J Neurosci** 1985 Jul;5(7):1769–80

The putative 5-HT1 receptor agonist, RU 24969, inhibits the efflux of 5-hydroxytryptamine from rat frontal cortex slices by stimulation of the 5-HT autoreceptor. Middlemiss DN. **J Pharm Pharmacol** 1985 Jun; 37(6):434–7

Acetylcholine- and 5-hydroxytryptamine-stimulated contraction and calcium uptake in bovine coronary arteries: evidence for two populations of receptor-operated calcium channels. Ratz PH, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):641–7

Target size analysis of serotonin 5-HT1 and 5-HT2 receptors in bovine brain membranes. Nishino N, et al. **Life Sci** 1985 Sep 23; 37(12):1167–74

Presynaptic serotonin receptor-mediated response in mice attenuated by antidepressant drugs and electroconvulsive shock. Goodwin GM, et al. **Nature** 1985 Oct 10–16;317(6037):531–3

Analysis of the heart rate effects of 5-hydroxytryptamine in the cat; mediation of tachycardia by 5-HT1-like receptors. Saxena PR, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):121–9

Reduced head-twitch response to quipazine of rats previously treated with methiothepin: possible involvement of dopaminergic system. Dall'Olio R, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):43–8

Serotonin involvement in lisuride-induced mounting and in sleep. Da Prada M, et al. **Pharmacopsychiatry** 1985 Mar;18(2):202–8

Receptor-mediated regulation of 5-hydroxytryptamine metabolism: current knowledge and open questions. Kehr W. **Pharmacopsychiatry** 1985 Mar;18(2):193–7

Human aggression and the role of central serotonin. Mühlbauer HD. **Pharmacopsychiatry** 1985 Mar;18(2):218–21

The importance of brain serotonergic receptor mechanisms for the action of antidepressant drugs. Ogren SO, et al. **Pharmacopsychiatry** 1985 Mar; 18(2):209–13

The 5-HT syndrome and the drug discrimination paradigm in rats: application in behavioral studies on the central 5-HT system. Ortmann R. **Pharmacopsychiatry** 1985 Mar;18(2):198–201

Circadian variation in behavioural responses to central 5-HT receptor stimulation in the mouse. Moser PC, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):223–7

[Characteristics of serotonin binding by the cells of immunocompetent tissues and synaptosomes] Eliseeva LS, et al. **Biull Eksp Biol Med** 1985 Aug;100(8):210–3 (Eng. Abstr.) **(Rus)**

[Correlation between the number of serotonin type 2 receptors in the frontal cortex of the mouse brain and the expressivity of serotonin-dependent head twitches] Popova NK, et al. **Biull Eksp Biol Med** 1985 Sep;100(9):322–4 (Eng. Abstr.) **(Rus)**

[Effect of carbidine on the dopamine and serotonin receptors of the central nervous system] Zharkovskiĭ AM, et al. **Biull Eksp Biol Med** 1985 Jun; 99(6):700–2 (Eng. Abstr.) **(Rus)**

REFLEX

Effects of nasal capsaicin pretreatment and cryosurgery on sneezing reflexes, neurogenic plasma extravasation, sensory and sympathetic neurons. Lundblad L, et al. **Acta Otolaryngol (Stockh)** 1985 Jul–Aug; 100(1–2):117–27

Participation of the beta-adrenergic receptor in the enteroruminal reflex and enteroenteric reflex. Wegrzyn T, et al. **Acta Physiol Pol** 1984 May–Jun;35(3):193–8

Apparent reduction in baroreflex sensitivity to adenosine in conscious dogs. Hintze TH, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):H554–9

Role of the pituitary in reflex natriuresis following acute unilateral nephrectomy. Lin SY, et al. **Am J Physiol** 1985 Aug; 249(2 Pt 2):F282–90

Infusion of branched-chain amino acids and ammonium salts in rats with portacaval shunts. Rigotti P, et al. **Arch Surg** 1985 Nov; 120(11):1290–5

Lower body negative pressure in the tranquilized rat. Bedford TG, et al. **Aviat Space Environ Med** 1985 Aug;56(8):786–90

The effect of enalapril on baroreceptor mediated reflex function in normotensive subjects. Giudicelli JF, et al. **Br J Clin Pharmacol** 1985 Sep;20(3):211–8

Stimulation of spinal serotonergic receptors facilitates seminal emission and suppresses penile erectile reflexes. Mas M, et al. **Brain Res** 1985 Sep 2;342(1):128–34

Inhibition of the baroreceptor heart rate reflex by angiotensin II in normal man. Mace PJ, et al. **Cardiovasc Res** 1985 Sep;19(9):525–7

Effects of a new benzodiazepine derivative, ethyl loflazepate (CM6912), on the arousal level of normal humans assessed by the averaged photopalpebral reflex. Tanaka M, et al. **Clin Neuropharmacol** 1985; 8(3):271–9

Reflex responses to reductions in functioning renal mass. Humphreys MH, et al. **Fed Proc** 1985 Oct;44(13):2840–5 (40 ref.)

The effects of buspirone, BMY-13805 and 1-(2-pyrimidinyl)-piperazine on cat spinal reflexes. Matheson GK, et al. **Methods Find Exp Clin Pharmacol** 1985 May;7(5):231–8

Yawning elicited by systemic and intrastriatal injection of piribedil and apomorphine in the rat. Dourish CT, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):175–81

REINFORCEMENT (PSYCHOLOGY)

The conditioned place preference is affected by two independent reinforcement processes. White NM, et al. **Pharmacol Biochem Behav** 1985 Jul;23(1):37–42

The abolition of the partial reinforcement extinction effect (PREE) by amphetamine. Weiner I, et al. **Psychopharmacology (Berlin)** 1985; 86(3):318–23

REINFORCEMENT SCHEDULE

Comparison of fixed-ratio and progressive-ratio schedules of maintenance of stimulant drug-reinforced responding. Winger G, et al. **Drug Alcohol Depend** 1985 May;15(1–2):123–30

Effects of triethyltin and its interaction with d-amphetamine and chlorpromazine on responding under a multiple schedule of food presentation in rats. Rastogi SK, et al. **Neurobehav Toxicol Teratol** 1985 May–Jun;7(3):239–42

Behavioral screen for antidepressants: the effects of drugs and electroconvulsive shock on performance under a differential-reinforcement-of-low-rate schedule. Seiden LS, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):55–60

RESERPINE

The effect of reserpine on the pars intermedia of the rat pituitary. An electron-microscopic, fluorescence-histochemical and immunohistochemical study. Bäck N, et al. **Cell Tissue Res** 1985; 241(1):1–8

Repetitive measurement of monoamine metabolite levels in cerebrospinal fluid of conscious rats: effects of reserpine and haloperidol. Scheinin H, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):345–51

Demonstration of reduced levels of zinc in rat brain after treatment with d-amphetamine, but not after treatment with reserpine. Szerdahelyi P, et al. **Histochemistry** 1985;83(2):181–7

The influence of reserpine and propranolol upon the IOP response to vanadate in the rabbit. Delamere NA, et al. **Invest Ophthalmol Vis Sci** 1985 Oct;26(10):1442–5

Tricyclic antidepressive treatment reinforced by reserpine. Moscovich D, et al. **Isr J Psychiatry Relat Sci** 1984;21(4):283–9

Determination of reserpine in commercial tablets by liquid chromatography with fluorescence detection. Cieri UR. **J Assoc Off Anal Chem** 1985 May–Jun;68(3):542–4

Reserpic acid as an inhibitor of norepinephrine transport into chromaffin vesicle ghosts. Chaplin L, et al. **J Biol Chem** 1985 Sep 15; 260(20):10981-5

Elevation of RNA coding for tyrosine hydroxylase in rat adrenal gland by reserpine treatment and exposure to cold. Tank AW, et al. **J Neurochem** 1985 Oct;45(4):1030-3

Estradiol increases growth hormone secretion in rats exposed to swimming stress or reserpine treatment. Eriksson E, et al. **Life Sci** 1985 Sep 30; 37(13):1241-8

GABAergic effects of reserpine following chronic treatment. Suzdak PD, et al. **Psychopharmacology (Berlin)** 1985;87(2):157-60

[A TRH analog (DN-1417). Antagonistic effects on reserpine-induced decreases in local cerebral glucose utilization and cerebral monoamine levels] Nagai Y, et al. **Nippon Yakurigaku Zasshi** 1985 May; 85(5):315-26 (Eng. Abstr.) **(Jpn)**

[Effect of reserpine on inhibition of preganglionic neurons induced by stimulation of the vagus nerve] Itina LV. **Fiziol Zh SSSR** 1985 Jun; 71(6):790-2 **(Rus)**

RUBIDIUM

Transepithelial cation movements in gerbil utricles. Marcus NY, et al. **Am J Otolaryngol** 1985 Jul-Aug;6(4):268-74

Determination of lithium, rubidium and strontium in foodstuffs. Evans WH, et al. **Analyst** 1985 Jun;110(6):619-23

Lack of effect of synthetic atrial natriuretic factor on rubidium uptake by human erythrocytes. Hernando N, et al. **Biochem Biophys Res Commun** 1985 Aug 15;130(3):1066-71

Cholinergic stimulation of ion fluxes in pancreatic islets. Mathias PC, et al. **Biochem Pharmacol** 1985 Oct 1;34(19):3451-7

Delta endotoxin inhibits Rb+ uptake, lowers cytoplasmic pH and inhibits a K+-ATPase in Manduca sexta CHE cells. English LH, et al. **J Membr Biol** 1985;85(3):199-204

SCHIZOPHRENIA

An open multicentre study of the treatment of florid schizophrenia with remoxipride. McCreadie RG, et al. **Acta Psychiatr Scand** 1985 Aug; 72(2):139-43

Negative syndrome in schizophrenia: strategies for long-term management. Andreasen NC. **Adv Biochem Psychopharmacol** 1985; 40:1-7

Reduced cholecystokinin levels in the limbic lobe in schizophrenia. A marker for pathology underlying the defect state? Ferrier IN, et al. **Ann NY Acad Sci** 1985;448:495-506

The effects of cholecystokinin-like peptides in schizophrenics and normal human subjects. Hommer DW, et al. **Ann NY Acad Sci** 1985; 448:542-52

Antipsychotic effects of ceruletide in chronic schizophrenia. An appraisal of the long-term, intermittent medication of ceruletide in chronic schizophrenia. Moroji T, et al. **Ann NY Acad Sci** 1985;448:518-34

Clinical and neuroendocrine studies with cholecystokinin peptides. Nair NP, et al. **Ann NY Acad Sci** 1985;448:535-41

Rehabilitation of the chronic schizophrenic: areas of intervention. Jacobs HE, et al. **Annu Rev Rehabil** 1985;4:83-113 (99 ref.)

Family management in the prevention of morbidity of schizophrenia. Clinical outcome of a two-year longitudinal study. Falloon IR, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):887-96

Apomorphine's antipsychotic activity [letter] Schaffer MH, et al. **Arch Gen Psychiatry** 1985 Sep;42(9):927-8

A treatment trial with an analog of thyrotropin-releasing hormone (DN-1417) in schizophrenia. Mizuki Y, et al. **Biol Psychiatry** 1985 Sep; 20(9):1030-5

Pilot study on the effects of fenfluramine on negative symptoms in twelve schizophrenic inpatients. Stahl SM, et al. **Biol Psychiatry** 1985 Oct; 20(10):1098-102

Stable abnormalities in the lateralisation of early cortical somatosensory evoked potentials in schizophrenic patients. Cooper JE, et al. **Br J Psychiatry** 1985 Jun;146:585-93

Long-term depot maintenance of chronic schizophrenic out-patients: the seven year follow-up of the Medical Research Council fluphenazine/placebo trial. III. Relapse postponement or relapse prevention? The implications for long-term outcome. Curson DA, et al. **Br J Psychiatry** 1985 May;146:474-80

Long-term depot maintenance of chronic schizophrenic out-patients: the seven year follow-up of the Medical Research Council fluphenazine/placebo trial I. Course of illness, stability of diagnosis, and the role of a special maintenance clinic. Curson DA, et al. **Br J Psychiatry** 1985 May;146:464-9

Lorazepam dependence and chronic psychosis [letter] Fraser AA, et al. **Br J Psychiatry** 1985 Aug;147:211

Erotomania in Schneider-positive schizophrenia. A case report. Hayes M, et al. **Br J Psychiatry** 1985 Jun;146:661-3

A controlled trial of social intervention in the families of schizophrenic patients: two year follow-up. Leff J, et al. **Br J Psychiatry** 1985 Jun; 146:594-600

Changes in the diagnoses of the functional psychoses associated with the introduction of lithium. Parker G, et al. **Br J Psychiatry** 1985 Apr; 146:377-82

Neuroleptic serum levels measured by radioreceptor assay in patients receiving intramuscular depot neuroleptics. Some preliminary findings. Turbott J, et al. **Br J Psychiatry** 1985 Apr;146:439-42

Prediction of response to neuroleptic drug therapy in schizophrenia. Awad AG. **Can J Psychiatry** 1985 Jun;30(4):241-2

Early subjective response and prediction of outcome to neuroleptic drug therapy in schizophrenia. Hogan TP, et al. **Can J Psychiatry** 1985 Jun; 30(4):246-8

Schizophrenia: an amotivational syndrome in men. Lewine R. **Can J Psychiatry** 1985 Aug;30(5):316-8 (17 ref.)

Clinical and demographic correlates of neuroleptic response. Seeman MV. **Can J Psychiatry** 1985 Jun;30(4):243-5

Prediction of treatment response in schizophrenia: clinical use of neuroleptic blood levels. Tang SW. **Can J Psychiatry** 1985 Jun; 30(4):249-50

Liquid-chromatographic assay of diazepam and its major metabolites in serum, and application to pharmacokinetic study of high doses of diazepam in schizophrenics. Tada K, et al. **Clin Chem** 1985 Oct; 31(10):1712-5

Ten-year follow-up of schizophrenic patients on pipothiazine palmitate. Imlah NW, et al. **Curr Med Res Opin** 1985;9(7):449-53

Multidimensional study of the outcome of schizophrenic patients 1 year after clinic discharge. Predictors and influence of neuroleptic treatment. Gaebel W, et al. **Eur Arch Psychiatry Neurol Sci** 1985;235(1):45-52

The schizophrenic clients reinforcement and punishment for medication adherence. Davidhizar R. **Issues Ment Health Nurs** 1984; 6(1-2):173-87

Comparison of injectable molindone and haloperidol followed by oral dosage forms in acutely ill schizophrenics. Escobar JI, et al. **J Clin Psychiatry** 1985 Aug;46(8 Pt 2):15-9

The strategy and value of neuroleptic drug monitoring. Curry SH. **J Clin Psychopharmacol** 1985 Oct;5(5):263-71 (56 ref.)

On the clinical relevance and methods of quantification of plasma concentrations of neuroleptics. Ko GN, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):253-62 (49 ref.)

Low HVA and normal 5HIAA CSF levels in drug-free schizophrenic patients compared to healthy volunteers: correlations to symptomatology and family history. Lindström LH. **Psychiatry Res** 1985 Apr;14(4):265-73

Social skills training for patients with schizophrenia: a controlled clinical trial. Wallace CJ, et al. **Psychiatry Res** 1985 Jul;15(3):239-47

CSF monoamine metabolites in chronic schizophrenic patients who attempt suicide. Roy A, et al. **Psychol Med** 1985 May;15(2):335-40

Evidence for a daily rhythm of plasma HVA in normal controls but not in schizophrenic patients. Doran AR, et al. **Psychopharmacol Bull** 1985; 21(3):694-7

High-dose versus low-dose strategies in the treatment of schizophrenia. Kane JM, et al. **Psychopharmacol Bull** 1985;21(3):533-7

Dopamine receptor binding of C-11-3-N-methylspiperone in the caudate in schizophrenia and bipolar disorder: a preliminary report. Wong DF, et al. **Psychopharmacol Bull** 1985;21(3):595-8

An open study of remoxipride, a benzamide derivative, in schizophrenia. Lindström L, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):241-3

Early relapse after sudden withdrawal or dose reduction of clozapine [letter] Perényi A, et al. **Psychopharmacology (Berlin)** 1985; 86(1-2):244

Comparative efficacy of red cell and plasma haloperidol as predictors of clinical response in schizophrenia. Smith RC, et al. **Psychopharmacology (Berlin)** 1985;85(4):449-55

Treatment of negative symptoms. Carpenter WT Jr, et al. **Schizophr Bull** 1985;11(3):440-52

The two-syndrome concept: origins and current status. Crow TJ. **Schizophr Bull** 1985;11(3):471-86

Negative and deficit symptoms in schizophrenia do respond to neuroleptics. Goldberg SC. **Schizophr Bull** 1985;11(3):453-6

Informed consent in psychiatric research: preliminary findings from an ongoing investigation. Benson PR, et al. **Soc Sci Med** 1985; 20(12):1331-41

Comparative determination of flupentixol in plasma by gas chromatography and radioimmunoassay in schizophrenic patients. Balant-Gorgia AE, et al. **Ther Drug Monit** 1985;7(2):229-35

A group approach to psychopharmacology with schizophrenics. Skolnick MR. **Yale J Biol Med** 1985 Jul-Aug;58(4):317-26

[Changes in the CSF levels of monoamine metabolites in 102 chronic schizophrenic patients following probenecid before and after neuroleptic medication] Chen YF. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Oct; 17(5):273-7 (Eng. Abstr.) **(Chi)**

[An analysis of 106 cases of schizophrenia treated with clozapine] Yang JS. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Aug; 17(4):242-4 (Eng. Abstr.) **(Chi)**

[Positive reaction of serum anti-DNA antibody induced by phenothiazines in schizophrenic patients] Yang JS. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Dec; 17(6):333-5 (Eng. Abstr.) **(Chi)**

[Administration of maintenance therapy in endogenous psychoses in out-patient practice] Mrňa B, et al. **Cesk Psychiatr** 1985 Aug; 81(4):273-5 (Eng. Abstr.) **(Cze)**

[Clinical effectiveness of isofloxythepin—an open study] Zapletálek M, et al. **Cesk Psychiatr** 1985 Aug;81(4):242-6 (Eng. Abstr.) **(Cze)**

[Catecholaminergic receptors of the blood cells of schizophrenics] Ackenheil M, et al. **Encephale** 1985 May-Jun;11(3):95-100 (Eng. Abstr.) **(Fre)**

[Immunoglobulins of classes G, A and M in the serum of schizophrenics] Burbaeva GSh, et al. **Zh Nevropatol Psikhiatr** 1985;85(6):901-5 (Eng. Abstr.) **(Rus)**

SCHIZOPHRENIA, PARANOID

Vasopressin—oxytocin in cerebrospinal fluid of schizophrenic patients and normal controls. Beckmann H, et al. **Psychoneuroendocrinology** 1985; 10(2):187-91

SELF STIMULATION

Psychopharmacological profile of cholecystokinin using the self-stimulation and the drug discrimination paradigms. De Witte P, et al. **Ann NY Acad Sci** 1985;448:470-87

A response-specific conditioned aversion to rewarding hypothalamic stimulation in rats. Greenshaw AJ, et al. **Brain Res** 1985 Jul 22; 339(1):130-5

Behavioral and neurochemical effects of deprenyl and beta-phenylethylamine in Wistar rats. Greenshaw AJ, et al. **Brain Res Bull** 1985 Aug;15(2):183-9

Unilateral lesion of the intrinsic cells in the medial forebrain bundle depresses self-stimulation but not stimulus-bound locomotor activity. Velley L. **Neurosci Lett** 1985 Jun 12;57(2):199-204

Selective neonatal depletion of dopamine has no effect on medial prefrontal cortex self-stimulation in the rat. Umemoto M, et al. **Neurosci Res** 1984 Oct;1(5):295-307

Electrical self-stimulation deficits in the anterior and posterior parts of the medial forebrain bundle after ibotenic acid lesion of the middle lateral hypothalamus. Lestang I, et al. **Neuroscience** 1985 Jun; 15(2):379-88

[Endogenous peptides in the organization of somato-vegetative responses to hypothalamic stimulation] Badikov VI, et al. **Fiziol Zh SSSR** 1985 Jul;71(7):840-7 (Eng. Abstr.) **(Rus)**

SENSORY DEPRIVATION

Unilateral odor deprivation: effects on the development of olfactory bulb catecholamines and behavior. Brunjes PC, et al. **Brain Res** 1985 Sep; 354(1):1-6

The effects of monocular deprivation on the size of GAD+ neurons in the cat's dorsal lateral geniculate nucleus. Robson JA, et al. **J Comp Neurol** 1985 Sep 1;239(1):62-74

SEROTONIN

Sexual differences in the effect of serotonin on LH secretion in rats. Moguilevsky JA, et al. **Acta Endocrinol (Copenh)** 1985 Jul; 109(3):320-5

A series of new antileprosy compounds derived from serotonin. Mester de Parajd L, et al. **Acta Leprol (Geneve)** 1985 Jan-Mar;(96):21-8

The participation of serotoninergic system in the regulation of emotional-defensive behavior evoked by intrahypothalamic carbachol injections in the cat. Gołebiewski H, et al. **Acta Neurobiol Exp (Warsz)** 1985;45(1-2):25-36

Quantity of DNA in the organs of 19-day-old foetuses after AET, MEA, or 5-HT treatment of mice on the first day of gestation. Mazur L. **Acta Physiol Hung** 1985;66(1):65-8

Effects of histamine and cimetidine on the levels of serotonin and 5-hydroxyindoleacetic acid in various parts of the digestive tract and in the blood and brain of rats. Kleinrok Z, et al. **Acta Physiol Pol** 1984 Mar-Apr;35(2):125-30

Lactate-induced panic attacks: possible involvement of serotonin reuptake stimulation. Lingjaerde O. **Acta Psychiatr Scand** 1985 Aug; 72(2):206-8

From clomipramine to mianserin: therapeutic relevance of interactions with serotonin uptake and storage, as studied in the blood platelet model. Lingjaerde O. **Acta Psychiatr Scand [Suppl]** 1985;320:10-9 (18 ref.)

Distribution of 5-hydroxytryptamine (5HT) in tissue of a mutant mouse deficient in mast cell (W/Wv). Demonstration of the contribution of mast cells to the 5HT content in various organs. Inoue F, et al. **Agents Actions** 1985 Jul;16(5):295-301

Serotonin content of foods: effect on urinary excretion of 5-hydroxyindoleacetic acid. Feldman JM, et al. **Am J Clin Nutr** 1985 Oct;42(4):639-43

Effect of gastrin, histamine, serotonin, and adrenergic amines on gastroesophageal sphincter pressure in the dog. Strombeck DR, et al. **Am J Vet Res** 1985 Aug;46(8):1684-90

Application of the dual-cell coulometric detector: a method for assaying monoamines and their metabolites. Achilli G, et al. **Anal Biochem** 1985 Jul;148(1):1-9

Substance P and 5-hydroxytryptamine immunoreactive presynaptic boutons on presumed alpha-motoneurons in the chicken ventral horn. Atsumi S, et al. **Arch Histol Jpn** 1985 Apr;48(2):159-72

Serotonin-induced contraction of canine saphenous vein: mediation by 5-HT1 receptors. Tuncer M, et al. **Arch Int Pharmacodyn Ther** 1985 Apr;274(2):305-12

ATP depletion in human platelets caused by permeabilization with saponin does not prevent serotonin secretion induced by collagen. Ruggiero M, et al. **Biochem Biophys Res Commun** 1985 Sep 16;131(2):620-7

Muramyl peptides and serotonin interact at specific binding sites on macrophages and enhance superoxide release. Silverman DH, et al. **Biochem Biophys Res Commun** 1985 Sep 30;131(3):1160-7

Effect of superior cervical ganglionectomy on melatonin stimulation by specific MAO-A inhibition. McIntyre IM, et al. **Biochem Pharmacol** 1985 Sep 15;34(18):3393-4

High concentrations of arachidonic acid induce platelet aggregation and serotonin release independent of prostaglandin endoperoxides and thromboxane A2. Hashimoto Y, et al. **Biochim Biophys Acta** 1985 Sep 6;841(3):283-91

Biological stress responses in high and low trait anxious students. Davis DD, et al. **Biol Psychiatry** 1985 Aug;20(8):843-51

Daily patterns of serotonin uptake in platelets from psychiatric patients and control volunteers. Humphries LL, et al. **Biol Psychiatry** 1985 Oct; 20(10):1073-81

Inhibition of monoamine oxidase in 5-hydroxytryptaminergic neurones by substituted p-aminophenylalkylamines. Ask AL, et al. **Br J Pharmacol** 1985 Jul;85(3):683-90

Response and sensitivity of guinea-pig airway muscle preparations to 5-hydroxytryptamine during ontogenesis. Bayol A, et al. **Br J Pharmacol** 1985 Jul;85(3):569-74

Effects of intracerebral injections of quinolinic acid on serotonergic neurons in the rat brain. Aldinio C, et al. **Brain Res** 1985 Aug 19; 341(1):57-65

The involvement of serotonin neurones in the inhibition of renal nerve activity during desynchronized sleep. Coote JH, et al. **Brain Res** 1985 Aug 12;340(2):277-84

The possible modulation of the development of rat dorsal root ganglion cells by the presence of 5-HT-containing neurones of the brainstem in dissociated cell culture. Forda S, et al. **Brain Res** 1985 Sep; 354(1):55-65

Intrahypothalamic 5,7-dihydroxytryptamine: temporal analysis of effects on 5-hydroxytryptamine content in brain nuclei and on facilitated lordosis behavior. Frankfurt M, et al. **Brain Res** 1985 Aug 5; 340(1):127-33

Serotonergic innervation of cat cerebral arteries. Marco EJ, et al. **Brain Res** 1985 Jul 8;338(1):137-9

Regulation of central alpha-adrenoceptors by serotoninergic denervation. Rappaport A, et al. **Brain Res** 1985 Sep 30;344(1):158-61

Sodium-independent binding of [3H]cocaine in mouse striatum is serotonin related. Reith ME, et al. **Brain Res** 1985 Sep 2;342(1):145-8

Neurochemical studies on the existence, origin and characteristics of the serotonergic innervation of small pial vessels. Scatton B, et al. **Brain Res** 1985 Oct 21;345(2):219-29

Reversal of the sexually dimorphic distribution of serotonin-immunoreactive fibers in the medial preoptic nucleus by treatment with perinatal androgen. Simerly RB, et al. **Brain Res** 1985 Aug 5;340(1):91-8

Norepinephrine stimulates serotonin secretion from rat pineal glands, in vitro. Walker RF, et al. **Brain Res** 1985 Sep 16;343(1):188-9

Monoamine transmitter release induced by tetrahydro-beta-carboline perfused in hippocampus of the unrestrained rat. Huttunen P, et al. **Brain Res Bull** 1985 Aug;15(2):215-20

Serotonergic modulation of the feeding behavior of the medicinal leech. Lent CM. **Brain Res Bull** 1985 Jun;14(6):643-55

ACh and 5-HT stimulated thermogenesis at different core temperatures in the He-Cold hypothermic hamster. Simpson CW, et al. **Brain Res Bull** 1985 Aug;15(2):123-7

Isolation of glomeruli from areas of bovine cerebellum and comparison of [3H]serotonin uptake. Terrian DM, et al. **Brain Res Bull** 1985 May; 14(5):469-75

Calcium regulates the activity of serotonin-containing dorsal raphe neurons in vitro. Trulson ME, et al. **Brain Res Bull** 1985 Aug; 15(2):107-10

On the interaction between 5-hydroxytryptamine and N-acetylneuraminic acid under aqueous conditions. Berry LR, et al. **Can J Biochem Cell Biol** 1985 Jul;63(7):757-63

Action of serotonin and norepinephrine on spinal motoneurones following blockade of synaptic transmission. Neuman RS. **Can J Physiol Pharmacol** 1985 Jun;63(6):735-8

Localization of serotonin in the hypothalamus and the mesencephalon of the guinea-pig. An immunohistochemical study using monoclonal antibodies. Warembourg M, et al. **Cell Tissue Res** 1985; 240(3):711-21

Morphological and pharmacological analysis of putative serotonergic bipolar and amacrine cells in the retina of a turtle, Pseudemys scripta elegans. Weiler R, et al. **Cell Tissue Res** 1985;241(2):373-82

Rapid procedure for finger-stick whole-blood analysis for serotonin by electrochemical-array-cell liquid chromatography [letter] Matson WR, et al. **Clin Chem** 1985 Aug;31(8):1407

Precise determination of 5-hydroxytryptamine in platelets and platelet-poor plasma [letter] Molyneux SG, et al. **Clin Chem** 1985 Sep; 31(9):1573-4

Amine-containing neurons in the brain of Lymnaea stagnalis: distribution and effects of precursors. Audesirk G. **Comp Biochem Physiol [A]** 1985; 81(2):359-65

2-Nitroimipramine: a photoaffinity probe for the serotonin uptake/tricyclic binding site complex. Wennogle LP, et al. **EMBO J** 1985 Apr;4(4):971-7

Effect of microelectrophoretically applied acetylcholine, noradrenaline, dopamine and serotonin on the discharge of paraventricular oxytocinergic neurones in the rat. Honda K, et al. **Endocrinol Jpn** 1985 Feb;32(1):127-33

Thyrotropin-releasing hormone release from rat pancreas is stimulated by serotonin but inhibited by carbachol. Lamberton P, et al. **Endocrinology** 1985 Nov;117(5):1834-8

Rapid bidirectional effects of insulin on hypothalamic noradrenergic and serotoninergic neuronal activity in the rat: role in glucose homeostasis. Smythe GA, et al. **Endocrinology** 1985 Oct;117(4):1590-7

Characterization of [3H]5-hydroxytryptamine uptake within rat cerebrovascular tree. Amenta F, et al. **Eur J Pharmacol** 1985 Jun 7; 112(2):181-6

Pharmacological analysis of 5-hydroxytryptamine actions on guinea-pig ileal mucosa. Cooke HJ, et al. **Eur J Pharmacol** 1985 May 20; 111(3):329-37

Effect of substances influencing brain serotonergic transmission on plasma vasopressin levels in the rat. Iovino M, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):99-103

Chronic clonidine induces functional down-regulation of presynaptic alpha 2-adrenoceptors regulating [3H]noradrenaline and [3H]5-hydroxytryptamine release in the rat brain. Maura G, et al. **Eur J Pharmacol** 1985 May 28;112(1):105-10

Quinolinic acid stimulates luteinizing hormone secretion through a serotonin-dependent mechanism. Johnson MD, et al. **Exp Brain Res** 1985;59(1):62-7

Schistosoma mansoni: effects of in vitro serotonin (5-HT) on aerobic and anaerobic carbohydrate metabolism. Rahman MS, et al. **Exp Parasitol** 1985 Aug;60(1):10-7

Serotonergic and cholinergic interaction in the regulation of pituitary-adrenal function in rats. Kile JP, et al. **Experientia** 1985 Sep 15;41(9):1123-7

Serotonergic conversion of MPTP and dopaminergic accumulation of MPP+. Shen RS, et al. **FEBS Lett** 1985 Sep 23;189(2):225-30

Relation between inhibition of calmodulin and mediator release from rat mast cells. Ohishi K, et al. **Gen Pharmacol** 1985;16(4):335-9

Ultrastructural immunocytochemical co-localization of serotonin and PNMT in adrenal medullary vesicles. Brownfield MS, et al. **Histochemistry** 1985;83(1):41-6

Studies on in vitro effect of serotonin on calcitonin secretion by rat thyroid C cells. Zabel M. **Histochemistry** 1985;83(1):71-5

Evidence for serotoninergic control of exercise-induced prolactin secretion. De Meirleir K, et al. **Horm Metab Res** 1985 Jul; 17(7):380-1

The neurochemistry of mania. The effect of lithium on catecholamines, indoleamines and calcium mobilization. Wood K. **J Affective Disord** 1985 May-Jun;8(3):215-23

Inhibition of fibrinogen receptor expression and serotonin release by leupeptin and antipain. Baldassare JJ, et al. **J Biol Chem** 1985 Sep 5; 260(19):10531-5

Serotonergic mechanisms in the cardiovascular system. **J Cardiovasc Pharmacol** 1985;7 Suppl 7:S1-182

Platelet hypersensitivity to serotonin after prolonged ketanserin intake? Arnout J, et al. **J Cardiovasc Pharmacol** 1985;7 Suppl 7:S20-2

Serotonin release and phosphoinositide breakdown in thrombin-induced activation of human platelets. Marche P, et al. **J Cardiovasc Pharmacol** 1985;7 Suppl 7:S18-9

Serotonin-induced vasoconstriction in the perfused canine femoral artery can be blocked in vivo by ketanserin. Meschig R, et al. **J Cardiovasc Pharmacol** 1985;7 Suppl 7:S56-9

In vitro studies on responses to noradrenaline, serotonin, and potassium of intramyocardial and mesenteric resistance vessels from Wistar rats. Nyborg NC, et al. **J Cardiovasc Pharmacol** 1985 May-Jun; 7(3):417-23

Serotonin depression of local cerebral glucose utilisation after monoamine oxidase inhibition. Grome JJ, et al. **J Cereb Blood Flow Metab** 1985 Sep;5(3):473-5

Determination of serotonin in plasma by liquid chromatography with electrochemical detection. Picard M, et al. **J Chromatogr** 1985 Jun 14; 341(2):445-51

Depression and serotonin metabolism: rationale for neurotransmitter precursor treatment. Byerley WF, et al. **J Clin Psychopharmacol** 1985 Aug;5(4):191-206 (188 ref.)

Localization of some neuropeptide- and serotonin-like immunoreactivities in the vegetative network of guinea pig spinal cord. Davidoff MS, et al. **J Hirnforsch** 1985;26(2):153-65

The effects of different pretreatment conditions and fixation regimes on serotonin immunoreactivity: a quantitative light microscopic study. Clements JR, et al. **J Histochem Cytochem** 1985 Aug;33(8):778-84

Characterization of an immunofluorescence technique for the demonstration of coexisting neurotransmitters within nerve fibers and terminals. Wessendorf MW, et al. **J Histochem Cytochem** 1985 Oct; 33(10):984-94

Spontaneously prolonged dioestrus and serotonin in various regions of the rat brain. Chomicka LK, et al. **J Neural Transm** 1985;63(1):31-8

Monitoring of circadian fluctuations of N-acetylserotonin in the rat pineal body by differential pulse voltammetry. Ikeda M, et al. **J Neural Transm** 1985;62(3-4):321-9

On the nature of the contractile motor responses of the rat stomach elicited by serotonin or substance P in vitro. Lidberg P, et al. **J Neural Transm** 1985;63(1):73-89

Measurement of 5-HIAA levels in ventricular CSF (by LCEC) and in striatum (by in vivo voltammetry) during pharmacological modifications of serotonin metabolism in the rat. Mignot E, et al. **J Neural Transm** 1985;62(1-2):117-24

Serotonin and cyclic adenosine 3':5'-monophosphate modulate the potassium current in tail sensory neurons in the pleural ganglion of Aplysia. Pollock JD, et al. **J Neurosci** 1985 Jul;5(7):1862-71

Depletion of norepinephrine, but not serotonin, reduces long-term potentiation in the dentate gyrus of rat hippocampal slices. Stanton PK, et al. **J Neurosci** 1985 Aug;5(8):2169-76

Serotonin and distribution of radiocarbon from D-[14C-U]-glucose in Schistosoma mansoni. Rahman MS, et al. **J Parasitol** 1985 Aug; 71(4):403-8

The putative 5-HT1 receptor agonist, RU 24969, inhibits the efflux of 5-hydroxytryptamine from rat frontal cortex slices by stimulation of the 5-HT autoreceptor. Middlemiss DN. **J Pharm Pharmacol** 1985 Jun; 37(6):434-7

Serotonergic prejunctional inhibition of canine coronary adrenergic nerves. Cohen RA. **J Pharmacol Exp Ther** 1985 Oct;235(1):76-80

Acetylcholine- and 5-hydroxytryptamine-stimulated contraction and calcium uptake in bovine coronary arteries: evidence for two populations of receptor-operated calcium channels. Ratz PH, et al. **J Pharmacol Exp Ther** 1985 Sep;234(3):641-7

Serotoninergic immunofluorescent nerve fibres appear in human temple skin after lithium treatment [letter] Dhital K, et al. **Lancet** 1985 Oct 5;2(8458):779

In vitro evidence for a blood-borne renin-releasing factor. Urban JH, et al. **Life Sci** 1985 Oct 7;37(14):1335-42

Photoinactivation of serotonin uptake by an arylazido derivative of 5-hydroxytryptamine. Ransom RW, et al. **Mol Pharmacol** 1985 Aug; 28(2):185-90

Endogenous noradrenaline as modulator of hippocampal serotonin (5-HT)-release. Dual effects of yohimbine, rauwolscine and corynanthine as alpha-adrenoceptor antagonists and 5-HT-receptor agonists. Feuerstein TJ, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 May;329(3):216-21

Efflux of 3H-5-hydroxytryptamine from rat hypothalamic slices by continuous electrical stimulation: frequency-dependent responses to serotonergic antagonists and 5-hydroxytryptamine. Richards MH. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):359-66

Analysis of the heart rate effects of 5-hydroxytryptamine in the cat; mediation of tachycardia by 5-HT1-like receptors. Saxena PR, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug;330(2):121-9

Cyclic AMP facilitates the electrically evoked release of radiolabelled noradrenaline, dopamine and 5-hydroxytryptamine from rat brain slices. Schoffelmeer AN, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jul;330(1):74-6

Cardiovascular and sympathetic responses to intracarotid and intravenous injections of serotonin in rats. Takahashi H. **Naunyn Schmiedebergs Arch Pharmacol** 1985 May;329(3):222-6

Serotonin coexists with epinephrine in rat adrenal medullary cells. Holzwarth MA, et al. **Neuroendocrinology** 1985 Sep;41(3):230-6

Hypothalamic monoaminergic activity and pituitary function in male rats with estrogen-induced pituitary hyperplasia. Terry LC, et al. **Neuroendocrinology** 1985 Oct;41(4):269-75

Pharmacological studies on the serotoninergic and nonserotonin-mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L-tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283-8

Potentiation of motoneurone excitability by combined administration of 5-HT agonist and TRH analogue. Clarke KA, et al. **Neuropeptides** 1985 Jun;6(3):269-82

Increase in levels and ex vivo release of thyrotrophin-releasing hormone (TRH) in specific regions of the CNS of the rat by chronic treatment with antidepressants. Lighton C, et al. **Neuropharmacology** 1985 May; 24(5):401-6

Serotonin and norepinephrine-dependent effects of fenfluramine on plasma renin activity in conscious male rats. Van de Kar LD, et al. **Neuropharmacology** 1985 Jun;24(6):487-94

Intracerebroventricular administration of cholecystokinin inhibits the activity of the dopaminergic and serotoninergic systems of the brain. Vasar EE, et al. **Neurosci Behav Physiol** 1985 May-Jun;15(3).232-6

Dopaminergic toxicity after the stereotaxic administration of the 1-methyl-4-phenylpyridinium ion (MPP+) to rats. Heikkila RE, et al. **Neurosci Lett** 1985 Aug 16;59(1):135-40

A spinal projection of serotonergic neurons of the locus coeruleus in the cat. Lai YY, et al. **Neurosci Lett** 1985 Jul 31;58(2):159-64

Forebrain serotonergic involvement in avoidance learning. Ogren SO, et al. **Neurosci Lett** 1985 Aug 5;58(3):305-9

In vitro demonstration of dopamine uptake by neostriatal serotonergic neurons of the rat. Schmidt CJ, et al. **Neurosci Lett** 1985 Aug 16; 59(1):9-14

Ontogenesis of the central serotonin neuron system of the rat--an immunohistochemical study. Goto M, et al. **Neurosci Res** 1984 Feb; 1(1):3-18

Possible role of serotonin in the secretory activity of the subcommissural organ of the cat. Sakumoto T, et al. **Neurosci Res** 1984 Jun; 1(3):191-7

A facilitatory role for serotonin in the sexual behavior of the female rat. Mendelson SD, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):1025-33

Central serotonin neurones in avoidance learning: interactions with noradrenaline and dopamine neurones. Ogren SO. **Pharmacol Biochem Behav** 1985 Jul;23(1):107-23

Serotonin uptake and imipramine binding in rat platelets after chronic dexamethasone and amitriptyline treatment. Chan MY, et al. **Pharmacol Res Commun** 1985 Jul;17(7):619-32

Cholecystokinin-induced hypothermia: possible involvement of serotoninergic mechanisms in the rat hypothalamus. Liu HJ, et al. **Pharmacology** 1985;31(2):108-14

Transport systems and enzymes involved in the metamorphosis of tryptophan into serotonin. Baumann P. **Pharmacopsychiatry** 1985 Mar; 18(2):188-92

Anatomical features and physiological properties of central serotonin neurons. Baumgarten HG, et al. **Pharmacopsychiatry** 1985 Mar; 18(2):180-7

Serotonin involvement in lisuride-induced mounting and in sleep. Da Prada M, et al. **Pharmacopsychiatry** 1985 Mar;18(2):202-8

Receptor-mediated regulation of 5-hydroxytryptamine metabolism: current knowledge and open questions. Kehr W. **Pharmacopsychiatry** 1985 Mar;18(2):193-7

Significance of serotonin in central nervous functions. Maître L. **Pharmacopsychiatry** 1985 Mar;18(2):179

Human aggression and the role of central serotonin. Mühlbauer HD. **Pharmacopsychiatry** 1985 Mar;18(2):218-21

The importance of brain serotonergic receptor mechanisms for the action of antidepressant drugs. Ogren SO, et al. **Pharmacopsychiatry** 1985 Mar; 18(2):209-13

The 5-HT syndrome and the drug discrimination paradigm in rats: application in behavioral studies on the central 5-HT system. Ortmann R. **Pharmacopsychiatry** 1985 Mar;18(2):198-201

Serotonergic modulation of cortical rat noradrenergic system in the mechanism of action of antidepressant drugs. Brunello N, et al. **Psychopharmacol Bull** 1985;21(3):379-84

Persistent effects of amphetamine, p-chloroamphetamine, and related compounds on central dopamine and serotonin neurons in rodents. Fuller RW. **Psychopharmacol Bull** 1985;21(3):528-32

Serotonin-behavior interactions in vervet monkeys. McGuire MT, et al. **Psychopharmacol Bull** 1985;21(3):458-63

The serotonin/norepinephrine-linked beta-adrenoceptor system and the mode of action of antidepressants. Sanders-Bush E, et al. **Psychopharmacol Bull** 1985;21(3):373-8

Circadian variation in behavioural responses to central 5-HT receptor stimulation in the mouse. Moser PC, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):223-7

Ro 11-2465 (cyan-imipramine), citalopram and their N-desmethyl metabolites: effects on the uptake of 5-hydroxytryptamine and noradrenaline in vivo and related pharmacological activities. Pawlowski L, et al. **Psychopharmacology (Berlin)** 1985;86(1-2):156-63

Changes in human platelet 5 HT level after 1 week of chlorimipramine treatment. Poirier MF, et al. **Psychopharmacology (Berlin)** 1985; 86(1-2):194-6

Antidepressants and serotonergic neurotransmission: an integrative review. Willner P. **Psychopharmacology (Berlin)** 1985;85(4):387-404 (244 ref.)

The menstrual cycle and platelet 5-HT uptake. Tam WY, et al. **Psychosom Med** 1985 Jul-Aug;47(4):352-62

Synaptic arrangements formed by serotonin-immunoreactive axons in the substantia gelatinosa of the rat spinal cord. Maxwell DJ, et al. **Q J Exp Physiol** 1985 Jul;70(3):377-88

Hallucinogenic amphetamine selectively destroys brain serotonin nerve terminals. Ricaurte G, et al. **Science** 1985 Sep 6;229(4717):986-8

A strong influence of serotonin axons on beta-adrenergic receptors in rat brain. Stockmeier CA, et al. **Science** 1985 Oct 18; 230(4723):323-5

Effects of different anticoagulants on human platelet size distribution and serotonin (5-HT) induced shape change and uptake kinetics. Malmgren R, et al. **Thromb Res** 1985 Jun 15;38(6):649-61

Serotonin-binding protein: function in synaptic vesicles. Tamir H. **Trans NY Acad Sci** 1983;41:237-42

SEX BEHAVIOR, ANIMAL

Side effects of drugs stimulating prolactin secretion on the behavior of male rats. Drago F, et al. **Arch Int Pharmacodyn Ther** 1985 Aug; 276(2):271-8

Intrahypothalamic 5,7-dihydroxytryptamine: temporal analysis of effects on 5-hydroxytryptamine content in brain nuclei and on facilitated lordosis behavior. Frankfurt M, et al. **Brain Res** 1985 Aug 5; 340(1):127-33

GABAergic drugs and sexual behaviour in the male rat. Agmo A, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):371-8

A monoamine oxidase inhibitor reverses the 'separation syndrome' in a new hamster separation model of depression. Crawley JN. **Eur J Pharmacol** 1985 May 28;112(1):129-33

Prolactin influences sexual behavior during aging. Ferrara N, et al. **J Endocrinol Invest** 1985;8 Suppl 2:23-32

LHRH and mating behavior: sexual receptivity versus sexual preference. Dudley CA, et al. **Pharmacol Biochem Behav** 1985 Jun;22(6):967-72

A facilitatory role for serotonin in the sexual behavior of the female rat. Mendelson SD, et al. **Pharmacol Biochem Behav** 1985 Jun; 22(6):1025-33

Sexual excitement and stretching and yawning induced by B-HT 920. Ferrari F. **Pharmacol Res Commun** 1985 Jun;17(6):557-64

Serotonin involvement in lisuride-induced mounting and in sleep. Da

Prada M, et al. **Pharmacopsychiatry** 1985 Mar;18(2):202-8

Central muscarinic receptors and male rat sexual behavior: facilitation by oxotremorine but not arecoline or pilocarpine in methscopolamine pretreated animals. Ahlenius S, et al. **Psychopharmacology (Berlin)** 1985; 87(2):127-9

SLEEP

Changes in sleep EEG architecture during the treatment of depressed patients with mianserin. Mendlewicz J, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:26-9

Stress, catecholamines, and sleep. Harrison GA. **Aviat Space Environ Med** 1985 Jul;56(7):651-3

Central effects during the continuous osmotic infusion of a benzodiazepine (triazolam). Breimer DD, et al. **Br J Clin Pharmacol** 1985 Jun; 19(6):807-15

A microiontophoretic study of the actions of the putative sleep factor, piperidine, in the rat brainstem. Horton RC, et al. **Br J Pharmacol** 1985 May;85(1):37-44

The involvement of serotonin neurones in the inhibition of renal nerve activity during desynchronized sleep. Coote JH, et al. **Brain Res** 1985 Aug 12;340(2):277-84

Sleep and wake after benzodiazepine hypnotics: a 20-hour EEG comparison of lormetazepam and flunitrazepam. Timsit-Berthier M, et al. **Curr Med Res Opin** 1985;9(8):552-9

Route- and dose-dependent pharmacokinetics of hexobarbitone in the rat: a re-evaluation of the use of sleeping times in metabolic studies. Van der Graaff M, et al. **J Pharm Pharmacol** 1985 Aug;37(8):550-4

Simultaneous determination of blood levels of corticosterone and growth hormone in the male rat: relation to sleep-wakefulness cycle. Mitsugi N, et al. **Neuroendocrinology** 1985 Aug;41(2):125-30

Effects of alprazolam and diazepam on the daytime sleepiness of non-anxious subjects. Seidel WF, et al. **Psychopharmacology (Berlin)** 1985;87(2):194-7

[Action of clovoxamine on the sleep of depressed patients. 'Polygraphic recordings'] Minot R, et al. **Encephale** 1985 Mar-Apr;11(2):65-70 (Eng. Abstr.) **(Fre)**

SLEEP DEPRIVATION

Plasma renin activity and serum aldosterone during prolonged physical strain. The significance of sleep and energy deprivation. Opstad PK, et al. **Eur J Appl Physiol** 1985;54(1):1-6

Periodic sleep deprivation in drug-refractory depression. Dessauer M, et al. **Neuropsychobiology** 1985;13(3):111-6

Suppressant effect of REM sleep deprivation on neophobia in normal rats and in rats with selective DSP-4 induced damage of locus coeruleus neurons. Mogilnicka E, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):93-7

REM sleep deprivation effect on apomorphine-induced gnawing is reversed by dexamethasone. Nez L, et al. **Sleep** 1985;8(3):283-7

[Effect of 24-hour sleep deprivation on the metabolism of biogenic amines] Bol'shkova TD, et al. **Fiziol Cheloveka** 1985 Jul-Aug;11(4):652-6 **(Rus)**

SLEEP, REM

Superfusion of clomipramine within the ventromedial hypothalamus selectively suppresses paradoxical sleep in freely moving rats. Danguir J, et al. **Brain Res Bull** 1985 Jul;15(1):1-4

Brain noradrenergic activity in wakefulness and paradoxical sleep: the effect of clonidine. Gaillard JM. **Neuropsychobiology** 1985; 13(1-2):23-5

Suppressant effect of REM sleep deprivation on neophobia in normal rats and in rats with selective DSP-4 induced damage of locus coeruleus neurons. Mogilnicka E, et al. **Pharmacol Biochem Behav** 1985 Jul; 23(1):93-7

REM sleep deprivation effect on apomorphine-induced gnawing is reversed by dexamethasone. Nez L, et al. **Sleep** 1985;8(3):283-7

SLEEP STAGES

Reversal of slow-wave sleep by benzodiazepine antagonist Ro 15-1788 [letter] Ziegler G, et al. **Lancet** 1985 Aug 31;2(8453):510

Serotonin involvement in lisuride-induced mounting and in sleep. Da Prada M, et al. **Pharmacopsychiatry** 1985 Mar;18(2):202-8

Effects of alprazolam and diazepam on the daytime sleepiness of non-anxious subjects. Seidel WF, et al. **Psychopharmacology (Berlin)** 1985;87(2):194-7

SOCIAL ADJUSTMENT

Planned change: an innovative nursing rehabilitation model. Bevvino CA, et al. **Perspect Psychiatr Care** 1984 Oct-Dec;22(4):149-58

Social skills training for patients with schizophrenia: a controlled clinical trial. Wallace CJ, et al. **Psychiatry Res** 1985 Jul;15(3):239-47

SODIUM

Transepithelial cation movements in gerbil utricles. Marcus NY, et al. **Am J Otolaryngol** 1985 Jul-Aug;6(4):268-74

Intracellular mediators of Na+-K+ pump activity in guinea pig pancreatic acinar cells. Hootman SR, et al. **Am J Physiol** 1985 Oct; 249(4 Pt 1):G470-8

Sodium dependence of luminal alkalinization by rabbit ileal mucosa. Smith PL, et al. **Am J Physiol** 1985 Sep;249(3 Pt 1):G358-68

Adrenergic-agonist-induced Ca2+ fluxes in rat parotid cells are not Na+-dependent. Helman J, et al. **Biochem J** 1985 Sep 1; 230(2):313-20

Effects of ATP and cyclic AMP on the (Na+ + K+ + 2Cl-)-cotransport system in turkey erythrocytes. Ueberschär S, et al. **Biochim Biophys Acta** 1985 Aug 27;818(2):260-6

In vitro dopamine biosynthesis in the median eminence of rat hypothalamic slices: possible involvement of a Na+-Ca2+ exchange mechanism. Arita J, et al. **Brain Res** 1985 Jul 15;338(2):384-6

Influence of the extracellular ionic environment on ganglionic fast excitatory postsynaptic currents. Connor EA, et al. **Brain Res** 1985 Jul 29;339(2):227-35

Sodium-independent binding of [3H]cocaine in mouse striatum is serotonin related. Reith ME, et al. **Brain Res** 1985 Sep 2;342(1):145-8

Effects of thermal adaptation at 40 degrees C on membrane viscosity and the sodium-potassium pump in Chinese hamster ovary cells. Bates DA, et al. **Cancer Res** 1985 Oct;45(10):4895-9

Effect of hypophysectomy on plasma electrolytes and adrenal mineralocorticoid secretion in the terrestrial chelonian Testudo hermanni. Vallarino M, et al. **Comp Biochem Physiol [A]** 1985; 81(2):283-6

The characterization of a sodium-dependent high affinity choline uptake system unassociated with acetylcholine biosynthesis. Ivy MT, et al. **Comp Biochem Physiol [C]** 1985;81(2):351-7

Sodium and proton transport in Mycoplasma gallisepticum. Linker C, et al. **J Bacteriol** 1985 Sep;163(3):1250-7

Reconstitution and purification of the sodium- and chloride-coupled gamma-aminobutyric acid transporter from rat brain. Radian R, et al. **J Biol Chem** 1985 Sep 25;260(21):11859-65

Reconstitution of a bacterial Na+/H+ antiporter. Seto-Young D, et al. **J Biol Chem** 1985 Sep 25;260(21):11393-5

Effects of ketanserin on the intracellular concentration and transmembrane fluxes of sodium and potassium in erythrocytes of normal male subjects. Lijnen P, et al. **J Cardiovasc Pharmacol** 1985;7 Suppl 7:S38-40

Characterization of a BALB/c 3T3 preadipose cell mutant with altered Na+K+Cl- cotransport activity. Sussman I, et al. **J Cell Physiol** 1985 Jul;124(1):153-9

Isotachophoresis as a candidate reference method in analytical chemistry. Determination of sodium in serum. Lemmens AA, et al. **J Chromatogr** 1985 Feb 22;320(1):193-7

Control of sodium and potassium transport in the cortical collecting duct of the rat. Effects of bradykinin, vasopressin, and deoxycorticosterone. Tomita K, et al. **J Clin Invest** 1985 Jul;76(1):132-6

Removal of sodium channel inactivation in squid axon by the oxidant chloramine-T. Wang GK, et al. **J Gen Physiol** 1985 Aug; 86(2):289-302

Effect of metabolic depletion on the furosemide-sensitive Na and K fluxes in human red cells. Dagher G, et al. **J Membr Biol** 1985; 86(2):145-55

Effects of stimulation and diphenylhydantoin on the intracellular sodium activity in Purkinje fibres of sheep heart. Ellis D. **J Physiol (Lond)** 1985 May;362:331-48

The dependence of the salt appetite of the rat on the hormonal consequences of sodium deficiency. Epstein AN. **J Physiol (Paris)** 1984; 79(6):496-8

Acute effects of hemodialysis on erythrocyte sodium fluxes in uremic patients. Quarello F, et al. **Nephron** 1985;41(1):22-5

Sodium-dependent, calmodulin-dependent transmitter release from synaptosomes. Sandoval ME, et al. **Neurosci Lett** 1985 May 23; 56(3):271-7

[Changes in cerebral calcium, sodium and potassium after single or repeated administration of lithium in the rat] Scotto di Tella AM, et al. **Encephale** 1985 Mar-Apr;11(2):53-6 (Eng. Abstr.) **(Fre)**

[Role of the kallikrein-kinin system and prostaglandins in the action of dopamine on blood flow and sodium transport in the rat kidney] Kuz'min OB, et al. **Fiziol Zh SSSR** 1985 May;71(5):619-24 (Eng. Abstr.) **(Rus)**

[Effect of Na+, K+ and Ca++ ions on catecholamine release in the caudal mesenteric ganglion] Reprintseva VM. **Fiziol Zh SSSR** 1985 May; 71(5):561-8 (Eng. Abstr.) **(Rus)**

SOMATOSTATIN

Plasma growth hormone (GH) and somatomedin C response to continuous growth hormone-releasing factor (GRF) infusion in patients with GH deficiency. Hizuka N, et al. **Acta Endocrinol (Copenh)** 1985 Sep; 110(1):17-23

BIBLIOGRAPHY

Thyrotrophin-releasing hormone (TRH) and hormone secretion from the follicular and C-cells of perfused dog thyroid lobes. Iversen E, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):499-504

Dual inhibitory actions of somatostatin on isolated gastric glands. Nylander O, et al. **Acta Physiol Scand** 1985 Sep;125(1):111-9

Somatostatin. Proceedings of a satellite symposium of the Seventh International Congress of Endocrinology. June 29-30, 1984, Montreal, Quebec. **Adv Exp Med Biol** 1985;188:1-524

Somatostatin-28 [1-12]-like peptides. Benoit R, et al. **Adv Exp Med Biol** 1985;188:89-107

Central nervous system actions of somatostatin-related peptides. Brown MR, et al. **Adv Exp Med Biol** 1985;188:217-28

Proteolytic events in the post-translational processing of somatostatin precursors from rat brain cortex and anglerfish pancreatic islets. Cohen P, et al. **Adv Exp Med Biol** 1985;188:109-21

Somatostatin agonists and antagonists--peptide control of growth hormone secretion. Coy DH, et al. **Adv Exp Med Biol** 1985; 188:325-37

Somatostatins of the channel catfish. Dixon JE, et al. **Adv Exp Med Biol** 1985;188:19-29

Immunocytochemical studies of somatostatin neurons in brain. Elde R, et al. **Adv Exp Med Biol** 1985;188:167-81

Biosynthesis of rat preprosomatostatin. Goodman RH, et al. **Adv Exp Med Biol** 1985;188:31-47

Distribution and morphology of somatostatin cells. Larsson LI. **Adv Exp Med Biol** 1985;188:383-402

Post-translational processing of anglerfish islet somatostatin precursors. Noe BD, et al. **Adv Exp Med Biol** 1985;188:123-40

Somatostatin-14 like immunoreactive forms in the rat: characterization, distribution and biosynthesis. Patel YC, et al. **Adv Exp Med Biol** 1985; 188:71-87

Somatostatin secretion from the hypothalamus. Peterfreund RA, et al. **Adv Exp Med Biol** 1985;188:183-200

Regulation and actions of gastrointestinal somatostatin. Pittenger GL, et al. **Adv Exp Med Biol** 1985;188:447-62

Mechanisms of somatostatin action in pituitary cells. Schonbrunn A, et al. **Adv Exp Med Biol** 1985;188:305-24

Expression of anglerfish preprosomatostatin genes in mammalian cells: studies on the synthesis and post-translational processing of somatostatin precursors. Shields D, et al. **Adv Exp Med Biol** 1985;188:3-18

The effects of somatostatin and selected analogs on lipid absorption in animals. Slater EE, et al. **Adv Exp Med Biol** 1985;188:355-68

Anglerfish pancreatic islets produce two forms of somatostatin-28. Spiess J, et al. **Adv Exp Med Biol** 1985;188:141-54

Somatostatin receptors. Srikant CB, et al. **Adv Exp Med Biol** 1985; 188:291-304

Physiological role of somatostatin in regulation of pulsatile growth hormone secretion. Tannenbaum GS. **Adv Exp Med Biol** 1985; 188:229-59 (119 ref.)

Approaches to the study of somatostatin biosynthesis. Zingg HH, et al. **Adv Exp Med Biol** 1985;188:49-58

Effect of GRP on beta-adrenergic-stimulated gastrin and somatostatin release in the isolated rat stomach. Short GM, et al. **Am J Physiol** 1985 Aug;249(2 Pt 1):G197-202

Mode of action of somatostatin to inhibit secretion by shark rectal gland. Silva P, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):R329-34

Somatostatin and peripheral blood flow in man. Savi L, et al. **Angiology** 1985 Aug;36(8):511-5

Partial retro-inverso analogues of somatostatin: pairwise modifications at residues 7 and 8 and at residues 8 and 9. Pallai PV, et al. **Biochemistry** 1985 Apr 9;24(8):1933-41

Localization by immunoelectron microscopy of somatostatin-containing cells in the gastric mucosa of a teleost fish, Perca fluviatilis. Noaillac-Depeyre J. **Biol Cell** 1985;53(3):263-7

Somatostatin binding sites in cytosolic fractions of parietal and non-parietal cells from rabbit fundic mucosa. Arilla E, et al. **Biosci Rep** 1985 Apr;5(4):321-8

Growth hormone secretion and pancreatic function following somatostatin infusion in ducks (Anas platyrhynchos). Strosser MT, et al. **Br Poult Sci** 1985 Jul;26(3):425-32

Ultrastructural morphometric analysis of somatostatin-like immunoreactive neurones in the rat central nervous system after labelling with colloidal gold. Foster GA, et al. **Brain Res** 1985 Sep 2;342(1):117-27

The development of somatostatin immunoreactivity in the interpeduncular nucleus of the cat. Morley BJ, et al. **Brain Res** 1985 Jun; 352(2):241-8

Interrelationships between somatostatin-like cells and other endocrine cells in the pancreas of some cartilaginous fish. Tagliafierro G, et al. **Cell Mol Biol** 1985;31(3):201-7

The half-life of endogenous insulin and C-peptide in man assessed by somatostatin suppression. Matthews DR, et al. **Clin Endocrinol (Oxf)** 1985 Jul;23(1):71-9

Somatostatin binding sites in cytosolic fraction of rabbit intestinal mucosa: distribution throughout the intestinal tract. López-Ruiz MP, et al. **Comp Biochem Physiol [B]** 1985;81(4):1041-4

Effect of glucagon antibodies on plasma glucose, insulin and somatostatin in the fasting and fed rat. Tan K, et al. **Diabetologia** 1985 Jul; 28(7):435-40

The effect of pancreatic acinar atrophy upon the concentration of vasoactive intestinal polypeptide, substance P, somatostatin and glucagon in the pancreas and gastrointestinal tract of the rat. Ballmann M, et al. **Digestion** 1985;32(1):70-5

Effect of simultaneous infusion of a somatostatin analogue, insulin and glucose on serum triglycerides and blood glucose levels in man. Fukushima H, et al. **Endocrinol Jpn** 1985 Apr;32(2):241-8

Stimulation of somatostatin release in vitro by synthetic human growth hormone-releasing factor by a nondopaminergic mechanism. Aguila MC, et al. **Endocrinology** 1985 Aug;117(2):762-5

Internalization and cellular processing of somatostatin in primary culture of rat anterior pituitary cells. Draznin B, et al. **Endocrinology** 1985 Sep; 117(3):960-6

Effects of rat growth hormone (rGH)-releasing factor and somatostatin on the release and synthesis of rGH in dispersed pituitary cells. Fukata J, et al. **Endocrinology** 1985 Aug;117(2):457-67

Modulation of somatostatin binding to rat pituitary membranes by exogenously administered growth hormone. Katakami H, et al. **Endocrinology** 1985 Aug;117(2):557-60

Hypothalamic somatostatin mediates the suppression of growth hormone secretion by centrally administered thyrotropin-releasing hormone in conscious rats. Katakami H, et al. **Endocrinology** 1985 Sep; 117(3):1139-44

Somatostatin-like material is present in flowering plants. LeRoith D, et al. **Endocrinology** 1985 Nov:117(5):2093-7

Prolonged inhibition of growth hormone secretion by peripheral injection of bombesin is mediated by somatostatin in the rat. Murphy WA, et al. **Endocrinology** 1985 Sep;117(3):1179-83

Effects of intracellular glucopenia on pulsatile growth hormone secretion: mediation in part by somatostatin. Painson JC, et al. **Endocrinology** 1985 Sep;117(3):1132-8

Pantethine, a cysteamine precursor, depletes immunoreactive somatostatin and prolactin in the rat. Reichlin S, et al. **Endocrinology** 1985 Aug; 117(2):492-5

The effects of growth hormone, prolactin, corticotropin, and thyrotropin on the production and secretion of somatostatin by hypothalamic cells in vitro. Robbins RJ, et al. **Endocrinology** 1985 Aug;117(2):538-43

Somatostatin metabolism by the isolated rat lung. Ruggere MD, et al. **Endocrinology** 1985 Nov;117(5):1870-3

Cellular distribution of insulin, glucagon, pancreatic polypeptide hormone and somatostatin in the fetal and adult pancreas of the guinea pig: a comparative immunohistochemical study. Reddy SN, et al. **Eur J Cell Biol** 1985 Sep;38(2):301-5

Blood pressure following microinjection of somatostatin related peptides into the rat nucleus tractus solitarii. Koda LY, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):425-30

Phorbol esters affect pituitary growth hormone (GH) and prolactin release: the interaction with GH releasing factor, somatostatin and bromocriptine. Summers ST, et al. **Eur J Pharmacol** 1985 May 20; 111(3):371-6

Somatostatin-like immunoreactivity in the pituitary and brain of three teleost fish species: somatostatin as a potential regulator of prolactin cell function. Grau EG, et al. **Gen Comp Endocrinol** 1985 Sep; 59(3):350-7

Autonomic regulation of postprandial plasma somatostatin, gastrin, and insulin. Lucey MR, et al. **Gut** 1985 Jul;26(7):683-8

DNA synthesis in lactotrophs of primary rat anterior pituitary cell cultures. Effects of thyroliberin, bromocriptine and somatostatin. Komolov IS, et al. **Histochemistry** 1985;82(5):497-500

Islet isolation from atrophied pancreas after short-term duct ligature--evidence for normal in vitro release of insulin and somatostatin. Bodziony J, et al. **Horm Metab Res** 1985 Jun; 17(6):314-6

Hexapeptide analogue of somatostatin, Sandoz 201-456. Conformational study in dimethylsulfoxide by 1D and 2D n.m.r. methods. Wynants C, et al. **Int J Pept Protein Res** 1985 Jun;25(6):622-7

SMS 201-995, a very potent analogue of somatostatin. Assignment of the 1H 500 MHz n.m.r. spectra and conformational analysis in aqueous solution. Wynants C, et al. **Int J Pept Protein Res** 1985 Jun; 25(6):608-14

SMS 201-995, an octapeptide somatostatin analogue. Assignment of the 1H 500 MHZ n.m.r. spectra and conformational analysis of SMS 201-995 in dimethylsulfoxide. Wynants C, et al. **Int J Pept Protein Res** 1985 Jun;25(6):615-21

Effects of dopamine and morphine on immunoreactive somatostatin and LH-releasing hormone secretion from hypothalamic fragments in vitro. Lengyel AM, et al. **J Endocrinol** 1985 Sep;106(3):317-22

Effect of somatostatin and thyrotrophin-releasing hormone on the levels of growth hormone in the circulation of the chronically catheterized pig fetus in utero. Spencer GS, et al. **J Endocrinol** 1985 Jul; 106(1):121-4

Somatostatin precursor in the rat striatum: changes after local injection of kainic acid. Sperk G, et al. **J Neurochem** 1985 Nov;45(5):1441-7

Effect of somatostatin on the zona glomerulosa of rats treated with angiotensin II or captopril: stereology and plasma hormone concentrations. Mazzocchi G, et al. **J Steroid Biochem** 1985 Sep; 23(3):353-6

Is somatostatin a directly acting cholestatic hormone? Schirmer BD, et al. **J Surg Res** 1985 Sep;39(3):237-45

Vagal modulation of arginine- and glucagon-induced pancreatic somatostatin secretion. Seino Y, et al. **Life Sci** 1985 Aug 19; 37(7):651-6

Amino acids release somatostatin-like immunoreactivity from isolated rat glomeruli. Fujibayashi S, et al. **Mol Cell Endocrinol** 1985 Jul; 41(2-3):263-7

Different patterns of molecular forms of somatostatin are released by the rat median eminence and hypothalamus. Pierotti AR, et al. **Neurosci Lett** 1985 Jun 24;57(3):215-20

Actions of somatostatin on lipid metabolism in mouse cerebral cortex slices. Catalán RE, et al. **Neurosci Res** 1985 Feb;2(3):201-4

Primary explants as a model of the hypothalamus in situ. Baldino F Jr, et al. **Peptides (Fayetteville)** 1985 Mar-Apr;6(2):249-56

The localization and origin of somatostatin-containing fibers in an auditory brainstem nucleus. Morley BJ. **Peptides (Fayetteville)** 1985; 6 Suppl 1:165-72

Somatostatin mediates the effect of growth hormone surges on splanchnic biogenic amines. Hussain MN, et al. **Proc Soc Exp Biol Med** 1985 Sep; 179(4):517-21

The kidney growth in animals treated with somatostatin. Polić L, et al. **Przegl Lek** 1985;42(4):436-8

Somatostatin and intestinal calcium transport in the rat. Rümenapf G, et al. **Regul Pept** 1985 Aug;11(4):299-308

Pharmacological effects of gastric inhibitory polypeptide, cholecystokinin, and somatostatin on the serum levels of cationic trypsin-like immunoreactivity in man. Florholmen J, et al. **Scand J Gastroenterol** 1985 Sep;20(7):829-34

Release of gastrointestinal regulatory peptides after a soap enema. Jenssen TG, et al. **Scand J Gastroenterol** 1985 Aug;20(6):762-6

Antramine (antral histamine) antagonizes somatostatin inhibition on endogenous gastrin-induced gastric secretion. A new hypothesis for the role of histamine in gastric secretion regulation. Vatier J, et al. **Scand J Gastroenterol** 1985 Aug;20(6).671-6

Patterns of growth hormone-releasing factor and somatostatin secretion into the hypophysial-portal circulation of the rat. Plotsky PM, et al. **Science** 1985 Oct 25;230(4724):461-3

Plasma secretin, pancreozymin, and somatostatin-like hormone in chronic renal failure patients. Grekas DM, et al. **Uremia Invest** 1984-85; 8(2):117-20

[Hormone-producing (paracrine) cells in the human labyrinth] Arnold W, et al. **Laryngol Rhinol Otol (Stuttg)** 1985 Jul;64(7):359-63 (Eng. Abstr.) (Ger)

SOMATOTROPIN RELEASING HORMONE

Effects of in vivo gonadal hormone environment on in vitro hGRF-40-stimulated GH release. Evans WS, et al. **Am J Physiol** 1985 Sep;249(3 Pt 1):E276-80

Growth hormone responses to growth hormone releasing factor in neonates. Shimano S, et al. **Biol Neonate** 1985;47(6):367-70

Immunoreactive neuronal pathways of growth hormone-releasing hormone (GRH) in the brain and pituitary of the teleost Gadus morhua. Pan JX, et al. **Cell Tissue Res** 1985;241(3):487-93

Effects on growth hormone secretion following intravenous and subcutaneous injections of growth hormone-releasing factor (hGRF-44 NH2): comparison of immunoreactive plasma GRF levels. Sassolas G, et al. **Clin Endocrinol (Oxf)** 1985 May;22(5):645-53

Growth hormone, thyrotropin and prolactin responses to simultaneous administration of human growth hormone-releasing factor and thyrotropin releasing hormone in the bovine. Hodate K, et al. **Endocrinol Jpn** 1985 Jun;32(3):375-83

Plasma GH and somatomedin C responses to single and repeated administrations of human growth hormone releasing factor (hGRF). Takano K, et al. **Endocrinol Jpn** 1985 Feb;32(1):73-80

Plasma growth hormone and somatomedin-C responses to continuous growth hormone-releasing factor infusion in normal adult men. Takano K, et al. **Endocrinol Jpn** 1985 Apr;32(2):287-93

Stimulation of somatostatin release in vitro by synthetic human growth hormone-releasing factor by a nondopaminergic mechanism. Aguila MC, et al. **Endocrinology** 1985 Aug;117(2):762-5

Immunoreactive and biologically active growth hormone-releasing factor in the rat placenta. Baird A, et al. **Endocrinology** 1985 Oct; 117(4):1598-601

Presence of growth hormone-releasing factor-like immunoreactivity in rat duodenum. Bruhn TO, et al. **Endocrinology** 1985 Oct; 117(4):1710-2

Effects of rat growth hormone (rGH)-releasing factor and somatostatin on the release and synthesis of rGH in dispersed pituitary cells. Fukata J, et al. **Endocrinology** 1985 Aug;117(2):457-67

Involvement of growth hormone-releasing factor in growth hormone secretion induced by gamma-aminobutyric acid in conscious rats. Murakami Y, et al. **Endocrinology** 1985 Aug;117(2):787-9

Structural requirements for the activation of rat anterior pituitary adenylate cyclase by growth hormone-releasing factor (GRF): discovery of (N-Ac-Tyr1, D-Arg2)-GRF(1-29)-NH2 as a GRF antagonist on membranes. Robberecht P, et al. **Endocrinology** 1985 Nov; 117(5):1759-64

Phorbol esters affect pituitary growth hormone (GH) and prolactin release: the interaction with GH releasing factor, somatostatin and bromocriptine. Summers ST, et al. **Eur J Pharmacol** 1985 May 20; 111(3):371-6

Variability of GH response to GRF shows no relationship with peripheral somatostatin and somatomedin C levels. Plewe G, et al. **Horm Metab Res** 1985 Sep;17(9):481

Effect of acute intravenous growth hormone-releasing factor on plasma prolactin in short children and patients with growth hormone deficiency. Chatelain PG, et al. **Horm Res** 1985;22(1-2):46-51

Effects of intravenous, subcutaneous, and intranasal administration of growth hormone (GH)-releasing hormone-40 on serum GH concentrations in normal men. Evans WS, et al. **J Clin Endocrinol Metab** 1985 Nov;61(5):846-50

Effects of pulsatile administration of growth hormone (GH)-releasing hormone on short term linear growth in children with GH deficiency. Gelato MC, et al. **J Clin Endocrinol Metab** 1985 Sep;61(3):444-50

The distribution of growth-hormone-releasing factor (GRF) immunoreactivity in the central nervous system of the rat: an immunohistochemical study using antisera directed against rat hypothalamic GRF. Sawchenko PE, et al. **J Comp Neurol** 1985 Jul 1;237(1):100-15

Growth hormone response to growth hormone-releasing factor in selected and control Holstein heifer calves. Massri YG, et al. **J Dairy Sci** 1985 Jul;68(7):1819-21

Effects of a fragment of human growth hormone-releasing factor in normal and 'Little' mice. Clark RG, et al. **J Endocrinol** 1985 Jul; 106(1):1-5

Growth hormone responses to multiple injections of a fragment of human growth hormone-releasing factor in conscious male and female rats. Clark RG, et al. **J Endocrinol** 1985 Sep;106(3):281-9

Coexistence of growth hormone releasing factor-like and tyrosine hydroxylase-like immunoreactivities in neurons of the rat arcuate nucleus. Okamura H, et al. **Neuroendocrinology** 1985 Aug; 41(2):177-9

Pituitary secretion of growth hormone in response to opioid peptides and opiates is mediated through growth hormone-releasing factor. Wehrenberg WB, et al. **Neuroendocrinology** 1985 Jul;41(1):13-6

Immunohistochemical demonstration of a new neurone system in rat brain using antibodies against human growth hormone-releasing factor (1-37). Fellmann D, et al. **Neurosci Lett** 1985 Jul 4;58(1):91-6

Patterns of growth hormone-releasing factor and somatostatin secretion into the hypophysial-portal circulation of the rat. Plotsky PM, et al. **Science** 1985 Oct 25;230(4724):461-3

SPATIAL BEHAVIOR

Facilitation of spontaneous and learned spatial behaviours following 6-hydroxydopamine lesions of the lateral septum: a cholinergic hypothesis. Galey D, et al. **Brain Res** 1985 Aug 5;340(1):171-4

STARTLE REACTION

Cocaine: excitatory effects on sensorimotor reactivity measured with acoustic startle. Davis M. **Psychopharmacology (Berlin)** 1985; 86(1-2):31-6

Effects of 8-OH-DPAT, lisuride and some ergot-related compounds on the acoustic startle response in the rat. Svensson L. **Psychopharmacology (Berlin)** 1985;85(4):469-75

STEREOTYPED BEHAVIOR

Effects of single and repeated application of clonazepam and diazepam combined with cyproheptadine on apomorphine stereotypy in rats. Georgiev VP, et al. **Agressologie** 1985 Jan;26(1):57-60

Clonidine sensitizes mice for apomorphine-induced stereotypic gnawing: antagonism by neuroleptics and cholecystokinin-like peptides. Zetler G. **Eur J Pharmacol** 1985 May 20;111(3):309-18

Influence of phenoxybenzamine on the stereotyped behaviour induced by fencamfamine in rats: evidence for a qualitative alteration. Bernardi MM, et al. **Gen Pharmacol** 1985;16(4):403-5

Effect of ergometrine on methamphetamine and apomorphine stereotypy in the guinea-pig. Balsara JJ, et al. **J Pharm Pharmacol** 1985 Jul; 37(7):514-7

Sensitization to stress: the enduring effects of prior stress on amphetamine-induced rotational behavior. Robinson TE, et al. **Life Sci** 1985 Sep 16;37(11):1039-42

Antistereotypic effects of dopamine D-1 and D-2 antagonists after intrastriatal injection in rats. Pharmacological and regional specificity. Arnt J. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Aug; 330(2):97-104

Central nervous system effect of 2,5-hexane diol. Agrawal AK, et al. **Neurotoxicology** 1985 Fall;6(3):53-9

Lidocaine kindling is accompanied by an increase in apomorphine stereotypy and mesolimbic dopamine D2 receptor density. Csernansky JG, et al. **Psychopharmacol Bull** 1985;21(3):707-11

The comparative long-term effects of ciladopa (AY-27,110), a chemically novel dopaminergic agonist, in 6-OHDA-lesioned and intact rats. Voith K. **Psychopharmacology (Berlin)** 1985;85(4):405-9

[Effect of 2 new GABA-ergic agents on apomorphine stereotypy in the rat] Vamvakidès A. **Agressologie** 1985 Jan;26(1):63-5 (Eng. Abstr.) **(Fre)**

[Effect of arachidonic acid on stereotyped behavior in the rabbit induced by a dopamine receptor agonist] Kurchikov AL, et al. **Zh Vyssh Nerv Deiat** 1985 Jul-Aug;35(4):783-5 **(Rus)**

STRESS, PSYCHOLOGICAL

Biological stress responses in high and low trait anxious students. Davis DD, et al. **Biol Psychiatry** 1985 Aug;20(8):843-51

Beta-adrenoceptor responsiveness and plasma catecholamines as determinants of cardiovascular reactivity to mental stress. Eisenhofer G, et al. **Clin Sci** 1985 Oct;69(4):483-92

Stress-induced elevation of plasma alpha-MSH and endorphin in brown trout, Salmo trutta L. Sumpter JP, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):257-65

Behaviorally equivalent stressors differentially modify the monoamine altering property of d-amphetamine. Klauenberg BJ, et al. **Pharmacol Biochem Behav** 1985 Sep;23(3):417-23

Plasma adrenaline and noradrenaline during mental stress and isometric exercise in man. The role of arterial sampling. Jörgensen LS, et al. **Scand J Clin Lab Invest** 1985 Sep;45(5):447-52

[Stress and the excretion of catecholamines in patients after kidney transplantation] Honzák R, et al. **Cas Lek Cesk** 1985 Jul 19; 124(29):912-3 (Eng. Abstr.) **(Cze)**

[Modification of psychic, autonomic and metabolic reactions during examinations by a single dose of beta-receptor blockers] Pietruschka WD, et al. **Z Gesamte Inn Med** 1985 May 15;40(10):289-92 (Eng. Abstr.) **(Ger)**

[Dopamine beta-hydroxylase activity in the plasma of women as an indicator of perioperative stress] Zrubek H, et al. **Ginekol Pol** 1984 Nov;55(11):859-62 (Eng. Abstr.) **(Pol)**

[Role of the adrenergic system in the pathomechanism of functional disorders in puberty] Szewczyk L. **Pediatr Pol** 1985 Apr;60(4):300-5 (Eng. Abstr.) **(Pol)**

[Immunological aspects of surgical stress] Gadalov VP. **Anesteziol Reanimatol** 1985 May-Jun;(3):69-72 (103 ref.) **(Rus)**

[Changes in the adrenal medulla of the rat during immobilization stress] Shvalev VN, et al. **Arkh Anat Gistol Embriol** 1985 Aug; 89(8):97-102 (Eng. Abstr.) **(Rus)**

SUBSTANCE P

Blockade of substance P receptors inhibits non-nicotinic, non-adrenergic colonic contractions induced by stimulation of the lumbar sympathetic nerves to the feline large intestine. Fändriks L, et al. **Acta Physiol Scand** 1985 Aug;124(4):565-71

Pharmacological analysis of the mechanism of action for colonic contraction induced by neurotensin, substance P and methionine-enkephalin. Hellström PM. **Acta Physiol Scand** 1985 Sep; 125(1):13-24

Cholecystokinin inhibits binding of substance P to pancreatic acinar cells. Sjödin L. **Acta Physiol Scand** 1985 Jul;124(3):471-4

Some effects of substance P on central respiratory control in rabbit pups. Yamamoto Y, et al. **Acta Physiol Scand** 1985 Jul;124(3):449-55

High-affinity substance P binding sites in rat sympathetic ganglia. Niwa M, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):H694-7

Substance P and 5-hydroxytryptamine immunoreactive presynaptic boutons on presumed alpha-motoneurons in the chicken ventral horn. Atsumi S, et al. **Arch Histol Jpn** 1985 Apr;48(2):159-72

Substance P-like immunoreactive nerves in the human eye. Stone RA, et al. **Arch Ophthalmol** 1985 Aug;103(8):1207-11

Dopamine-mediated increases in nigral substance P-like immunoreactivity. Ritter JK, et al. **Biochem Pharmacol** 1985 Sep 1; 34(17):3161-6

Analysis of the mechanism of histamine release induced by substance P. Shibata H, et al. **Biochim Biophys Acta** 1985 Jul 30;846(1):1-7

CSF substance P immunoreactivity in affective disorders. Berrettini WH, et al. **Biol Psychiatry** 1985 Sep;20(9):965-70

Evidence for the existence of substance P in the prepubertal rat ovary. II. Immunocytochemical localization. Dees WL, et al. **Biol Reprod** 1985 Sep;33(2):471-6

Evidence for the existence of substance P in the prepubertal rat ovary. I. Biochemical and physiologic studies. Ojeda SR, et al. **Biol Reprod** 1985 Sep;33(2):286-95

The regional distribution of kassinin-like immunoreactivity in central and peripheral tissues of the cat. Hunter JC, et al. **Brain Res** 1985 Aug 26;341(2):228-32

Increase in substance P in the dorsal horn during a chemogenic nociceptive stimulus. Kantner RM, et al. **Brain Res** 1985 Jul 8; 338(1):196-9

LH-RH analogue acts as substance P antagonist by inhibiting spinal cord vasomotor responses. Takano Y, et al. **Brain Res** 1985 Jul 1; 337(2):357-61

Prostaglandins enhance trigeminal substance P-ergic responses in the rabbit iris sphincter muscles. Ueda N, et al. **Brain Res** 1985 Jul 1; 337(2):347-51

Localization of substance P-like, leucine-enkephalin-like, methionine-enkephalin-like, and FMRFamide-like immunoreactivity in the eyestalk of the fiddler crab, Uca pugilator. Fingerman M, et al. **Cell Tissue Res** 1985;241(3):473-7

Substance P-immunoreactive neurons in the brainstem of the cat related to cardiovascular centers. Triepel J, et al. **Cell Tissue Res** 1985; 241(1):31-41

The effect of pancreatic acinar atrophy upon the concentration of vasoactive intestinal polypeptide, substance P, somatostatin and glucagon in the pancreas and gastrointestinal tract of the rat. Ballmann M, et al. **Digestion** 1985;32(1):70-5

Effects of substance P and substance P-(6-11) on hormone release from isolated perfused pancreas: their opposite actions on rat and canine islets. Chiba Y, et al. **Endocrinology** 1985 Nov;117(5):1996-2000

Age-, sex-, and gonadal steroid-related changes in immunoreactive substance P in the rat anterior pituitary gland. DePalatis LR, et al. **Endocrinology** 1985 Oct;117(4):1368-73

Inhibition of substance P degradation in rat brain preparations by peptide hydroxamic acids. Laufer R, et al. **Eur J Biochem** 1985 Jul 1; 150(1):135-40

Both substance P agonists and antagonists inhibit ion conductance through nicotinic acetylcholine receptors on PC12 cells. Eardley D, et al. **Eur J Pharmacol** 1985 Aug 7;114(1):101-4

Tachykinin responses in the rat cingulate cortex: a comparison of the effects of iontophoretically applied substance P and neurokinin A. Jones RS, et al. **Eur J Pharmacol** 1985 Sep 10;115(1):113-6

Effects of the substance P antagonist [D-Arg1,D-Pro2,D-Trp7,9,Leu11]SP on miosis caused by echothiophate iodide or pilocarpine hydrochloride. Mandahl A. **Eur J Pharmacol** 1985 Aug 15;114(2):121-7

Progabide reverses the nigral substance P reduction induced by chronic impairment of dopaminergic transmission. Zivkovic B, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):253-5

Immunoreactive substance P and LH-RH content in median eminence and pituitary gland during proestrus, oestrus, lactation and after anterior hypothalamic deafferentation. Jakubowska-Naziemblo B, et al. **Exp Clin Endocrinol** 1985 Apr;85(2):155-66

Effects of analogues of substance P fragments on the MAO activity in rat brain. Turska E, et al. **Gen Pharmacol** 1985;16(3):293-5

Neurokinin A-like immunoreactivity in rat primary sensory neurons; coexistence with substance P. Dalsgaard CJ, et al. **Histochemistry** 1985; 83(1):37-9

Substance P-like immunoreactivity in adrenal chromaffin cells and intra-adrenal nerve fibers of rats. Kuramoto H, et al. **Histochemistry** 1985;82(6):507-12

Anti-substance P anti-idiotypic antibodies. Characterization and biological activities. Couraud JY, et al. **J Biol Chem** 1985 Aug 5; 260(16):9461-9

Characterization of an immunofluorescence technique for the demonstration of coexisting neurotransmitters within nerve fibers and terminals. Wessendorf MW, et al. **J Histochem Cytochem** 1985 Oct; 33(10):984–94

Conformationally restricted C–terminal peptides of substance P. Synthesis, mass spectral analysis and pharmacological properties. Theodoropoulos D, et al. **J Med Chem** 1985 Oct;28(10):1536–9

On the nature of the contractile motor responses of the rat stomach elicited by serotonin or substance P in vitro. Lidberg P, et al. **J Neural Transm** 1985;63(1):73–89

Presence and ontogeny of enkephalin and substance P in the chick ciliary ganglion. White JD, et al. **J Neurochem** 1985 Oct;45(4):1319–22

Properties of choroid and ciliary neurons in the avian ciliary ganglion and evidence for substance P as a neurotransmitter. Dryer SE, et al. **J Neurosci** 1985 Oct;5(10):2654–61

Enzyme–linked immunosorbent assay of substance P and its metabolite SP 1–7. A comparison with RIA. Folkesson R, et al. **J Neurosci Methods** 1985 Aug;14(3):169–76

Altered respiratory response to substance P in capsaicin–treated rats. Towle AC, et al. **J Neurosci Res** 1985;14(2):239–53

Evidence against VIP or substance P being the transmitter in non–cholinergic excitatory nerves supplying the guinea–pig bladder. Meldrum LA, et al. **J Pharm Pharmacol** 1985 Jun;37(6):432–4

Substance P provoked gamma–aminobutyric acid release from the myenteric plexus of the guinea–pig small intestine. Tanaka C, et al. **J Physiol (Lond)** 1985 May;362:319–29

Possible influence of tachykinins on body fluid homeostasis in the rat. Cantalamessa F, et al. **J Physiol (Paris)** 1984;79(6):524–30

Catabolism of substance P in the stomach wall of the rat. Bunnett NW, et al. **Life Sci** 1985 Aug 19;37(7):599–606

Substance P antagonists and mucociliary activity in rabbit. Lindberg S, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):376–81

Multiple tachykinin receptors in guinea pig brain. High densities of substance K (neurokinin A) binding sites in the substantia nigra. Quirion R, et al. **Neuropeptides** 1985 Jun;6(3):191–204

Neuronal sensitivity to substance P is increased after repeated treatment with tranylcypromine, carbamazepine or oxaprotaline, but decreased after repeated electroconvulsive shock. Jones RS, et al. **Neuropharmacology** 1985 Jul;24(7):627–33

Co–localization of calcitonin gene–related peptide–like immunoreactivity with substance P in cutaneous, vascular and visceral sensory neurons of guinea pigs. Gibbins IL, et al. **Neurosci Lett** 1985 Jun 12; 57(2):125–30

Substance K and substance P in the ventral tegmental area. Kalivas PW, et al. **Neurosci Lett** 1985 Jun 24;57(3):241–6

Immunocytochemical localization of substance P in the rat spinal cord with special reference to fibers within the ventral column of the rostral lumbar segments. Uda K, et al. **Neurosci Lett** 1985 Jun 12; 57(2):185–90

Regional distribution of substance P, neurokinin alpha and neurokinin beta in rat central nervous system. Kanazawa I, et al. **Neurosci Res** 1984 Dec;2(1–2):111–20

Distribution of calcitonin gene–related peptide in the rat peripheral nervous system with reference to its coexistence with substance P. Lee Y, et al. **Neuroscience** 1985 Aug;15(4):1227–37

Substance P–containing sensory nerves in the rat iris. Normal distribution, ontogeny and innervation of intraocular iris grafts. Seiger A, et al. **Neuroscience** 1985 Jun;15(2):519–28

Substance P given intrathecally at the spinal T9 level increases adrenal output of adrenaline and noradrenaline in the rat. Yashpal K, et al. **Neuroscience** 1985 Jun;15(2):529–36

Catabolism of gastrin releasing peptide and substance P by gastric membrane–bound peptidases. Bunnett NW, et al. **Peptides (Fayetteville)** 1985 Mar–Apr;6(2):277–83

Capsaicin reduces substance P immunoreactivity in the lateral nucleus of the solitary tract and nodose ganglion. Helke CJ, et al. **Peptides (Fayetteville)** 1985;6 Suppl 1:121–6

Precursor forms of substance P (SP) in nervous tissue: detection with antisera to SP, SP–Gly, and SP–Gly–Lys. Kream RM, et al. **Proc Natl Acad Sci USA** 1985 Jul;82(14):4832–6

Guanine nucleotides regulate [3H]substance P binding in rat small intestine. Smith KE, et al. **Regul Pept** 1985 Aug;11(4):275–85

Verapamil inhibition of the intestinal effects of substance P. Zinner MJ, et al. **Surgery** 1985 Aug;98(2):230–5

Effects of dopamine and substance P infusion on gastric acid secretion in Pavlov and Heidenhain pouched dogs. Ogoshi K, et al. **Tokai J Exp Clin Med** 1984 Aug;9(3):183–90

[Capillary isotachophoresis––a new method in drug analysis. 2. Analytical capillary isotachophoresis of the synthetic peptide substance P] Jannasch R. **Pharmazie** 1985 Jun;40(6):398–403 (Eng. Abstr.) **(Ger)**

[Substance P in the central mechanisms of the escape reaction] Zilov VG, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):6–8 (Eng. Abstr.) **(Rus)**

SUCKING BEHAVIOR

Histidyl–proline–diketopiperazine (cyclo–his–pro) inhibits the suckling– and domperidone–induced transformation of prolactin in the lactating rat. Shyr SW, et al. **Endocrinology** 1985 Nov;117(5):2170–5

SYMPATHOMIMETICS

Effect of gastrin, histamine, serotonin, and adrenergic amines on gastroesophageal sphincter pressure in the dog. Strombeck DR, et al. **Am J Vet Res** 1985 Aug;46(8):1684–90

Beta 1–adrenoceptor selectivity and intrinsic sympathomimetic activity [letter] De Bono GG. **Br J Clin Pharmacol** 1985 Jul;20(1):92

Intrinsic sympathomimetic activity of cardioselective beta–adrenoceptor blockers and effects on renal function. Mackay IG, et al. **Br J Clin Pharmacol** 1985 Sep;20(3):197–203

Effects of adrenergic agonists and cyclic AMP on the short–circuit current across the isolated rabbit iris–ciliary body. Chu TC, et al. **Curr Eye Res** 1985 Apr;4(4):523–9

[The problem of the characterization of butoxamine as a specific antagonist of the metabolic effects of sympathomimetics] Ankermann H. **Biomed Biochim Acta** 1985;44(4):645–8 **(Ger)**

[Effect of cholino– and adrenomimetic substances on B–lymphocyte proliferation in mice during a primary immune response to a protein antigen] Ado AD, et al. **Biull Eksp Biol Med** 1985 Jul;100(7):46–8 (Eng. Abstr.) **(Rus)**

[Interaction of beta–adrenergic agents with the plasma membranes of the myocardium] Chekman IS, et al. **Biull Eksp Biol Med** 1985 Aug; 100(8):208–10 (Eng. Abstr.) **(Rus)**

SYNAPTIC RECEPTORS

Blockade of substance P receptors inhibits non–nicotinic, non–adrenergic colonic contractions induced by stimulation of the lumbar sympathetic nerves to the feline large intestine. Fändriks L, et al. **Acta Physiol Scand** 1985 Aug;124(4):565–71

High–affinity substance P binding sites in rat sympathetic ganglia. Niwa M, et al. **Am J Physiol** 1985 Sep;249(3 Pt 2):H694–7

Displacement of DL–[3H]–2–amino–4–phosphonobutanoic acid ([3H]APB) binding with methyl–substituted APB analogues and glutamate agonists. Robinson MB, et al. **Biochemistry** 1985 May 7; 24(10):2401–5

Selective effects of thiol reagents on the binding sites for imipramine and neurotransmitter amines in the rat brain. Biassoni R, et al. **Br J Pharmacol** 1985 Jun;85(2):447–56

A specific alkylating ligand for phencyclidine (PCP) receptors antagonizes PCP behavioral effects. Contreras PC, et al. **Eur J Pharmacol** 1985 May 20;111(3):405–6

Phencyclidine and sigma opiate receptors in brain: biochemical and autoradiographical differentiation. Gundlach AL, et al. **Eur J Pharmacol** 1985 Jul 31;113(3):465–6

Blocking action of pentobarbital on receptors for excitatory amino acids in the guinea pig hippocampus. Sawada S, et al. **Exp Brain Res** 1985; 59(2):226–31

Pharmacology of neuroleptics in use in the United States. Richelson E. **J Clin Psychiatry** 1985 Aug;46(8 Pt 2):8–14

Elevated density of [3H]imipramine binding in aged human brain. Severson JA, et al. **J Neurochem** 1985 Nov;45(5):1382–9

Multiple tachykinin receptors in guinea pig brain. High densities of substance K (neurokinin A) binding sites in the substantia nigra. Quirion R, et al. **Neuropeptides** 1985 Jun;6(3):191–204

Amitriptylinoxide: receptor–binding profile compared with other antidepressant drugs. Borbe HO, et al. **Pharmacopsychiatry** 1985 Sep; 18(5):314–9

Diazepam administration to mice prevents some of the changes in monoamine–mediated behaviour produced by repeated electroconvulsive shock treatment. Green AR, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):190–3

Guanine nucleotides regulate [3H]substance P binding in rat small intestine. Smith KE, et al. **Regul Pept** 1985 Aug;11(4):275–85

[Effect of chronic psychogenic stress on the characteristics of synaptic membrane receptors in the rat brain] Nikuradze VO, et al. **Biull Eksp Biol Med** 1985 Sep;100(9):275–7 (Eng. Abstr.) **(Rus)**

[Autoradiographic study of the ontogeny of the imipramine receptors in the cerebral cortex of rats] Pirogova MV, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):752–4 (Eng. Abstr.) **(Rus)**

[Mechanism of the modulating effect of met–enkephalin on glutamatergic synaptic transmission] Kuznetsov VI, et al. **Dokl Akad Nauk SSSR** 1985; 282(2):456–9 **(Rus)**

TESTOSTERONE

Selective and/or overlapping effect of pituitary hormones (thyrotropin, gonadotropin) on serum thyroxin and testosterone level in newly hatched cockerels. Dobozy O, et al. **Acta Physiol Hung** 1985; 66(2):177–81

Reversal of the sexually dimorphic distribution of serotonin–immunoreactive fibers in the medial preoptic nucleus by treatment with perinatal androgen. Simerly RB, et al. **Brain Res** 1985 Aug 5;340(1):91–8

Plasma testosterone and catecholamine responses to physical exercise of different intensities in men. Ježová D, et al. **Eur J Appl Physiol** 1985; 54(1):62–6

Testosterone and melatonin effects on adrenal cortex of orchiectomized and pinealectomized rats. Malendowicz LK, et al. **Exp Clin Endocrinol** 1985 Jun;85(3):283–8

Seasonal cycles in testicular activity, gonadotropin, and thyroxine in the painted turtle, Chrysemys picta, under natural conditions. Licht P, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):130–9

Effect of intraventricular injection of 5,6–dihydroxytryptamine on spermatogenesis and plasma testosterone levels in the rat. Das TK, et al. **J Endocrinol** 1985 Sep;106(3):395–400

Testosterone secretion is severely impaired after hepatectomy in rat, dog and man. Sultan C, et al. **J Steroid Biochem** 1985 Jun;22(6):851–3

Effects of delta 9–tetrahydrocannabinol on testosterone production in vitro: influence of Ca++, Mg++ or glucose. Dalterio S, et al. **Life Sci** 1985 Oct 14;37(15):1425–33

Intratesticular regulation of testosterone secretion: comparison of the effects and interactions of hCG, an LHRH agonist and testicular interstitial fluid on Leydig cell testosterone secretion in vitro. Sharpe RM. **Mol Cell Endocrinol** 1985 Jul;41(2–3):247–55

Further studies on the effects of testosterone on hypothalamic LH–RH and serum LH levels: castration–induced delayed response. Kalra PS. **Neuroendocrinology** 1985 Sep;41(3):219–23

THIORIDAZINE

Thioridazine: a selective inhibitor of peroxisomal beta–oxidation in vivo. Van den Branden C, et al. **FEBS Lett** 1985 Aug 5;187(2):331–3

Phenolic metabolites of thioridazine in man. Papadopoulos AS, et al. **Xenobiotica** 1985 Apr;15(4):309–16

[A case of agranulocytosis during treatment with thioridazine] Tuma I, et al. **Cesk Psychiatr** 1985 Apr;81(2):106–9 (Eng. Abstr.) **(Cze)**

THIRST

The effect of captopril on sodium appetite in adrenalectomized and deoxycorticosterone–treated rats. Elfont RM, et al. **J Physiol (Lond)** 1985 Aug;365:1–12

Side–effects of lithium at lower therapeutic levels: the significance of thirst. King JR, et al. **Psychol Med** 1985 May;15(2):355–61

THYROID HORMONES

Relationship between thyroid hormone and body fat in young Japanese. Nakashima T, et al. **Ann Physiol Anthropol** 1984 Apr;3(2):129–31

Thyroid–dependent maturation of neonatal brain but not lung epidermal growth factor receptors. Sadiq HF, et al. **Dev Pharmacol Ther** 1985; 8(5):292–301

Thyroid hormones in rats during long–term cold exposure and hypometabolic effect of reverse triiodothyronine on adrenaline induced thermogenesis. Vybiral S, et al. **Endocrinol Exp (Bratisl)** 1985 Sep; 19(3):179–85

Effects of thyroid hormone deficiency on glial constituents in developing cerebellum of the rat. Granholm AC. **Exp Brain Res** 1985; 59(3):451–6

5'–Flanking DNA of the rat growth hormone gene mediates regulated expression by thyroid hormone. Casanova J, et al. **J Biol Chem** 1985 Sep 25;260(21):11744–8

Role of thyroid function on CNS regeneration. Tator CH. **J Neurosurg Sci** 1984 Jul–Dec;28(3–4):133–5

[Modulation of thyroid hormone synthesis by thyroglobulin] Lissitzky S. **Bull Acad Natl Med (Paris)** 1985 Feb;169(2):261–6 (Eng. Abstr.) **(Fre)**

[Structure and function of thyroid follicular cells––biochemical and histochemical studies on the enzymes related to thyroid hormone synthesis] Matsubara F. **Rinsho Byori** 1985 Apr;33(4):406–20 **(Jpn)**

[Hormonal regulation of anabolic processes and of protein utilization efficiency in the early postnatal period] Adigamov LF, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):687–9 (Eng. Abstr.) **(Rus)**

THYROTROPIN

Effects of eledoisin on thyrotrophin secretion in rats. Mitsuma T, et al. **Acta Endocrinol (Copenh)** 1985 Sep;110(1):90–4

Selective and/or overlapping effect of pituitary hormones (thyrotropin, gonadotropin) on serum thyroxin and testosterone level in newly hatched cockerels. Dobozy O, et al. **Acta Physiol Hung** 1985; 66(2):177–81

Effect of thyrotropin (TSH) treatment on the vitamins A and E and lipid–peroxide status of domestic fowl. Mézes M. **Acta Vet Hung** 1984; 32(3–4):175–80

A novel method of transport for thyroxine (T4), cortisol, thyroid stimulating hormone (TSH), parathormone (PTH), and insulin. Ch'ng SL, et al. **Clin Chim Acta** 1985 Jul 15;149(2–3):253–6

Growth hormone, thyrotropin and prolactin responses to simultaneous administration of human growth hormone–releasing factor and thyrotropin releasing hormone in the bovine. Hodate K, et al. **Endocrinol Jpn** 1985 Jun;32(3):375–83

The effects of growth hormone, prolactin, corticotropin, and thyrotropin on the production and secretion of somatostatin by hypothalamic cells in vitro. Robbins RJ, et al. **Endocrinology** 1985 Aug;117(2):538–43

Effects of TRH and a rat TSH preparation on discrete hypothalamic and forebrain catecholamine nerve terminal networks in the hypophysectomized male rat. Andersson K, et al. **Eur J Pharmacol** 1985 May 20;111(3):295–307

Physalaemin inhibits thyrotropin secretion in rats. Mitsuma T, et al. **Exp Clin Endocrinol** 1985 Jun;85(3):319–25

Thyroid function in adult rough–skinned newts (Taricha granulosa): effects of hypophysectomy and hormone replacement. Specker JL, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):326–31

Effects of various drugs on thyrotropin secretion in rats. Mitsuma T, et al. **Horm Metab Res** 1985 Jul;17(7):337–41

Association of the changes in cytosolic Ca2+ and iodide efflux induced by thyrotropin and by the stimulation of alpha 1–adrenergic receptors in cultured rat thyroid cells. Corda D, et al. **J Biol Chem** 1985 Aug 5;260(16):9230–6

Thyroid indices in panic disorder. Fishman SM, et al. **J Clin Psychiatry** 1985 Oct;46(10):432–3

Effect of immunoneutralization of thyrotrophin–releasing hormone on the release of thyrotrophin and prolactin during suckling or in response to electrical stimulation of the hypothalamus in the anaesthetized rat. Sheward WJ, et al. **J Endocrinol** 1985 Jul;106(1):113–9

Comparison of the ability of thyroxine and triiodothyronine to suppress TRH–induced TSH secretion by perfused rat anterior pituitary fragments. Ikeda H, et al. **Neuroendocrinology** 1985 Jul;41(1):79–82

A nonmitogenic pituitary function of fibroblast growth factor: regulation of thyrotropin and prolactin secretion. Baird A, et al. **Proc Natl Acad Sci USA** 1985 Aug;82(16):5545–9

[Effect of dopaminergic pharmacological agents on thyrotropic hormone secretion by the hypophysis when stimulated with thyrotropin–releasing hormone] Boiadzhieva N, et al. **Eksp Med Morfol** 1985;24(1):29–32 (Eng. Abstr.) **(Bul)**

[Serum thyroxine and thyrotropin in the elderly] Mattila KS, et al. **Duodecim** 1985;101(14):1375–9 (Eng. Abstr.) **(Fin)**

THYROXINE

Post–natal thyroid function in low birth weight infants; a longitudinal assessment of free thyroxine and thyroid hormone binding globulin. Hirano T, et al. **Acta Endocrinol (Copenh)** 1985 Sep;110(1):56–60

Thyrotrophin–releasing hormone (TRH) and hormone secretion from the follicular and C–cells of perfused dog thyroid lobes. Iversen E, et al. **Acta Endocrinol (Copenh)** 1985 Aug;109(4):499–504

Acquisition of urine, kidney and submandibular gland epidermal growth factor responsiveness to thyroxine administration in neonatal mice. Lakshmanan J, et al. **Acta Endocrinol (Copenh)** 1985 Aug; 109(4):511–6

Selective and/or overlapping effect of pituitary hormones (thyrotropin, gonadotropin) on serum thyroxin and testosterone level in newly hatched cockerels. Dobozy O, et al. **Acta Physiol Hung** 1985; 66(2):177–81

Management of a child with acute thyroxine ingestion. Roesch C, et al. **Ann Emerg Med** 1985 Nov;14(11):1114–5

Thyroxine bioequivalency [letter] **Ann Intern Med** 1985 Oct; 103(4):646–7

A novel method of transport for thyroxine (T4), cortisol, thyroid stimulating hormone (TSH), parathormone (PTH), and insulin. Ch'ng SL, et al. **Clin Chim Acta** 1985 Jul 15;149(2–3):253–6

Minimal metabolism, summit metabolism and plasma thyroxine in rodents from different environments. Hulbert AJ, et al. **Comp Biochem Physiol** [A] 1985;81(3):687–93

Protein utilization in growth: effect of lysine deficiency on serum growth hormone, somatomedins, insulin, total thyroxine (T4) and triiodothyronine, free T4 index, and total corticosterone. Cree TC, et al. **Endocrinology** 1985 Aug;117(2):667–73

Evidence for induction by thyroid hormone of cytosolic proteins which control mitochondrial protein synthesis. Ichikawa K, et al. **Endocrinology** 1985 Nov;117(5):1749–58

Seasonal cycles in testicular activity, gonadotropin, and thyroxine in the painted turtle, Chrysemys picta, under natural conditions. Licht P, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):130–9

Immunofluorescent detection and localization of thyroxine in blood of Rana catesbeiana from early larval through metamorphic stages. Piotrowski DC, et al. **Gen Comp Endocrinol** 1985 Jul;59(1):82–90

Thyroid function in adult rough–skinned newts (Taricha granulosa): effects of hypophysectomy and hormone replacement. Specker JL, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):326–31

Thyroid indices in panic disorder. Fishman SM, et al. **J Clin Psychiatry** 1985 Oct;46(10):432–3

An enzyme–linked immunosorbent assay for thyroxine in dried blood spotted on filter paper. Maeda M, et al. **J Immunol Methods** 1985 Sep 3;82(1):83–9

Thyroxine analogue assay kits in clinical medicine [letter] **Lancet** 1985 Oct 5;2(8458):781–2

Binding protein variation and free thyroxine assay, and effect of venous stasis [letter] France NC, et al. **Lancet** 1985 Oct 5;2(8458):782–3

Free thyroxine assays: analogue methods [letter] Wilkins TA. **Lancet** 1985 Oct 19;2(8460):884

Cerebral myelinogenesis in the Snell dwarf mouse: stimulatory effects of GH and T4 restricted to the first 20 days of postnatal life. Sugisaki T, et al. **Neurochem Res** 1985 Jun;10(6):767–78

Neonatal levels of plasma thyroxine in male and female calves fed a colostrum or immunoglobulin diet or fasted for the first 28 hours of life. Grongnet JF, et al. **Reprod Nutr Dev** 1985;25(3):537–43

[Serum thyroxine and thyrotropin in the elderly] Mattila KS, et al. **Duodecim** 1985;101(14):1375–9 (Eng. Abstr.) **(Fin)**

[Action of thyroxine on the cytochrome content in the brain and liver mitochondria during the postnatal development of rats] Khamidov DKh, et al. **Biull Eksp Biol Med** 1985 Jun;99(6):696–7 (Eng. Abstr.) **(Rus)**

[Correlation between the thyroxine, 17–beta–estradiol and luteinizing hormones in the systemic circulation and the rectal and vaginal temperature in heifers and cows after administration of cloprostenol] Elečko J, et al. **Vet Med (Praha)** 1985 May;30(5):257–66 (Eng. Abstr.) **(Slo)**

TIME PERCEPTION

[Schizophrenically disordered time perception and its modification by neuroleptics] Heim M, et al. **Psychiatr Neurol Med Psychol (Leipz)** 1985 Jul;37(7):410–5 (Eng. Abstr.) **(Ger)**

TRANQUILIZING AGENTS

[Treatment of vegetovascular dystonia with beta–blockaders and tranquilizers] Zubarev IuG, et al. **Sov Med** 1985;(3):82–5 **(Rus)**

[Development of passivity in the rat: effect of tranquilizers and antidepressants] Khonicheva NM, et al. **Zh Vyssh Nerv Deiat** 1985 Mar–Apr;35(2):339–47 (Eng. Abstr.) **(Rus)**

[Hypo–salivation and tranquilizers] Montana Ramonet JM. **Rev Esp Estomatol** 1984 Nov–Dec;32(6):407–20 **(Spa)**

TRANQUILIZING AGENTS, MAJOR

An open multicentre study of the treatment of florid schizophrenia with remoxipride. McCreadie RG, et al. **Acta Psychiatr Scand** 1985 Aug; 72(2):139–43

A treatment trial with an analog of thyrotropin–releasing hormone (DN–1417) in schizophrenia. Mizuki Y, et al. **Biol Psychiatry** 1985 Sep; 20(9):1030–5

Neuroleptics, lithium and renal function. Waller DG, et al. **Br J Psychiatry** 1985 May;146:510–4

Prediction of response to neuroleptic drug therapy in schizophrenia. Awad AG. **Can J Psychiatry** 1985 Jun;30(4):241–2

Early subjective response and prediction of outcome to neuroleptic drug therapy in schizophrenia. Hogan TP, et al. **Can J Psychiatry** 1985 Jun; 30(4):246–8

Clinical and demographic correlates of neuroleptic response. Seeman MV. **Can J Psychiatry** 1985 Jun;30(4):243–5

Prediction of treatment response in schizophrenia: clinical use of neuroleptic blood levels. Tang SW. **Can J Psychiatry** 1985 Jun; 30(4):249–50

Long–acting neuroleptics: technique for intramuscular injection. Bélanger–Annable MC. **Can Nurse** 1985 Sep;81(8):41–3

In vitro thiomethylation. Studies with flumezapine. Sullivan HR, et al. **Drug Metab Dispos** 1985 May–Jun;13(3):276–8

Multidimensional study of the outcome of schizophrenic patients 1 year after clinic discharge. Predictors and influence of neuroleptic treatment. Gaebel W, et al. **Eur Arch Psychiatry Neurol Sci** 1985;235(1):45–52

Interaction of SCH 23390, a D–1–selective antagonist, with the anterior pituitary D–2 receptors and prolactin secretion in the rat. Apud JA, et al. **Eur J Pharmacol** 1985 Jun 7;112(2):187–93

SCH–23390 antagonism of a D–2 dopamine agonist depends upon catecholaminergic neurons. Breese GR, et al **Eur J Pharmacol** 1985 Jul 11;113(1):109–14

Antagonism of the amphetamine cue by both classical and atypical antipsychotic drugs. Nielsen EB, et al. **Eur J Pharmacol** 1985 May 8; 111(2):167–76

Antipsychotic drugs depress acetylcholine release in the Torpedo electric organ, a purely cholinergic system. Schaller–Clostre F, et al. **Eur J Pharmacol** 1985 May 28;112(1):27–37

Effects of iminodibenzyl antipsychotic drugs on cerebral dopamine and alpha–adrenergic receptors. Setoguchi M, et al. **Eur J Pharmacol** 1985 Jun 19;112(3):313–22

Clonidine sensitizes mice for apomorphine–induced stereotypic gnawing: antagonism by neuroleptics and cholecystokinin–like peptides. Zetler G. **Eur J Pharmacol** 1985 May 20;111(3):309–18

Differential effects of some predominantly antiadrenergic and antidopaminergic neuroleptics on the preovulatory surge of FSH, LH and prolactin in rat. Kun I, et al. **Exp Clin Endocrinol** 1985 Jun; 85(3):269–75

Relationship between gas chromatographic behaviour and topological, physicochemical, and quantum chemically calculated charge parameters for neuroleptica. Buydens L, et al. **J Chromatogr Sci** 1985 Jul; 23(7):304–7

Antipsychotic or neuroleptic? [letter] Dove MJ. **J Clin Psychiatry** 1985 Oct;46(10):454–5

Pharmacology of neuroleptics in use in the United States. Richelson E. **J Clin Psychiatry** 1985 Aug;46(8 Pt 2):8–14

Neuroleptic drug monitoring and radioreceptor assays [editorial] Cooper TB. **J Clin Psychopharmacol** 1985 Oct;5(5):A15–6

The strategy and value of neuroleptic drug monitoring. Curry SH. **J Clin Psychopharmacol** 1985 Oct;5(5):263–71 (56 ref.)

On the clinical relevance and methods of quantification of plasma concentrations of neuroleptics. Ko GN, et al. **J Clin Psychopharmacol** 1985 Oct;5(5):253–62 (49 ref.)

Mesolimbic dopamine function is not altered during continuous chronic treatment of rats with typical or atypical neuroleptic drugs. Rupniak NM, et al. **J Neural Transm** 1985;62(3–4):249–66

Binding of [3H]SCH23390 in rat brain: regional distribution and effects of assay conditions and GTP suggest interactions at a D1–like dopamine receptor. Schulz DW, et al. **J Neurochem** 1985 Nov;45(5):1601–11

Dopamine D2 receptors selectively labeled by a benzamide neuroleptic: [3H]–YM–09151–2. Niznik HB, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1985 Jun;329(4):333–43

Electrophysiological interactions between haloperidol and reduced haloperidol, and dopamine, norepinephrine and phencyclidine in rat brain. Kirch DG, et al. **Neuropharmacology** 1985 May;24(5):375–9

The effect of milenperone on the aggressive behavior of psychogeriatric patients. A double–blind placebo–controlled study. De Cuyper H, et al. **Neuropsychobiology** 1985;13(1–2):1–6

A rapid and simple behavioural screening method for simultaneous assessment of limbic and striatal blocking effects of neuroleptic drugs. Ljungberg T, et al. **Pharmacol Biochem Behav** 1985 Sep; 23(3):479–85

Discriminative stimulus properties and schedule effects of fencamfamine in rats. Risner ME, et al. **Pharmacol Biochem Behav** 1985 Sep; 23(3):449–56

Distribution and excretion of 3H–dapiprazole in the rat. Valeri P, et al. **Pharmacol Res Commun** 1985 May;17(5):417–24

High–dose versus low–dose strategies in the treatment of schizophrenia. Kane JM, et al. **Psychopharmacol Bull** 1985;21(3):533–7

Effect of neuroleptic treatments on attention, information processing, and thought disorder. Spohn HE, et al. **Psychopharmacol Bull** 1985; 21(3):582–7

An open study of remoxipride, a benzamide derivative, in schizophrenia. Lindström L, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):241–3

Negative and deficit symptoms in schizophrenia do respond to neuroleptics. Goldberg SC. **Schizophr Bull** 1985;11(3):453–6

Informed consent in psychiatric research: preliminary findings from an ongoing investigation. Benson PR, et al. **Soc Sci Med** 1985; 20(12):1331–41

[Changes in the CSF levels of monoamine metabolites in 102 chronic schizophrenic patients following probenecid before and after neuroleptic medication] Chen YF. **Chung Hua Shen Ching Ching Shen Ko Tsa Chih** 1984 Oct; 17(5):273–7 (Eng. Abstr.) **(Chi)**

[Administration of maintenance therapy in endogenous psychoses in out–patient practice] Mrňa B, et al. **Cesk Psychiatr** 1985 Aug; 81(4):273–5 (Eng. Abstr.) **(Cze)**

[Clinical effectiveness of isofloxythepin––an open study] Zapletálek M, et al. **Cesk Psychiatr** 1985 Aug;81(4):242–6 (Eng. Abstr.) **(Cze)**

[Technics for intramuscular injections of delayed–action neuroleptics] Bélanger–Annable MC. **Infirm Can** 1985 Sep;27(8):26–9 **(Fre)**

[A study on application of the function of maintaining concentration (TAF) for chronic schizophrenia] Okamoto Y, et al. **Hokkaido Igaku Zasshi** 1985 May;60(3):445–9 (Eng. Abstr.) **(Jpn)**

[Neuroleptics in pregnancy (letter)] Karniol IG, et al. **Rev Paul Med** 1985 Jan–Feb;103(1):46 **(Por)**

[Effect of neurotropic drugs on calmodulin and troponin C–dependent processes] Baldenkov GN, et al. **Biokhimiia** 1985 Jul;50(7):1141–50 (Eng. Abstr.) **(Rus)**

[Effect of carbidine on the dopamine and serotonin receptors of the central nervous system] Zharkovskii AM, et al. **Biull Eksp Biol Med** 1985 Jun; 99(6):700–2 (Eng. Abstr.) **(Rus)**

[Malignant hyperthermia caused by neuroleptics] Escolano Villén F, et al. **Rev Esp Anestesiol Reanim** 1985 Jul–Aug;32(4):189–91 (Eng. Abstr.) **(Spa)**

TRANQUILIZING AGENTS, MINOR

Depression and anxiety: mianserin and nomifensine compared in a double–blind multicentre trial. Granier F, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:67–74

Chronic anxiolytic treatment: benefit and risk. Marks J. **Adv Biochem Psychopharmacol** 1985;40:173–83

Selective interaction of novel anxiolytics with 5–hydroxytryptamine1A receptors. Peroutka SJ. **Biol Psychiatry** 1985 Sep;20(9):971–9

The psychological effects of buspirone. Bond A. **Br J Clin Pract [Symp Suppl]** 1985 May;38:83–90

The pharmacological treatment of anxiety. Jenner FA, et al. **Br J Clin Pract [Symp Suppl]** 1985 May;38:48–52

Clinical profile of buspirone. Knapp JE. **Br J Clin Pract [Symp Suppl]** 1985 May;38:95–9

The risk of pharmacological dependence with buspirone. Tyrer P, et al. **Br J Clin Pract [Symp Suppl]** 1985 May;38:91–4

Buspirone: a new type of anxiolytic. Dommisse CS, et al. **Drug Intell Clin Pharm** 1985 Sep;19(9):624–8 (28 ref.)

The non-sedating anxiolytic CGS 9896 produces discriminative stimuli that may be related to an anxioselective effect. Bennett DA. **Life Sci** 1985 Aug 26;37(8):703–9

Metoprolol, a new selective beta-blocker in anxiety neurosis. Chaturvedi SK. **Psychopharmacology (Berlin)** 1985;85(4):488

Studies on the suanzaorentang in the treatment of anxiety. Chen HC, et al. **Psychopharmacology (Berlin)** 1985;85(4):486–7

Midazolam cue in rats: generalization tests with anxiolytic and other drugs. Garcha HS, et al. **Psychopharmacology (Berlin)** 1985;87(2):233–7

The effects of compounds related to gamma-aminobutyrate and benzodiazepine receptors on behavioural responses to anxiogenic stimuli in the rat: choice behaviour in the T-maze. Quintero S, et al. **Psychopharmacology (Berlin)** 1985;86(3):328–33

TRANYLCYPROMINE

Neuronal sensitivity to substance P is increased after repeated treatment with tranylcypromine, carbamazepine or oxaprotaline, but decreased after repeated electroconvulsive shock. Jones RS, et al. **Neuropharmacology** 1985 Jul;24(7):627–33

TRIAZOLAM

Comment: Triazolam-cimetidine reaction [letter] Greenblatt DJ. **Drug Intell Clin Pharm** 1985 Sep;19(9):679

Pharmacokinetic consequences of long term coadministration of cimetidine and triazolobenzodiazepines, alprazolam and triazolam, in healthy subjects. Pourbaix S, et al. **Int J Clin Pharmacol Ther Toxicol** 1985 Aug;23(8):447–51

Effects of diazepam and triazolam on auditory and visual thresholds and reaction times in the baboon. Lukas SE, et al. **Psychopharmacology (Berlin)** 1985;87(2):167–72

[Further data on the detection of triazolam (Halcion) and its main metabolites] Schütz H. **Beitr Gerichtl Med** 1985;43:465–7 (Eng. Abstr.) **(Ger)**

TRIFLUOPERAZINE

Inhibitors of calcium-dependent enzymes prevent the onset of afterdischarge in the peptidergic bag cell neurons of Aplysia. DeRiemer SA, et al. **Brain Res** 1985 Aug 5;340(1):175–80

Effect of trifluoperazine on DNA synthesis during liver regeneration. Soriano M, et al. **Cell Tissue Kinet** 1985 Sep;18(5):475–81

Modulation of the digestive lysosomal system in Paramecium caudatum. II. Physiological effects of cytochalasin B, colchicine and trifluoperazine. Fok AK, et al. **Eur J Cell Biol** 1985 May;37:27–34

Crystallization of calcium-calmodulin-trifluoperazine complex and an attempt at crystallizing calcium-free calmodulin. Kawasaki H, et al. **J Biochem (Tokyo)** 1985 Jun;97(6):1815–8

Effects of trifluoperazine on calcium binding by calmodulin. A microcalorimetric study. Tanokura M, et al. **J Biol Chem** 1985 Jul 25; 260(15):8680–2

Inhibition of epidermal growth factor-induced phosphorylation by trifluoperazine. Ross AH, et al. **J Cell Physiol** 1985 Sep; 124(3):499–506

Prostaglandin output from the early pregnant rat uterus superfused in vitro, and the effect of A23187 and trifluoperazine. Poyser NL. **J Reprod Fertil** 1985 May;74(1):271–7

Effects of discontinuous drug administration on the development of dopamine receptor supersensitivity during chronic trifluoperazine or cis-flupenthixol administration to rats. Murugaiah K, et al. **Psychopharmacology (Berlin)** 1985;86(1–2):228–32

Studies on the effect of platelet inhibitors on platelet adhesion to collagen and collagen-induced human platelet activation. Krishnamurthi S, et al. **Thromb Haemost** 1985 Jun 24;53(3):337–42

Effects of trifluoperazine on platelet activation. Ardlie NG, et al. **Thromb Res** 1985 Jun 15;38(6):695–706

TRIMEPRAZINE

Radioimmunoassay for trimeprazine in human plasma. McKay G, et al. **J Pharmacol Methods** 1984 Oct;12(3):203–11

TRYPTAMINES

Effects of benzene and pyridine on the concentration of mouse striatal tryptamine and 5-hydroxytryptamine. Juorio AV, et al. **Biochem Pharmacol** 1985 Oct 15;34(20):3774–6

Analysis of the cardiovascular responses to central injection of tryptamine in rats. Krstić MK, et al. **Neuropharmacology** 1985 Jun;24(6):517–25

TRYPTOPHAN

The effects of dietary neurotransmitter precursors on human behavior. Lieberman HR, et al. **Am J Clin Nutr** 1985 Aug;42(2):366–70

Use of L-tryptophan in treating bulimia [letter] Krahn D, et al. **Am J Psychiatry** 1985 Sep;142(9):1130

Disturbances of tryptophan metabolism in mice acutely deprived of tryptophan. Jones ML, et al. **Ann Nutr Metab** 1985;29(4):209–15

A comparison of the cyclic nucleotide-dependent protein kinases using chemical cleavage at tryptophan and cysteine. Monken CE, et al. **Arch Biochem Biophys** 1985 Aug 1;240(2):888–903

Tryptophan imaging of membrane proteins. Kleinfeld AM. **Biochemistry** 1985 Apr 9;24(8):1874–82

Increased total activity in the rat after L-tryptophan plus the monoamine oxidase-A inhibitor amiflamine but not after L-tryptophan plus clorgyline. Archer T, et al. **Br J Pharmacol** 1985 Jul;85(3):581–90

The effect of tryptophan on biogenic amines in the hepatic portal circulation of the dog. Hussain MN, et al. **Can J Physiol Pharmacol** 1985 Jul;63(7):863–6

Fluorescence studies on tryptophan and sulfhydryl group changes of bovine lens crystallins in a photodynamic system. Andley UP, et al. **Curr Eye Res** 1985 Aug;4(8):831–42

Maturation of Escherichia coli tryptophan operon mRNA: evidence for 3' exonucleolytic processing after rho-dependent termination. Mott JE, et al. **EMBO J** 1985 Jul;4(7):1887–91

Tyrosine-to-tryptophan energy transfer and the structure of calf gamma-II crystallin. Borkman RF, et al. **Exp Eye Res** 1985 Jun; 40(6):819–26

A temperature dependent transition in the Pribnow box of the trp promoter. Lefevre JF, et al. **FEBS Lett** 1985 Oct 7;190(1):37–40

Successful nicotinamide treatment in an autosomal dominant behavioral and psychiatric disorder. Blom W, et al. **J Inherited Metab Dis** 1985; 8 Suppl 2:107–8

Effect of L-tryptophan on electroconvulsive therapy seizure time. Price WA, et al. **J Nerv Ment Dis** 1985 Oct;173(10):636–8

Could supplementary dietary tryptophan prevent sudden infant death syndrome? Maurizi CP. **Med Hypotheses** 1985 Jun;17(2):149–54

Pharmacological studies on the serotoninergic and nonserotonin-mediated stimulation of prolactin and corticosterone secretion by fenfluramine. Effects of pretreatment with fluoxetine, indalpine, PCPA, and L-tryptophan. Van de Kar LD, et al. **Neuroendocrinology** 1985 Oct; 41(4):283–8

Transport systems and enzymes involved in the metamorphosis of tryptophan into serotonin. Baumann P. **Pharmacopsychiatry** 1985 Mar; 18(2):188–92

The effect of pH on the aerobic and anaerobic photolysis of tryptophan and some tryptophan-containing dipeptides. Hibbard LB, et al. **Photochem Photobiol** 1985 Aug;42(2):99–106

Tryptophanyl fluorescence quenching of urocanase from Pseudomonas putida by acrylamide, cesium, iodide, and imidazolepropionate. O'Donnell PS, et al. **Photochem Photobiol** 1985 Aug;42(2):107–12

On gut membrane transport of tryptophan in the germfree mouse. Phillips AW. **Prog Clin Biol Res** 1985;181:81–5

[Chemical modification of tryptophan residues of leucyl tRNA synthetase by N-bromosuccinimide and 2-hydroxy-5-nitrobenzyl bromide] Korneliuk AI, et al. **Bioorg Khim** 1985 May;11(5):605–12 (Eng. Abstr.) **(Rus)**

[Tryptophan operon of methylotrophic facultative Pseudomonas sp. M bacteria. I. Isolation and characterization of auxotrophic Trp-mutants] Olekhnovich IN, et al. **Genetika** 1985 Jul;21(7):1099–104 (Eng. Abstr.) **(Rus)**

TRYPTOPHAN HYDROXYLASE

Regulatory properties of phenylalanine, tyrosine and tryptophan hydroxylases. Kaufman S. **Biochem Soc Trans** 1985 Apr;13(2):433–6

TYROSINE

The effects of dietary neurotransmitter precursors on human behavior. Lieberman HR, et al. **Am J Clin Nutr** 1985 Aug;42(2):366–70

Utilization of N-acetyl-L-tyrosine and glycyl-L-tyrosine during long-term parenteral nutrition in the growing rat. Neuhäuser M, et al. **Am J Clin Nutr** 1985 Oct;42(4):585–96

Effect of cocaine dependence on plasma phenylalanine and tyrosine levels and on urinary MHPG excretion. Tennant FS Jr. **Am J Psychiatry** 1985 Oct;142(10):1200–1

A simple and rapid method of quantitative analysis of phosphoamino acids by high-performance liquid chromatography. Morrice N, et al. **Anal Biochem** 1985 Jul;148(1):207–12

Protein-tyrosine kinases. Hunter T, et al. **Annu Rev Biochem** 1985; 54:897–930 (239 ref.)

Chorismate mutase-prephenate dehydrogenase from Escherichia coli: cooperative effects and inhibition by L-tyrosine. Christopherson RI.

Arch Biochem Biophys 1985 Aug 1;240(2):646–54

Chemical modification of liquefying alpha–amylase: role of tyrosine residues at its active center. Kochhar S, et al. **Arch Biochem Biophys** 1985 Aug 1;240(2):757–67

Purification of the catalytically active phosphorylated form of insulin receptor kinase by affinity chromatography with O–phosphotyrosyl–binding antibodies. Pang DT, et al. **Arch Biochem Biophys** 1985 Oct;242(1):176–86

A semisynthetic bovine pancreatic ribonuclease containing a unique nitrotyrosine residue. Sasaki DM, et al. **Arch Biochem Biophys** 1985 Aug 15;241(1):132–40

Introduction of the dansyl group into histidine and tyrosine residues in peptides and proteins. Buchta R, et al. **Biochem Biophys Res Commun** 1985 Jul 16;130(1):350–7

m–Fluorotyrosine substitution in beta–galactosidase; evidence for the existence of a catalytically active tyrosine. Ring M, et al. **Biochem Biophys Res Commun** 1985 Sep 16;131(2):675–80

Protein–bound glycogen is linked to tyrosine residues. Aon MA, et al. **Biochem J** 1985 Jul 1;229(1):269–72

1H n.m.r. studies of insulin. Assignment of resonances and properties of tyrosine residues. Bradbury JH, et al. **Biochem J** 1985 Aug 1; 229(3):731–7

Effect of metal ions on the kinetics of tyrosine oxidation catalysed by tyrosinase. Palumbo A, et al. **Biochem J** 1985 Jun 15;228(3):647–51

Observation of tyrosine–O–phosphate in Drosophila melanogaster larvae by 31P–NMR spectroscopy. Moore RR, et al. **Biochim Biophys Acta** 1985 Sep 30;846(3):394–7

The intrinsic tyrosine fluorescence of histone H1. Steady state and fluorescence decay studies reveal heterogeneous emission. Libertini LJ, et al. **Biophys J** 1985 Jun;47(6):765–72

Synthesis and characterization of six sequential polypeptides containing tyrosine, glutamic acid, alanine, and glycine by circular dichroism and difference spectroscopy. Zeiger AR, et al. **Biopolymers** 1985 Jul; 24(7):1215–32

Interaction of tyrosine residues with the chromophore in bacteriorhodopsin. Takeda K, et al. **Biosci Rep** 1985 Jul;5(7):615–23

Modification of the effects of repetitive restraint stress on brain biogenic amines by L–tyrosine. Quirce CM, et al. **Chung Kuo Yao Li Hsueh Pao** 1984 Dec;5(4):226–8

Vinculin and 36 kDa protein are not tyrosine–phosphorylated in Rous sarcoma virus infected cells which have been treated with interferon. Strube W, et al. **Eur J Cell Biol** 1985 Sep;38(2):226–33

Tyrosine–to–tryptophan energy transfer and the structure of calf gamma–II crystallin. Borkman RF, et al. **Exp Eye Res** 1985 Jun; 40(6):819–26

Structure and function of human C5a anaphylatoxin. Selective modification of tyrosine 23 alters biological activity but not antigenicity. Johnson RJ, et al. **J Biol Chem** 1985 Aug 25;260(18):10339–45

Affinity labeling of a tyrosine residue in the ATP binding site of the recA protein from Escherichia coli with 5'–p–fluorosulfonylbenzoyladenosine. Knight KL, et al. **J Biol Chem** 1985 Aug 25;260(18):10177–84

Tyrosine 264 in the recA protein from Escherichia coli is the site of modification by the photoaffinity label 8–azidoadenosine 5'–triphosphate. Knight KL, et al. **J Biol Chem** 1985 Aug 25; 260(18):10185–91

Biopterin, neopterin and tyrosine responses to combined oral phenylalanine and tetrahydrobiopterin loading tests in two normal children and in a girl with partial biopterin deficiency. Lykkelund C, et al. **J Inherited Metab Dis** 1985;8 Suppl 2:95–6

Deuterium isotope effect in the transamination of p–tyrosine by rat liver tyrosine transaminase. Yu PH, et al. **Life Sci** 1985 Oct 7; 37(14):1287–91

Comparison of the ability of thyroxine and triiodothyronine to suppress TRH–induced TSH secretion by perfused rat anterior pituitary fragments. Ikeda H, et al. **Neuroendocrinology** 1985 Jul;41(1):79–82

Dietary D–tyrosine as an antimetabolite in mice. **Nutr Rev** 1985 May; 43(5):156–8 (14 ref.)

(Glu62, Ala30, Tyr8)n serves as high–affinity substrate for tyrosylprotein sulfotransferase: a Golgi enzyme. Lee RW, et al. **Proc Natl Acad Sci USA** 1985 Sep;82(18):6143–7

Phosphotyrosine–containing proteins are concentrated in focal adhesions and intercellular junctions in normal cells. Maher PA, et al. **Proc Natl Acad Sci USA** 1985 Oct;82(19):6576–80

[Synthesis of tyrosine and 3,4–dihydroxyphenylalanine by Citrobacter freundii bacteria from lactic acid] Kupletskaia MB. **Prikl Biokhim Mikrobiol** 1985 May–Jun;21(3):342–8 (Eng. Abstr.) **(Rus)**

TYROSINE AMINOTRANSFERASE

A new glucocorticoid receptor species: relation to induction of tryptophan dioxygenase by glucocorticoids. Hirota T, et al. **Endocrinology** 1985 Nov;117(5):1788–95

Effect of selective parasympathetic denervation on the daily rhythm of tyrosine transaminase in the rat liver. Magni F, et al. **J Auton Nerv Syst** 1985 Jul;13(3):245–54

Complete complementary DNA of rat tyrosine aminotransferase messenger RNA. Deduction of the primary structure of the enzyme. Grange T, et al. **J Mol Biol** 1985 Jul 20;184(2):347–50

Isolation, characterization and chromosomal mapping of the mouse tyrosine aminotransferase gene. Müller G, et al. **J Mol Biol** 1985 Aug 5;184(3):367–73

Deuterium isotope effect in the transamination of p–tyrosine by rat liver tyrosine transaminase. Yu PH, et al. **Life Sci** 1985 Oct 7; 37(14):1287–91

[Inhibitory effect of progesterone on the stimulation of tryptophan pyrrolase and tyrosine aminotransferase by endogenous corticosteroids in the liver of female rats] Németh S, et al. **Bratisl Lek Listy** 1985 Jul;84(1):3–10 (Eng. Abstr.) **(Slo)**

TYROSINE HYDROXYLASE

Activation of tyrosine hydroxylase in the central nervous system by anaerobiosis. Pastuszko A, et al. **Biochem Pharmacol** 1985 Aug 15; 34(16):2975–82

Regulatory properties of phenylalanine, tyrosine and tryptophan hydroxylases. Kaufman S. **Biochem Soc Trans** 1985 Apr;13(2):433–6

Homology between phenylalanine and tyrosine hydroxylases reveals common structural and functional domains. Ledley FD, et al. **Biochemistry** 1985 Jul 2;24(14):3389–94

Trans–synaptic increase in RNA coding for tyrosine hydroxylase in a rat sympathetic ganglion. Black IB, et al. **Brain Res** 1985 Jul 22; 339(1):151–3

Evidence for specific immunolysis of nerve terminals using antisera against choline acetyltransferase, glutamate decarboxylase and tyrosine hydroxylase. Docherty M, et al. **Brain Res** 1985 Jul 22; 339(1):105–13

Changes in tyrosine hydroxylase, glutamic acid decarboxylase and choline acetyltransferase after local microinoculation of scrapie agent into the nigrostriatal system of the golden hamster. Durand–Gorde JM, et al. **Brain Res** 1985 Aug 26;341(2):243–51

Long–term regulation of tyrosine hydroxylase activity in the superior cervical ganglion in organ culture: effects of nerve stimulation and dexamethasone. Ip NY, et al. **Brain Res** 1985 Jul 8;338(1):61–70

Coexistence of immunoreactivities for glutamate decarboxylase and tyrosine hydroxylase in some neurons in the periglomerular region of the rat main olfactory bulb: possible coexistence of gamma–aminobutyric acid (GABA) and dopamine. Kosaka T, et al. **Brain Res** 1985 Sep 16; 343(1):166–71

Tyrosine hydroxylase immunohistochemistry fails to demonstrate dopaminergic interplexiform cells in the turtle retina. Nguyen–Legros J, et al. **Brain Res** 1985 Jul 29;339(2):323–8

SCH 23390, a selective D1 dopamine receptor blocker, enhances the firing rate of nigral dopaminergic neurons but fails to activate striatal tyrosine hydroxylase. Onali P, et al. **Brain Res** 1985 Aug 5;340(1):1–7

Identification of dopamine–containing cell bodies in the dorsal and median raphe nuclei of the rat brain using tyrosine hydroxylase immunochemistry. Trulson ME, et al. **Brain Res Bull** 1985 Aug; 15(2):229–34

Direct effects of adrenocorticotropic hormone on bovine adrenomedullary cells: adenosine 3',5'–monophosphate–dependent phosphorylation of tyrosine hydroxylase. Michener ML, et al. **Endocrinology** 1985 Aug; 117(2):730–7

Presynaptic dopamine and serotonin receptors modulating tyrosine hydroxylase activity in synaptosomes of the nucleus accumbens of rats. Hetey L, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):1–10

Genes for neurotransmitter synthesis, storage, and uptake. Joh TH, et al. **Fed Proc** 1985 Sep;44(12):2773–9

Nerve growth factor and other agents mediate phosphorylation and activation of tyrosine hydroxylase. A convergence of multiple kinase activities. McTigue M, et al. **J Biol Chem** 1985 Jul 25; 260(15):9047–56

The fine structural organization of tyrosine hydroxylase immunoreactive neurons in rat arcuate nucleus. Piotte M, et al. **J Comp Neurol** 1985 Sep 1;239(1):44–53

Study of dopamine turnover by monitoring the decline of dopamine metabolites in rat CSF after alpha–methyl–p–tyrosine. Mignot E, et al. **J Neurochem** 1985 Nov;45(5):1527–33

Elevation of RNA coding for tyrosine hydroxylase in rat adrenal gland by reserpine treatment and exposure to cold. Tank AW, et al. **J Neurochem** 1985 Oct;45(4):1030–3

Genetic effects and sexual dimorphism in tyrosine hydroxylase activity in two mouse strains and their reciprocal F1 hybrids. Vadász C, et al. **J Neurogenet** 1985 Jun;2(3):219–30

Regulation of the concentration of adenosine 3',5'–cyclic monophosphate and the activity of tyrosine hydroxylase in the rat superior cervical ganglion by three neuropeptides of the secretin family. Ip NY, et al. **J Neurosci** 1985 Jul;5(7):1947–54

Coexistence of growth hormone releasing factor–like and tyrosine hydroxylase–like immunoreactivities in neurons of the rat arcuate nucleus. Okamura H, et al. **Neuroendocrinology** 1985 Aug; 41(2):177–9

Simultaneous ultrastructural localization of cholecystokinin– and tyrosine hydroxylase-like immunoreactivity in nerve fibers of the rat nucleus accumbens. Loopuijt LD, et al. **Neurosci Lett** 1985 May 23; 56(3):329–34

Morphology and distribution of tyrosine hydroxylase-like immunoreactive neurons in the cat retina. Oyster CW, et al. **Proc Natl Acad Sci USA** 1985 Sep;82(18):6335–9

VANILMANDELIC ACID

The in vivo effects of prostaglandin F2 alpha and prostaglandin E2 on rat urinary excretion of vanillylmandelic acid. Yamada K, et al. **Res Commun Chem Pathol Pharmacol** 1985 Jul;49(1):137–40

Analysis of vanillylmandelic and homovanillic acids in urine using solid phase sample preparation and high pressure liquid chromatography with electrochemical detection. Bremmelgaard A. **Scand J Clin Lab Invest** 1985 Sep;45(5):387–91

VASOPRESSINS

Effect of norepinephrine and vasopressin on renal kallikrein excretion in rats. Martinez Seeber A, et al. **Arch Int Physiol Biochim** 1985 Jun; 93(2):83–8

Salt-dependent structural changes of neurohormones: lithium ions induce conformational rearrangements of ocytocin to a vasopressin-like structure. Rholam M, et al. **Biochemistry** 1985 Jun 18;24(13):3345–9

Coexistence of vasopressin, neurophysin and noradrenaline immunoreactivity in medium-sized cells of the locus coeruleus and subcoeruleus in the rat. Caffé AR, et al. **Brain Res** 1985 Jul 8; 338(1):160–4

Renal nerve stimulation causes alpha 1-adrenoceptor-mediated sodium retention but not alpha 2-adrenoceptor antagonism of vasopressin. Smyth DD, et al. **Circ Res** 1985 Aug;57(2):304–11

Augmentation of the response to CRF in man: relative contributions of endogenous angiotensin and vasopressin. Milsom SR, et al. **Clin Endocrinol (Oxf)** 1985 May;22(5):623–9

Effect of substances influencing brain serotonergic transmission on plasma vasopressin levels in the rat. Iovino M, et al. **Eur J Pharmacol** 1985 Jul 11;113(1):99–103

Inhibition of the hydro-osmotic response to vasopressin and hypertonicity by phenothiazines and W7, calmodulin antagonists. Yorio T, et al. **Gen Pharmacol** 1985;16(4):347–53

The role of extracellular Ca2+ in the response of the hepatocyte to Ca2+-dependent hormones. Joseph SK, et al. **J Biol Chem** 1985 Oct 15;260(23):12508–15

Catecholamine and vasopressin stimulation of gluconeogenesis from dihydroxyacetone in the presence of atractyloside. Warnette-Hammond ME, et al. **J Biol Chem** 1985 Oct 15;260(23):12647–52

Inhibition by prostaglandin E2 of the release of vasopressin and beta-endorphin from rat pituitary neurointermediate lobe or medial basal hypothalamus in vitro. Knepel W, et al. **J Endocrinol** 1985 Aug; 106(2):189–95

Diuresis and suppression of vasopressin by kappa opioids: comparison with mu and delta opioids and clonidine. Leander JD, et al. **J Pharmacol Exp Ther** 1985 Aug;234(2):463–9

Co-localization of corticotropin-releasing factor and vasopressin in median eminence neurosecretory vesicles. Whitnall MH, et al. **Nature** 1985 Sep 19–25;317(6034):248–50

VASOTOCIN

Plasma concentrations of arginine vasotocin, prolactin, aldosterone and corticosterone in relation to oviposition and dietary NaCl in the domestic fowl. Rice GE, et al. **Comp Biochem Physiol [A]** 1985; 81(4):769–77

Pineal ultrastructure and indole profiles spanning the summer rise in arginine vasotocin immunoactivity. McNulty JA, et al. **Endocrinology** 1985 Sep;117(3):1035–42

An immunohistochemical study of seasonal changes in luteinizing hormone-releasing hormone and vasotocin in the forebrain and the neurohypophysis of the toad, Bufo japonicus. Jokura Y, et al. **Gen Comp Endocrinol** 1985 Aug;59(2):238–45

VISUAL PERCEPTION

Role of intralaminar thalamus in gaze mechanisms: evidence from electrical stimulation and fiber-sparing lesions in cat. Merker B, et al. **Exp Brain Res** 1985;59(2):388–94

Early visual information processing in depressive patients treated with ORG 2766 (an ACTH 4-9 analogue). d'Elia G, et al. **Neuropsychobiology** 1985;13(1-2):63–8

WAKEFULNESS

Sleep and wake after benzodiazepine hypnotics: a 20-hour EEG comparison of lormetazepam and flunitrazepam. Timsit-Berthier M, et al. **Curr Med Res Opin** 1985;9(8):552–9

ZIMELIDINE

Synthesis and spectroscopic characterization of pyridyl N-oxidized zimeldine metabolites. Högberg T, et al. **Acta Pharm Suec** 1985; 22(3):123–30

Double-blind comparison between a serotonin and a noradrenaline reuptake blocker in the treatment of depressed outpatients. Clinical aspects. Nyström C, et al. **Acta Psychiatr Scand** 1985 Jul;72(1):6–15

Profiles of antidepressant activity with the Montgomery-Asberg Depression Rating Scale. Montgomery SA, et al. **Acta Psychiatr Scand [Suppl]** 1985;320:38–42

The effects of zimeldine on voluntary ethanol consumption: studies on the mechanism of action. Gill K, et al. **Alcohol** 1985 Mar–Apr; 2(2):343–7

Influence of renal failure on the kinetics of zimeldine and norzimelidine. Ferry N, et al. **Eur J Clin Pharmacol** 1985;28(4):453–6

*U.S. GOVERNMENT PRINTING OFFICE: 1986-491-327:21002

The *Psychopharmacology Bulletin* is available on subscription from the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402. Subscription price $19.00 per year for the United States. All other countries add $4.75 for postage. This price was in effect at time of printing. Prices are subject to change. Please make check or money order payable to the Superintendent of Documents. An annual subscription for four quarterly issues begins with the next issue following receipt of the order. Single copies and back issues may also be ordered from the Superintendent of Documents. The expiration date is printed on the top line of the address label. Change of address and complaints about non-receipt of issues should be sent to the Superintendent of Documents and should include the old address, preferably a mailing label, as well as the new address.

The *Psychopharmacology Bulletin* is prepared by the Division of Clinical Research of the National Institute of Mental Health. Its purpose is to facilitate the dissemination and exchange of information among the national and international scientific community. This emphasis is on rapid, informal reporting of work which has not appeared in the more formal literature. In accordance with new policy set forth by our Associate Editors, we are no longer accepting unsolicited papers for publication in the *Bulletin*.

All material published in the *Psychopharmacology Bulletin* is in the public domain unless otherwise noted. Publication in the *Bulletin* therefore does not preclude publication elsewhere.

Table of Contents

NEWARK PUBLIC LIBRARY
NOV 5 1986
U. S. GOVT.
DEPOSITORY 326

24th Annual Meeting of the ACNP–1985—Abridged Proceedings—

Strategies for Advance in Maintenance Therapies

553 Maintenance Phenelzine Treatment of Major Depression: An Interim Report—*Donald S. Robinson, Allen Kayser, Binni Bennett, Elizabeth Devereaux, Sidney C. Lerfald, Doris Albright, Desmonde Laux, and John Corcella*

558 Psychotherapeutic Approaches to Treatment of Recurrent Unipolar Depression: Work in Progress—*Ellen Frank and David J. Kupfer*

Peripheral Hormones: A Window on the Central MA?—

565 The Pitfalls of Serotonin Precursors as Challengers in Hormonal Probes of Central Serotonin Activity—*Herman M. van Praag, Carmen Lemus, and Rene Kahn*

571 The Desipramine Cortisol Test—A Selective Noradrenergic Challenge (Relationship to Other Cortisol Tests in Depressives and Normals)—*Gregory M. Asnis, Carmen Z. Lemus, and Uriel Halbreich*

Etiological Theories of Depression: Experimental Paradigms in Animals—

579 A Developmental Perspective on Recurrent Mood Disorders: A Review of Studies in Man—*Hagop S. Akiskal*

587 Developmental Theories of Depression in Nonhuman Primates—*Gary W. Kraemer*

Biochemical and Functional Studies of D-1 Dopamine Receptors—

593 Multiple Forms of the D_1 Dopamine Receptor: Its Linkage to Adenylate Cyclase and Psychopharmacological Effects—*Richard B. Mailman, David W. Schulz, Clinton D. Kilts, Mark H. Lewis, Hans Rollema, and Steven Wyrick*

599 Structural Analogs of SCH 23390 as Discriminators of Dopamine Receptor Subtypes: Behavioral Interactions Between D-1 and D-2 Agonists and Antagonists—*Kathy M. O'Boyle, Anthony G. Molloy, Marcellina Mashurano, and John L. Waddington*

605 Biochemical and Behavioral Studies of D_1 Dopamine Receptors Utilizing SCH23390—*Ellen J. Hess and Ian Creese*

Mixed Mania: Diagnosis and Treatment—

613 Sources of Lithium Resistance in Mixed Mania—*Jonathan M. Himmelhoch and Marc E. Garfinkel*

Expressed Emotion of Relatives, Maintenance Drug Treatment, and Relapse in Schizophrenia and Mania—

621 Expressed Emotion, Maintenance Pharmacotherapy, and Schizophrenic Relapse Among Mexican-Americans—*Janis H. Jenkins, Marvin Karno, Aurora de la Selva, Felipe Santana, Cynthia Telles, Steven Lopez, and Jim Mintz*

628 Expressed Emotion, Affective Style, Lithium Compliance, and Relapse in Recent Onset Mania—*David J. Miklowitz, Michael J. Goldstein, Keith H. Nuechterlein, Karen S. Snyder, and Jeri A. Doane*

633 Expressed Emotion, Fixed-Dose Fluphenazine Decanoate Maintenance, and Relapse in Recent-Onset Schizophrenia—*Keith H. Nuechterlein, Karen S. Snyder, Michael E. Dawson, Sandra*

Rappe, Michael Gitlin, and David Fogelson

The Benzodiazepine/GABA Receptor: From Molecular Structure to Function in Man—

641 Molecular Aspects of Benzodiazepine Receptor Function—*Paul Sweetnam, Peter Gallombardo, and John Tallman*

Neurochemical Correlates of Suicide—

647 Postmortem Serotonergic and Adrenergic Receptor Binding to Frontal Cortex: Correlations With Suicide—*J. John Mann, P. Anne McBride, and Michael Stanley*

650 Suicide and Adrenocortical Function—*James H. Kocsis, Sara Kennedy, Richard P. Brown, J. John Mann, and Barbara Mason*

656 Suicidal Potential in Depression: Focus on CSF Monoamine and Purine Metabolites—*Hans Ågren and Frank Niklasson*

661 Monoamines, Glucose Metabolism, Suicidal and Aggressive Behaviors—*Alec Roy, Matti Virkkunen, Sally Guthrie, Russell Poland, and Markku Linnoila*

666 Genetic Factors in Suicide—*Alec Roy*

669 (Auto)Aggression and CSF 5-HIAA in Depression and Schizophrenia—*Herman M. van Praag*

Acquired Immunodeficiency Syndrome (AIDS): Neuropsychologic and Psychoimmunologic Aspects—

675 Introduction—*T. Peter Bridge and Donald I. Macdonald*

678 Psychosocial Aspect of AIDS Risk—*David G. Ostrow, Jill Joseph, Andrew Monjan, Ronald Kessler, Carol Emmons, John Phair, Robin Fox, Lawrence Kingsley, Janice Dudley, Joan S. Chmiel, and Mark Van Raden*

684 Neuropsychiatric Aspects of AIDS—*Russell T. Joffe, David R. Rubinow, Kathleen Squillace, Clifford H. Lane, Connie C. Duncan, and Anthony S. Fauci*

689 Localization of the T4 Antigen/AIDS Virus Receptor in Monkey and Rat Brain: Prominence in Cortical Regions—*Joanna M. Hill, William L. Farrar, and Candace B. Pert*

695 Methionine Enkephalin: Enhancement of T-Cells in Patients With Kaposi's Sarcoma (AIDS)—*N.P. Plotnikoff, J. Wybran, N.F. Nimeh, and G.C. Miller*

Molecular Biology: Relevance to Neuropsychopharmacology and Psychiatry—

699 Introduction—*Samuel H. Barondes*

701 Identifying Neuropeptides by Gene Cloning—*Floyd E. Bloom*

708 Use of Gene Transfer Techniques to Study Neuropeptide Gene Regulation—*Edward Herbert, Audrey F. Seasholtz, and Michael Comb*

Neuropsychopharmacology of Alcohol and Drug Abuse—

717 Interactions of Alcohol and Drugs of Abuse—*Monique C. Braude*

Neuropharmacological Approaches to the Obsessive-Compulsive Syndrome—

723 Epidemiologic and Clinical Findings of Significance to the Design of Neuropharmacologic Studies of Obsessive-Compulsive Disorder—*Steven A. Rasmussen and Ming T. Tsuang*

730 A Possible Genetic Relationship Exists Between Tourette's Syndrome and Obsessive-Compulsive Disorder—*David L. Pauls, James F. Leckman, Kenneth E. Towbin, Gwendolyn Zahner, and Donald J. Cohen*

Problems and Promises of Post-Mortem Brain Tissue Analysis—

735 Role of the Serotonergic System in the Postmortem Analysis of Suicide—*Michael Stanley, J. John Mann, and Lee S. Cohen*

741 Aminergic Receptor Binding Correlates of Suicide: Methodological Issues—*J. John Mann, P. Anne McBride, and Michael Stanley*

Appetite and Satiety Regulation: Pharmacological Strategies—

745 Neuropeptides as Stimulators of Feeding—*John E. Morley, James E. Mitchell, and Allen S. Levine*

Psychotoxic Manifestations in Amphetamine Abuse—

751 Acute Exacerbation of Methamphetamine Psychosis and Lasting Dopaminergic Supersensitivity—A Clinical Survey—*Mitsumoto Sato*

757 Reverse Tolerance to the Ambulation-Increasing Effect of Methamphetamine in Mice as an Animal Model of Amphetamine-Psychosis—*Sakutaro Tadokoro and Hisashi Kuribara*

763 Psychotic Manifestations in Amphetamine Abuse—Experimental Study on the Mechanism of Psychotic Recurrence—*Kiyoshi Ando, Naoyuki Hironaka, and Tomoji Yanagita*

768 Visual Perception Process in Amphetamine Psychosis and Schizophrenia—*Takuya Kojima, Eisuke Matsushima, Hisayuki Iwama, Harunobu Ando, Hirobumi Moriya, Katsumi Ando, Ryo Takahashi, and Yasuo Shimazono*

Membrane Lipids: From Signal Transduction to Neuropsychiatric Disease—

775 Changes in Receptor Stimulated Phosphoinositide Hydrolysis in Brain During Ethanol Administration, Aging, and Other Pathological Conditions—*Fulton T. Crews, Rueben A. Gonzales, Reinhard Palovcik, M. Ian Phillips, Cynthia Theiss, and Mohan Raizada*

781 "Autocannibalism" of Membrane Choline-Phospholipids: Physiology and Pathology—*Jan K. Blusztajn, Pamela G. Holbrook, Michael Lakher, Mordechai Liscovitch, Jean-Claude Maire, Charlotte Mauron, U. Ingrid Richardson, Mariateresa Tacconi, and Richard J. Wurtman*

Panic Disorder: Clinical Characteristics, Epidemiology, and Treatment—

787 The Relationship Between Panic Disorder and Agoraphobia: An Epidemiologic Perspective—*Myrna M. Weissman, Philip J. Leaf, Dan G. Blazer, Jeffrey H. Boyd, and Louis Florio*

792 Recent Developments in the Understanding and Pharmacotherapy of Panic Attacks—*Michael R. Liebowitz, Abby J. Fyer, Jack Gorman, and Donald F. Klein*

797 Possible Respiratory Abnormalities in Panic Disorder—*Jack M. Gorman, Michael R. Liebowitz, Abby J. Fyer, Minna R. Fyer, and Donald F. Klein*

802 Behavioral Conception and Treatment of Panic—*David H. Barlow*

Etiology and Treatment: Basic and Clinical Neuroscience Investigations—

807 Nonbenzodiazepine Anxiolytics: Insights Into Possible Mechanisms of Action—*Cam P. VanderMaelen, Duncan P. Taylor, Greta Gehlbach, and Michael S. Eison*

Serotonin Receptor Subtypes: Biochemical, Physiological, Behavioral, and Clinical Implications—

813 Analysis of 5-HT$_1$ Binding Site Subtypes and Potential Functional Correlates—*Stephen J. Peroutka, Richard E. Heuring, Michael D. Mauk, and Jeffery D. Kocsis*

818 Labeling of the 5-HT$_{1A}$ Receptor Subtype—*Jean C. Shih, Kenneth B. Asarch, and Richard Ransom*

825 Substituted Phenylpiperazines as Serotonin Agonists: Structural Determinants of Potency and Interaction With Receptor Subtypes—*Ray W. Fuller*

829 Effector Systems Coupled to Serotonin Receptors in Brain: Serotonin Stimulated Phosphoinositide Hydrolysis—*Elaine Sanders-Bush and P. Jeffrey Conn*

837 Serotonin Receptor Subtype Agonists: Differential Effects on Sensorimotor Reactivity Measured With Acoustic Startle—*Michael Davis, James V. Cassella, William H. Wren, and John H. Kehne*

Influences of Pharmacologic and Psychosocial Factors on the Course of Schizophrenia—

845 Prediction of Relapse in Schizophrenia—*Jeffrey A. Lieberman, John M. Kane, Stavros Sarantakos, Dominick Gadaletta, Margaret Woerner, Jose Alvir, and Jorge Ramos-Lorenzi*

854 Interpersonal and Pharmacologic Treatment in Schizophrenia: A Comparative Study of New Approaches—*William T. Carpenter, Jr., Douglas W. Heinrichs, and Thomas E. Hanlon*

860 Medication, Family Psychoeducation, and Social Skills Training: First Year Relapse Results of a Controlled Study—*Gerard E. Hogarty and Carol M. Anderson*

Nicotine as a Psychoactive Drug: Anxiety and Pain Reduction, Arousal, and Appetite Regulation—

863 Introduction—*Ovide F. Pomerleau*

865 Nicotine as a Psychoactive Drug: Anxiety and Pain Reduction—*Ovide F. Pomerleau*

870 Nicotine: A Unique Psychoactive Drug—Arousal With Skeletal Muscle Relaxation—*Edward F. Domino*

875 Nicotine as a Psychoactive Drug: Appetite Regulation—*Neil E. Grunberg*

882 Nicotine as a Psychoactive Drug—Panel Summary—*Murray E. Jarvik*

Basic and Clinical Aspects of Prefrontal Cortex Physiology in Neuropsychiatry—

885 Electrophysiological Evidence Implicating Frontal Lobe Dysfunction in Schizophrenia—*John M. Morihisa*

Neuroleptic-Induced Psychological Supersensitivity Syndromes: Are These Syndromes Myth or Reality?—

891 Supersensitivity Psychosis and Tardive Dyskinesia: A Survey in Schizophrenic Outpatients—*Guy Chouinard, Lawrence Annable, and Andree Ross-Chouinard*

897 Associations Among Plasma Prolactin Levels, Tardive Dyskinesia, and Paranoia in Treated Schizophrenics: Relevance to Supersensitivity Psychosis—*John G. Csernansky, Sophia Vinogradov, Elisabeth Prosser, Jonathan Kaplan, Philip A. Berger, and Leo E. Hollister*

900 Basic and Clinical Studies of Neuroleptic-Induced Supersensitivity Psychosis and Dyskinesia—*Bruce I. Diamond and Richard L. Borison*

Recent Advances in HPA Physiology and Pathophysiology (II)—

907 Corticotropin-Releasing Hormone—A New Tool to Investigate Hypothalamic-Pituitary-Adrenocortical Physiology in Psychiatric Patients—*Florian Holsboer*

913 Multiendocrine Assessment in the Dexamethasone Suppression Test—*S. Craig Risch, David S. Janowsky, Lewis L. Judd, Christian Gillin, Mariam Mott, Jeffrey L. Rausch, and Leighton Y. Huey*

Recent Advances in Biomedical Research in Schizophrenia—

917 Introduction—*Robert O. Friedel*

918 The Genetics of Schizophrenia: A Current Perspective—*Kenneth S. Kendler*

923 The Dopamine Hypothesis: Variations on a Theme (II)—*Richard Jed Wyatt*

928 The Combined Use of Neuroleptics and ECT in Drug Resistant Schizophrenic Patients—*Robert O. Friedel*

Psychotropic Drug Receptors and Brain Function: Molecular Bases to Clinical Implications (CINP/ACNP)—

931 Lack of Serotonergic Modulation on ^{3}H-Imipramine Binding Sites in Basal Conditions and During Prolonged Treatment With Desmethylimipramine—*Nicoletta Brunello, Alessandra Cecilia Rovescalli, Marco Riva, and Giorgio Racagni*

Drug Washout Effects on Clinical Studies in Depression and Schizophrenia—

937 Effects of Drug Washout on CSF Monoamine and Psychoendocrine Variables—*Hans Ågren and William Z. Potter*

Brain Norepinephrine and Stress: A Vertical Synthesis—

943 Behavioral Depression Following Clonidine Withdrawal: A New Animal Model of Long-Lasting Depression?—*Laura J. Hoffman and Jay M. Weiss*

Mechanisms of Action of Indole and Phenylalkylamine Hallucinogens—

951 Introduction—*Richard H. Rech*

953 Structure-Activity Relationships and Mechanism of Action of Hallucinogenic Agents Based on Drug Discrimination and Radioligand Binding Studies—*Richard A. Glennon, Milt Titeler, and Richard Young*

959 The Use of Drug Discrimination Procedures to Characterize Hallucinogenic Drug Actions—*James B. Appel and Kathryn A. Cunningham*

968 Disruption of Operant Behavior by Hallucinogenic Drugs—*Richard H. Rech and David J. Mokler*

973 Comparison of Phencyclidine and Related Substances With Various Indole, Phenethylamine, and Other Psychotomimetics—*Edward F. Domino*

977 Clinical Aspects of Use of Phenylalkylamine and Indolealkylamine Hallucinogens—*Leo E. Hollister*

The "Pros" and "Cons" of Anticholinergic Prophylaxis—

981 Anticholinergic Prophylaxis in Young Adults Treated With Neuroleptic Drugs—*C. Raymond Lake, Daniel E. Casey, Joseph P. McEvoy, Samuel G. Siris, William F. Boyer, and George Simpson*

Poster Sessions—Editors' Choice

24th Annual Meeting of the ACNP-1985— Abridged Proceedings—

The 24th Annual Meeting of the American College of Neuropsychopharmacology (ACNP) was held in Maui, Hawaii, in December 1985.

This meeting annually brings together investigators actively involved in psychopharmacologic research. The papers presented at the sessions are indicative of the state of the art in psychopharmacology in this country and abroad.

For those who did not attend the conference, we publish summaries of the presentations. In some cases, not all of the papers in a session were received in time for inclusion. Publication of these summaries in the *Bulletin* does not prejudice later publication of the full papers elsewhere.

Because of the size of the ACNP meeting, we are no longer able to publish all Poster Session papers. Instead, an "Editors' Choice" section of the proceedings includes a limited number of Posters judged especially noteworthy by the Editors.

Strategies for Advance in Maintenance Therapies

Maintenance Phenelzine Treatment of Major Depression: An Interim Report[1]

Donald S. Robinson, M.D.,[2,3] Allen Kayser, M.D.,[3] Binni Bennett, M.S.W.,[3] Elizabeth Devereaux, A.C.S.W.,[3] Sidney C. Lerfald, M.D.,[3] Doris Albright, R.N.,[3] Desmonde Laux, Ph.D.,[3] and John Corcella, M.D.[3,4]

Introduction

The efficacy, safety, and optimal duration of long-term antidepressant drug treatment of depression are unresolved issues currently being investigated by several groups. There are no existing controlled studies of monoamine oxidase inhibitors (MAOI) in long-term maintenance therapy. In a 5-year study in progress at Marshall University, patients with a Research Diagnostic Criteria (RDC) diagnosis of major depressive disorder (Spitzer, Endicott, & Robins, 1978), and at least one prior lifetime episode of depression, are eligible for entry into a double-blind 2-year phenelzine maintenance treatment study. After initial clinical improvement and remission of depressive symptoms for a minimum of 16 weeks, patients are randomly assigned to placebo or one of two doses of phenelzine.

Method

After several months of regularly scheduled planning sessions, an interdisciplinary research group at Marshall University developed and submitted a study protocol to the National Institute of Mental Health in response to a request for applications to study long-term somatic treatment of affective disorders. The first patients entered into the study protocol in January 1983.

Specific aims of this study of maintenance treatment were to: (1) assess the efficacy and side effects of long-term phenelzine treatment, (2) establish an effective therapeutic maintenance dose range for phenelzine, (3) assess platelet MAO inhibition levels during long-term phenelzine treatment, and (4) study the pharmacokinetics of phenelzine during short- and long-term treatment. This interim report presents the preliminary findings related to the first specific aim of this study of maintenance phenelzine treatment for major depression.

The patient sample was drawn from the outpatient clinics at Marshall University Department of Psychiatry and Prestera Community Mental Health Center in Huntington, West Virginia. The patients were interviewed and screened by the research staff in the Mood Disorders Clinic at Marshall University School of Medicine. After written informed consent was obtained, patients who met entry criteria were assigned to one of four physician-therapist pairs who followed the patients throughout the course of treatment.

Criteria for entry into the study were: (1) major depressive disorder by Research Diagnostic Criteria (Spitzer, Endicott, & Robins, 1978), (2) Hamilton depression (Ham-D) score ≥ 18, (3) Global Assessment Scale (GAS) score ≤ 60, (4) Raskin Depression Scale score ≥ 7, and (5) at least one prior lifetime episode of either RDC major or minor depression.

Exclusion criteria included: (1) a remission period of less than 20 weeks between the index episode and the most recent prior episode, (2) presence of a major nonaffective psychiatric disorder, (3) history of mania or hypomania, (4) history of alcohol or substance abuse during the year prior to entry, and (5) pregnancy, epilepsy, or any medical illness which contraindicated the use of phenelzine.

The rationale for requiring a prior lifetime episode of depression as an entry criterion was based on data from a previous 6-week antidepressant drug trial comparing amitriptyline and phenelzine for the treatment of depressed outpatients (Ravaris et al., 1980; Robinson et al., 1985). A retrospective study of the West Virginia outpatient sample indicated that these patients were at considerable risk for recurrence of depression within a 2-year period following remission of the acute episode. Sixty of 66 patients who participated in this double-blind comparison drug study responded to a post-study inquiry (85% follow-up rate). Forty of these 60 patients (67%) suffered a recurrence of depression in the ensuing 1–3 years after they completed a successful course (usually a minimum of 6 months) of antidepressant drug treatment for their index episode. Even though the recurrence rate for patients with no prior episodes was nearly as high as the rate for patients with a history of depression, the inclusion criterion of one or more prior episodes was established to achieve greater sample homogeneity and to address the ethical issue of committing patients to 2 years of drug treatment.

Patients were evaluated initially by a screening interview and re-evaluated after a drug-free interval of at least 1 week. Then, if patients qualified for entry into the study, baseline psychometric and laboratory evaluations were performed. Patients underwent physical examination, clinical laboratory tests, and an ECG. In addition, blood samples were collected for platelet MAO assay and plasma phenelzine concentration. Clinical evaluations included the Schedule for Affective Disorders (SADS) interview (Endicott & Spitzer, 1978), Hamilton Depression Scale, Raskin Severity of Depression Scale, and the Global Assessment Scale (Endicott et al., 1976). Patients were initially seen by both members of the physician-therapist treatment team, and the clinical assessments and ratings were jointly reviewed. Patients were then started on non-blind treatment with phenelzine (target dosage of 1 mg/kg/day). In the first study year, phenelzine treatment was initiated on an individualized dosage schedule during the first week, followed by a gradual increase to an optimal therapeutic dose based upon clinical response and/or tolerance of side effects. For the past two years, phenelzine treatment was initiated with the target dosage of approximately 1 mg/kg/day in divided doses. Most of the patients were seen weekly (during this acute treatment phase) until they achieved satisfactory therapeutic response (defined as Ham-D <10, Raskin ≤ 5, GAS ≥ 70). Patients were required to maintain this level of response, without interruption for a minimum period of 16 weeks (continuation treatment phase) before they were entered into one of three double-blind, randomly assigned drug treatment groups.

Upon satisfactory completion of the continuation treatment phase, patients were entered into the maintenance treatment phase, a 24-month double-blind comparison of three different maintenance dose regimens, phenelzine 60 mg/day, phenelzine 45 mg/day, or placebo, administered in two capsules twice a day. Patients who were randomized to the placebo treatment group had their phenelzine dose tapered weekly by 15 mg/day in prepackaged capsules during the first 3 weeks of the double-blind maintenance treatment phase. Patients were seen at least every 4 weeks during the 2-year maintenance phase, or more frequently if clinically indicated.

Psychotherapeutic interventions consisted mainly of patient and family education about depressive illness and importance of medication and dietary compliance. Recognizing that recurrent depression occurs within a social and interpersonal context which interacts with biological vulnerabilities and personality traits (Weissman et al., 1981), patient-initiated topics related to psychosocial stress and life crises occurring during the study were addressed using a supportive, "here and now," problem-solving psychotherapeutic approach. Possible side effects were elicited during all three phases of the study, and careful monitoring for early re-emergence of symptoms was assessed on a routine basis, especially during the maintenance treatment phase of the study. Re-emergence of symptoms was defined as Ham-D ≥ 18, Raskin ≥ 7, and GAS ≤ 60 in the presence of depressive symptoms meeting RDC criteria for major depressive episode of 2-weeks duration.

Results

From January 1983 to November 1985, 231 patients were evaluated for study eligibility in the Mood Disorders Clinic. Of these, 79 patients were eligible for admission and willing to participate in the study. Sixty-five of the 79 patients (82%) showed a favorable therapeutic response to phenelzine during the acute treatment phase. Fourteen patients were discontinued from the protocol during the acute treatment phase due to lack of therapeutic response (10 patients) and/or intolerable side effects (4 patients).

Sixty patients entered the continuation treatment phase. Seventeen of these patients were discontinued from the protocol during this phase, predominantly for intolerable side effects (12 patients) or for administrative reasons (5 patients).

Forty patients reached the maintenance treatment phase and were randomized into double-blind treatment. Twenty-seven of these patients were discontinued prematurely (less than 2-years participation in the maintenance treatment phase). Two patients have completed 2 years, and 11 patients are currently still participating in the maintenance treatment phase. Reasons for early discontinuation from the maintenance treatment phase included: re-emergence of symptoms (18 patients); moved away, but well, at the time of discontinuation (2 patients); unrelated medical problems (3 patients); and intolerable phenelzine side effects (4 patients). Table 1 shows the number of patients in each treatment group who were discontinued from the maintenance treatment phase for re-emergence or exacerbation of symptoms.

Most of the patients who experienced re-emergence of symptoms in ≤ 2 months were in the placebo group. Of the four patients with re-emergence of symptoms after >2 months, one was receiving placebo, none were receiving phenelzine 45 mg/day, and three were receiving phenelzine 60 mg/day. These data suggest a trend ($p = 0.12$) that a standard therapeutic dose of phenelzine is an effective maintenance treatment for preventing, or delaying, a return of depressive symptoms in patients who respond successfully to treatment with phenelzine for 5–6 months.

There were no significant differences in age or length of index episode between patient completers, patients with re-emergence of symptoms in ≤ 2 months (relapse), or patients with re-emergence of symptoms in >2 months (recurrence). The mean length of double-blind treatment was 5.8 weeks for patients with relapse, compared to 23.5 weeks for patients with a recurrence. The mean

length of the index episode from onset to relapse was 13 months.

The emergence of phenelzine side effects was a significant cause for early discontinuation from all three treatment phases. Table 2 lists the side effects reported by discontinued patients during each of the three phases. In nearly all cases the depressive symptoms had shown a favorable response to treatment, but the severity of the side effects caused sufficient discomfort to justify discontinuation of phenelzine.

Discussion

It has been estimated that an average of 65 percent of depressed patients have some degree of relapse within the first year following an index episode (Klerman, 1978). This preliminary report of interim findings from an ongoing study of the safety and efficacy of maintenance MAOI therapy suggests that patients who successfully respond to treatment with phenelzine may benefit from long-term maintenance treatment. Most patients with early re-emergence of symptoms after treatment with phenelzine for 5–6 months were in the placebo maintenance group.

There was no significant difference in the length of the index depressive episode between the patients with re-emergence of symptoms ≤ 2 months (relapse) and >2 months (recurrence). These findings are consistent with a typical cycle length of 1 year or longer for a major depressive episode in the majority of patients with recurrent major depression.

Interestingly, over 80 percent of patients with RDC major depression responded initially to treatment with phenelzine; but, 20 of the 79 patients (25%) who entered the study ultimately discontinued treatment because of troublesome side effects (4 patients during acute treatment, 12 during continuation treatment, and 4 during maintenance treatment). Three of the four patients discontinued from the 2-year maintenance phase experienced the onset of adverse side effects during the continuation phase of treatment. These three patients had excessive weight gain associated with carbohydrate craving and hyperphagia which resulted in weight gains of 30 to 45 lbs. Most of the patients who discontinued from treatment prematurely were reluctant to stop phenelzine therapy because of an otherwise excellent therapeutic response.

Psychotherapeutic Approaches to Treatment of Recurrent Unipolar Depression: Work in Progress[1]

Ellen Frank, Ph.D.,[2] and
David J. Kupfer, M.D.[2]

Although much of the recent treatment research in depression has focused on comparisons of psychotherapy with pharmacotherapy (Kovacs et al., 1981; Elkin et al., 1985), few studies have explored the efficacy of combined treatment with this population. The work of Weissman and colleagues (Weissman et al., 1974; Weissman et al., 1978) is a notable exception. The present paper addresses acute and, in particular, continuation treatment results with a large group of recurrent unipolar depressives offered a combination of imipramine and Interpersonal Psychotherapy (IPT) (Klerman et al., 1984). The pace of treatment response, the low frequency of adverse effects, the low relapse rate, and the high level of patient adherence to the treatment protocol are explored as they relate to the combined treatment strategy.

Method

Patients between the ages of 21 and 65, suffering from a major depressive disorder were entered into the Maintenance Therapies in Recurrent Depression protocol if the index episode was at least their third episode of major depression and the immediately previous episode had occurred within the last 2½ years. Minimum Hamilton Rating Scale for Depression (HRS-D) (≥15) and Raskin Severity of Depression and Mania Scale (≥7) scores were also required. Following a 2-week, drug-free period, severity of depression was reevaluated and patients remaining symptomatic were given a complete initial assessment including biological (all-night sleep EEG and neuroendocrine studies) and psychosocial (e.g., social adjustment, social support) measures.

All patients then received the same acute treatment regimen: imipramine (150–300 mg per day) and IPT offered weekly for 12 weeks, biweekly for 8 weeks, and monthly thereafter. At the point when patients had maintained an HRS-D score of ≤7 and a Raskin score of ≤5 for 3 weeks, a second (continuation) biological and psychosocial evaluation was completed. Patients remained in continuation treatment for an additional 17 weeks, during which both Hamilton and Raskin scores and imipramine dose were required to remain stable. A third (premaintenance) evaluation was then conducted, after which patients were randomly assigned to one of the five maintenance treatment cells (psychotherapy alone, psychotherapy plus active medication, psychotherapy plus placebo, medication clinic plus active medication, or medication clinic plus placebo) for 3 years or until they experienced a recurrence of illness (*see* Figure 1).

Subjects

This report is based on the first 119 patients to enter the study. As can be seen in Table 1, the group of 119 patients consisted of 27 males and 92 females with a median age of 39.3 and a median age of onset of illness of 24.6. The mean duration of the index episode at the point of entry into the study was 23.4 weeks. Although a minimum baseline HRS-D rating of 15 was required for entry, most patients had considerably higher ratings; the mean rating on entry was 22.7. Three patients had had two previous episodes of major depressive disorder, while the remaining 116 had three or more previous episodes (median = 4.2). This determination was based on the Schedule for Affective Dis-

orders and Schizophrenia data obtained on admission to the study and on the Lifetime History of Affective Disorder obtained during the clinical remission period. Of these patients, over 90 percent remained in the study for the first 4 months; almost 62 percent of these developed a clinical response within 16 weeks (Frank et al., 1984). Fifty-seven of the 119 patients entered the maintenance phase.

Results

Response to Acute Treatment

Early in the study we observed three distinct patterns of response to the combined regimen of imipramine and IPT. About a third of the patients appeared to show a good remission of symptoms within 3 to 4 weeks and were fully remitted by 8 weeks. Another third had a much more variable course and required several months before they were regularly rated at levels consistent with a clinical remission. A final third appeared only partially responsive to the imipramine-IPT combination.

In order to assess the differences in rapidity of clinical response in this population, we developed a methodology to test the accuracy of the observations described above. At the end of 16 weeks of acute treatment patients were classified as Normal Responders, Slow Responders, or Nonresponders. Treatment response categories were determined in the following fashion. If the HRS–D at 8 weeks was less than or equal to 7, and the HRS–D at 16 weeks was less than or equal to 7, and the change score at 16 weeks was greater than or equal to 50 percent, then a patient was classified as a Normal Responder. However, if these criteria were met, but the HRS–D at 12 weeks was greater than or equal to 10 (signifying some level of clinical exacerbation), then an individual was classified as a Slow Responder. A patient could also be classified as a Slow Responder if the HRS–D was greater than 7 at 8 weeks and if the HRS-D at 16 weeks was between 8 and 10, but the total change score was greater than or equal to 60 percent. A third manner in which a patient could be classified as a Slow Responder was if none of the above criteria was met, but the HRS–D at 16 weeks was less than or equal to

7. If none of the aforementioned criteria for Normal or Slow response was met, the patient was considered a Partial or Nonresponder. Of the first 119 patients, 35 (29.4%) were classified as Normal Responders, 32 (26.9%) were classified as Slow Responders, and 28 (23.5%) were classified as Partial or Nonresponders. Twenty-three patients (19.3%) had to be terminated from the study prior to 16 weeks because of serious clinical worsening, intolerable side effects, or failure to comply with the study protocol. One patient, who developed an allergy to the pill coating and had to be restarted on a different formulation, could not be classified.

Absence of Adverse Effects

In our study we have purposely attempted to use a high dosage of imipramine during acute treatment and to maintain that dosage as individuals enter continuation treatment. The average dose of patients entering maintenance treatment was approximately 225 mg. This study, then, addresses the question of whether dosages higher than 150 mg of antidepressant are well tolerated, and whether they result in increased treatment efficacy.

An important issue in the assessment of the effectiveness of increased dosages in this study was the safety of these higher dosages in terms of their side effects. We assessed adverse effects of medication through the Somatic Symptoms Checklist, a scale developed specifically for use in this study. The scale consists of 20 somatic complaints frequently reported as side effects of imipramine treatment. Subjects were queried prior to the start of drug treatment and at each visit during treatment regarding the presence or absence of each symptom, rating the severity of the symptom as 0 (not present), 1 (present but tolerable), or 2 (present and causing significant distress), yielding a possible range of 0 to 40 for a total score.

The results presented in Table 2 indicate that overall the higher doses of imipramine used in this study do not adversely affect patients in terms of the side effects experienced. In examining these results, it would appear that side effects were a relatively minor consideration at week 16 and played a minor role during continuation and at the premaintenance evaluation. In fact, very few patients withdrew from the study because of adverse drug effects, and those that did also had accompanying medical problems. The

*Chi-square significant at at least $p < .05$.

percentage of patients reporting the presence of somatic symptoms did not deviate significantly across the three treatment periods. In fact, a number of somatic symptoms showed a decrease at premaintenance when compared to the earlier treatment phases. For example, the incidence of dry mouth, often an acute somatic symptom, decreased over time as did increased perspiration. In contrast, dizziness and nausea/vomiting increased over time.

Another way of examining these somatic symptoms is to explore what percentage of these patients reported a total score of 6 or more out of a possible 40. As Table 2 shows, the percentages of patients scoring 6 or more at pretreatment, week 16, continuation, and premaintenance were 64, 47, 35, and 45 percent, respectively. The median scores at those four time periods were 6.8, 4.8, 4.6, and 4.8, respectively. We conclude from these results that the frequency of adverse effects did not alter the course of the first 6 to 9 months of treatment in a major way.

Relapse Rate

The problems of defining and achieving recovery in recurrent disorders and avoiding relapses in such patients are now of major importance to clinicians, epidemiologists, and biological investigators. One of the first hurdles in developing this investigative expertise is defining what one means by "recovery" and "relapse." While there is considerable disagreement as to whether relapse represents an exacerbation of the symptomatology of an ongoing and incompletely treated episode after a recovery period or represents a new episode, there is agreement that the symptoms which constitute a relapse must follow a period of remission and must meet the criteria for either a major episode of depression or minor depression. Naturalistic studies have been available for 10 to 20 years on this topic (Angst, 1973; Zis & Goodwin, 1979). The recent reports coming from the NIMH Collaborative Study on the Psychobiology of Depression have added substantially to the database on relapse in major depression, especially in those individuals who have repeated episodes of depression (Keller et al., 1982a; Keller et al., 1982b; Keller et al., 1983). Data from these collaborative studies have demonstrated that individuals with three or more episodes of depression may, in fact, have a relapse rate as high as 40 percent within 12 to 15 weeks after recovery. While these data are revealing, there has been an increasing need for data on the rate of relapse in controlled treatment trials. Most studies indicate that during active drug treatment there is approximately a 22 percent relapse rate, and that under placebo or no pill conditions rates of relapse may reach 50 percent or greater (Prien & Kupfer, 1986). Our current investigation utilizing both pharmacologic and psychotherapeutic interventions offers a unique opportunity to examine the issue of relapse in recurrent depression in a controlled treatment trial.

Relapse in this investigation was defined as meeting the criteria for a major depressive episode after at least 8 weeks of recovery (Keller et al., 1982a). Of the 119 patients, 80 percent remained in the study for the first 4 months. Using our criterion of a Hamilton score of ≤ 7, 67 of these patients had developed a clinical response within 16 weeks. Seventy-seven of the 119 patients eventually completed the acute treatment phase and entered the continuation phase; 59 of the 77 patients completed the continuation phase and entered the maintenance phase of the study. Of the remaining 14 patients who reached continuation but who failed to complete the 20 weeks of continuation, 9 patients suffered a recurrence of symptoms—4 patients showed a recurrence of symptoms within 4 weeks of entering continuation (2 within 10 days, 1 within 2 weeks, 1 within 4 weeks), and 5 patients suffered a relapse after 8 weeks of recovery. Therefore, using the criterion of 8 weeks of recovery, there are only five patients who met our criterion for a relapse. If one utilizes a liberal definition of relapse, then 15.3 percent of this sample suffered a recurrence of symptoms. However, if one uses the criterion of a minimum of 8 weeks, then 8.5 percent of this sample suffered a relapse. Five patients did not complete the continuation phase and left the study in a state of clinical symptomatic remission—one patient who unexpectedly moved out of state, three patients who dropped out of the study (unilateral termination), and one patient who had sufficiently adverse side effects to withdraw from the study.

The paucity of relapses (five) necessitates a descriptive rather than a statistical approach. The mean length of time for the patient group going into relapse after entering continuation was 21.4 weeks and the median was 16.9 weeks (one patient stabilized at several different points during continuation, thus necessitating additional symptom-free periods in continuation).

The current literature on naturalistic follow-up suggests that the cumulative rate of relapse after recovery for those individuals with primary depression is approximately 15 percent at 6 months and 22 percent at 1 year (Zis & Goodwin, 1979; Keller et al., 1982a). While these patients met criteria for primary depression, they represent patients who, for the most part, had fewer than three episodes. A further refinement of the most recently published analyses indicates that 11 percent of patients with fewer than three episodes had a relapse within 12 to 15 weeks, but 43 percent of patients with three or more episodes suffered a relapse by the 12th week. Thus, recurrent unipolar patients not entered in a controlled treatment trial may very well experience a 40 percent relapse rate within 4 to 5 months following recovery. These data from the Collaborative Study on the Psychobiology of Depression are consistent with the recent review of continuation treatment recently compiled by Prien and Kupfer (1986) which demonstrates that the relapse rate for active drug versus placebo conditions is 22 percent versus 50 percent.

Our data suggest that the addition of psychotherapy as well as an educational workshop offered to our study participants and their families within the umbrella effort of a major research protocol may reduce the rate of relapse to a rate below 10 percent. While this finding needs to be replicated (the second half of the sample for this investigation will offer us the opportunity to do that), it should be recognized that the combination of psychotherapy and pharmacotherapy may offer the best approach to reducing relapse following recovery in the continuation phase of treatment.

Treatment Adherence in Premaintenance Phases

Many of the ingredients which relate to overall compliance or adherence have been addressed earlier in this report. As shown in Table 3, compared to previous studies, our "noncompliance" rate has remained very low over the duration of the study. Although evidence has accumulated that the drop-out rate for pharmacotherapy trials is higher than for psychotherapy, this rate cannot be attributed strictly to the inclusion of psychotherapy in the treatment approach. Rather, we would argue that the overall clinic approach as offered in our Depression Prevention Clinic and the psychoeducational workshop foster a climate of clinician/patient/family member alliance which leads to joint participation in the protocol. Indeed, patients who must be dropped from the protocol because of a failure to respond during the acute or continuation phases or who experience recurrences during maintenance have been unwilling to leave the clinic and most have been followed within the Western Psychiatric Institute and Clinic's Mood Disorders Module.

Summary

While a number of reasons account for the failure of all patients to reach the maintenance phase in this research design, three points are worthy of mention. The larger

than expected group of treatment nonresponders (i.e., not responsive *enough* to meet study remission criteria) is worthy of attention since this figure of 22 percent may represent a factor related to the clinical characteristics of the entire group at entrance. This is, to our knowledge, the first time any research group has attempted to study a population with a *minimum* of three episodes. If it is true, as Keller et al. (1986) have suggested, that with each additional episode a certain percentage of recurrent patients go on to have a chronic course, the entry criteria for the study may have selectively biased the study population, increasing the percentage of patients who failed to remit. Another factor which may have inflated the apparent rate of treatment failure is the exceptionally high rate (90%) of patient retention. Many of the 22 percent of treatment failures in this study would likely have been represented in the drop-out rates (25 to 50%) reported in other studies. The lower than expected rate of relapse during continuation, the low frequency of adverse effects, and the high rate of patient retention are also worthy of note. We view these as a direct result of the inclusion of psychotherapy as an integral part of the initial treatment phases and a result of the collaborative atmosphere developed in the Depression Prevention Clinic among clinicians, patients, and family members.

The Pitfalls of Serotonin Precursors as Challengers in Hormonal Probes of Central Serotonin Activity

Herman M. van Praag, M.D., Ph.D.,[1] Carmen Lemus, M.D.,[1] and Rene Kahn, M.D.[1]

Hormonal Probes of Central Serotonergic Activity

The response of a serotonin mediated function to a serotonin (5-hydroxytryptamine; 5-HT) agonist or antagonist has been used as a probe of the functional state of central 5-HT-ergic systems (Lemus & van Praag, 1986). Hormone release has been generally used as a 5-HT mediated function. The strategy is based on two assumptions; first, the challenger is 5-HT selective, and second, in the control of the marker-hormone 5-HT neurons play a significant role. In humans the two prerequisites are interdependent, in that the only way to ascertain the 5-HT-ergic involvement in a hormone's release is to measure its level in blood and cerebrospinal fluid (CSF) after administration of a 5-HT influencing drug. Hence the availability of 5-HT selective compounds is crucial. Challengers most frequently used have been the 5-HT precursors tryptophan and 5-hydroxytryptophan (5-HTP); the hormones most frequently measured are prolactin, cortisol, and growth hormone.

The issue here is the validity of hormonal 5-HT probes using 5-HT precursors as challengers.

Prolactin

Tryptophan

High doses of ℓ-tryptophan cause a release of prolactin. Charney et al. (1982) administered 7 g intravenously (i.v.) over a 20-minute period and observed a marked increase in serum prolactin, although the percent increase above baseline ranged widely (79 to 1100%). Likewise after i.v. administration of 5 to 10 g ℓ-tryptophan, MacIndoe and Turkington (1973) reported a substantial increase in plasma prolactin. Infusion of 4 g or less failed to produce consistent stimulation of prolactin secretion. After large oral doses (10 g) plasma prolactin rose but not significantly so (Woolf & Lee, 1977). Smaller oral doses of ℓ-tryptophan failed to induce prolactin release.

The central question is whether the prolactin-releasing effect of high i.v. doses of ℓ-tryptophan can be attributed to activation of 5-HT-ergic systems. There is reason for doubt. An oral dose of 5 g ℓ-tryptophan causes a significant increase in post-probenecid 5-hydroxyindoleacetic acid (5-HIAA) in CSF, indication of an augmented metabolism of 5-HT (van Praag, 1983). We demonstrated that the same dose of ℓ-tryptophan, administered i.v. over a 30-minute period, does not increase post-probenecid CSF 5-HIAA any further (Figure 1). The route of administration, however, does make a difference with regard to CSF concentration of homovanillic acid (HVA), the main dopamine (DA) metabolite, and 3-methoxy-4-hydroxyphenyl glycol (MHPG), the main CNS metabolite of noradrenaline (NA) (Figure 1). Oral administration of 5 g ℓ-tryptophan does not influence the HVA and MHPG concentration in CSF after probenecid administration. Both concentrations, however, diminish significantly if the i.v. route of administration is used, indicating a decrease in DA and NA metabolism. A likely explanation for this latter phenomenon is decreased influx of tyrosine in the CNS, due to competition with tryptophan for the same carrier mechanism (Wurtman, 1982; Wurtman et al., 1981). Rather than induced by an increased serotonergic "tone," the rise in plasma prolactin could have been caused by a decrease in DA synthesis and availability. It is true that MacIndoe and Turkington (1973) reported that methysergide inhibited the prolactin response to i.v. ℓ-tryptophan, but methysergide is not a selective 5-HT antagonist and has, e.g., antihistamine properties as well (Stone et al., 1961).

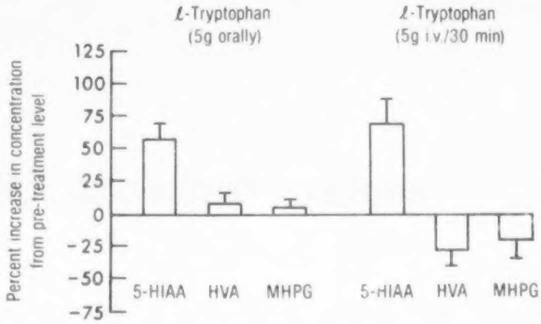

FIGURE 1. Percent increase in the concentration of 5-HIAA, HVA, and MHPG in lumbar CSF after administration to 5 test subjects of a single dose of 5 g ℓ-tryptophan either orally or i.v. 5-HIAA concentration rose significantly on both occasions and to the same extent. After oral administration, the changes in HVA and MHPG were insignificant; after i.v. administration both concentrations dropped significantly. Lumbar CSF was withdrawn after probenecid loading (5 g/5 hr), 8 hr after starting the load.

5-Hydroxytryptophan

Likewise, with 5-HTP it seems that only large doses influence prolactin release. Oral administration of 200 mg of the racemic mixture does not influence the plasma level of prolactin (Beck-Peccoz et al., 1976; Meltzer et al., 1983). The ℓ-isomer of 5-HTP, 200 mg orally, in combination with a peripheral decarboxylase inhibitor (PDI) had no effect either (Westenberg et al., 1982).

Administration of 50 mg i.v. of ℓ-5-HTP-ethyl-acetate after pretreatment with a PDI did result in a *decrease* of plasma prolactin (van Praag et al., 1976), while 200 mg of the same compound, also after pretreatment with the same PDI, induced a *rise* in prolactin release (Lancranjan et al., 1977). Are these effects to be explained in serotonergic terms?

We demonstrated that 200 mg ℓ-5-HTP orally in combination with a PDI gives rise not only to a substantial rise of post-probenecid CSF 5-HIAA, but to a significant rise of CSF HVA and MHPG as well (Figure 2), indicating that both 5-HT and catecholamine (CA) metabolism is increased (van Praag, 1983; van Praag & Lemus, 1986). We hypothesized the increase in CA metabolism to be a compensatory response to formation of 5-HT in CA-ergic neurons acting there as a false transmitter. The net effect of the two opposing effects: formation of false transmitter leading to decreased CA-ergic function, and increased CA synthesis resulting in increased CA-ergic function, is probably augmentation of CA-ergic activity (van Praag, 1984). The decrease in prolactin release we observed after i.v. 5-HTP could conceivably have been the result of increased DA activity. Perhaps the fourfold higher dose administered by Lancranjan et al. (1977) did set a 5-HT-ergic mechanism into action.

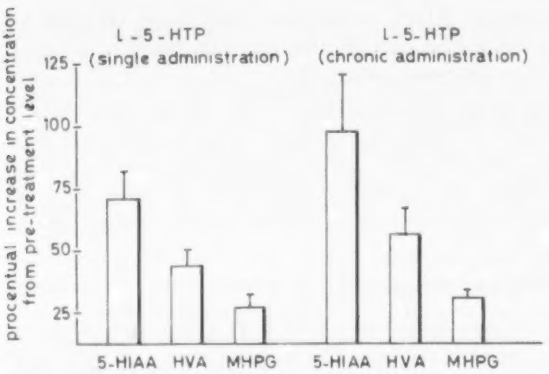

FIGURE 2. Percent increase in the concentration of 5-HIAA, HVA, and MHPG in lumbar CSF after administration to test subjects of a single dose of ℓ-5-HTP (200 mg orally) and after administration of the same dose for 1 week. In the acute experiment, the patients were pretreated with carbidopa (150 mg/day) for 3 days. In the chronic experiment, ℓ-5-HTP was combined with carbidopa in the same dose. In all cases, the increase in concentration in relation to the medication-free period was significant. Lumbar CSF was withdrawn after probenecid loading (5 g/5 hr), 8 hr after starting the load (van Praag, 1983).

Cortisol

Tryptophan

Modlinger et al. (1980) reported a significant increase of plasma ACTH and cortisol after an oral load of 10 g tryptophan in 11 normal volunteers. Activation of central 5-HT-ergic mechanisms is a conceivable mechanism, but there are others to be considered. First is increased adrenal steroid production due to a surplus of 5-HT formed in the periphery from tryptophan (Verdescu et al., 1961). This mechanism, however, is unlikely since ACTH production is also increased. A second possible mechanism for the increased release of ACTH and cortisol is decreased availability of NA, due to competition of tyrosine and tryptophan for transport into the CNS (Wurtman, 1982). The CRF/ACTH/cortisol axis is normally under β-adrenergic inhibitory control. Down-regulation of that mechanism would stimulate ACTH and cortisol release (Checkley, 1980; Nakai et al., 1973).

Several observations support the last mentioned hypothesis. ℓ-Tryptophan in relatively low doses, 2 to 5 g orally, does not significantly alter plasma cortisol (Hyyppa et al., 1979; Westenberg et al., 1982). However, it does increase post-probenecid 5-HIAA, without influencing CSF HVA and MHPG (van Praag, 1983; Westenberg et al., 1982). Higher doses, 5 g i.v. administered, while not further increasing CSF 5-HIAA, decreased CSF HVA and MHPG (Figure 1). These findings are hard to reconcile with 5-HT-ergic stimulation of cortisol release and suggest a CA-ergic mechanism.

The situation becomes confusing if one acknowledges the findings of Woolf and Lee (1977) who administered, like Modlinger et al. (1980), 10 g ℓ-tryptophan orally, but reported a *decrease* in plasma cortisol. Moreover, tryptophan blunted the ACTH and cortisol response to insulin hypoglycemia. They concluded that 5-HT is apparently a potent *inhibitor* of hypothalamic CRF in man. Peak plasma tryptophan levels were considerably lower in their experiment than in those of Modlinger et al. (1980) but well within the range we found to be effective in increasing CSF 5-HIAA.

5-Hydroxytryptophan (5-HTP)

The 5-HTP data are likewise controversial. Imura et al. (1973) administered 150 mg 5-HTP orally (isomer not mentioned) without PDI and observed a significant rise of plasma cortisol. Neither Westenberg et al. (1982) nor Meltzer et al. (1984) could replicate their findings, the former using much greater quantities of 5-HTP (200 mg of the ℓ-isomer with a PDI) than the latter (200 mg of the racemic mixture without PDI). In a group of patients suffering from major depression, however, Meltzer et al. (1984) found a rise in plasma cortisol, while we failed to find a response in this group either (Westenberg et al., 1982, 1984). The cortisol response to 5-HTP in depression was hypothesized to indicate hypersensitivity of postsynaptic 5-HT receptors.

A possible explanation for the discrepancy between the findings of Meltzer et al. and ourselves is the following. As discussed in the section on prolactin, the 5-HTP regimen we used increases both 5-HT and CA metabolism (van Praag, 1983) (Figure 2), and probably increases CA-ergic function (van Praag, 1984). Increased NA function would tend to decrease cortisol release and obscure a possible stimulating effect of surplus 5-HT in depressed patients. We found no evidence that cortisol release is induced by the PDI alone.

Against a serotonergic explanation of the increased cortisol response to 5-HTP observed in depression by Meltzer et al. (1984) speaks our observation that the dose of 5-HTP we administered definitely increases CSF 5-HIAA, while the low dose he used does not (van Praag, unpublished) (Figure 3). That is not to say that 5-HT metabolism in the CNS is not augmented by low doses of 5-HTP but that proof that that occurs is lacking.

Growth Hormone

Tryptophan

Most investigators but not all (MacIndoe & Turkington, 1973) have reported an increase in plasma growth hormone levels after administration of ℓ-tryptophan (Fraser et al., 1979; Muller et al., 1974; Westenberg et al., 1982; Woolf & Lee, 1977). The rise is modest and variable, and from the published data no clear dose/response relationship can be deducted. After a massive oral dose of 10g ℓ-tryptophan orally, the growth hormone level does not rise more than from 0.5 ± 0.2 ng/ml to 8.9 ± 3.4 ng/ml (Woolf & Lee, 1977). After a massive i.v. dose of 8.4 g, the rise was of comparable magnitude (Charney et al., 1982). A constant finding is that not all test persons respond to a tryptophan challenge.

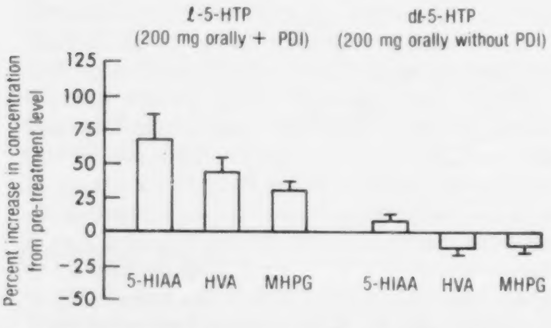

FIGURE 3. Percent increase in the concentration of 5-HIAA, HVA, and MHPG in lumbar CSF after administration to 5 test subjects of either a single dose of 200 mg ℓ-5-HTP after 3 days pretreatment with a peripheral decarboxylase inhibitor (PDI), or a single dose of 200 mg of the racemic mixture without PDI. Under the former regimen all three concentrations rose significantly. Under the latter circumstances they did not. Lumbar CSF was withdrawn after probenecid loading (5 g/5 hr), 8 hr after starting the load.

5-Hydroxytryptophan (5-HTP)

Large doses of 5-HTP do stimulate growth hormone release. Administration of 200 mg i.v. of ℓ-5-HTP in combination with a PDI induced a rise from <2 ng/ml to 32.0 ± 8.8 ng/ml (Lancranjan et al., 1977). The same dose orally prompted a tiny but significant increase from 1.7 ± 1.6 ng/ml to 2.6 ± 2.3 ng/ml (Westenberg et al., 1982). Smaller doses of 5-HTP with or without PDI have generally no effect (Ansseau et al., 1983; Handwerger et al., 1975; Muller et al., 1974). Only Imura et al. (1973) reported a rise of growth hormone of more than 5 ng/ml in six of eight subjects tested after no more than 150 mg 5-HTP (ℓ-isomer or racemic mixture is not stated) orally without PDI.

As explained above, 5-HTP in large doses stimulates CA turnover and the release of growth hormone could be attributed to that effect rather than to increased 5-HT availability. Supporting evidence is provided by a preliminary report of Imura et al. (1973)—reported by Checkley (1980)—that the growth hormone response to 5-HTP is blocked by the α-adrenoreceptor blocker phentolamine.

Discussion

No 5-HT precursor-mediated hormonal test can claim to be a valid probe of central 5-HT-ergic activity. The reason is that neither tryptophan nor 5-HTP are 5-HT selective and do influence CAs as well. The effect on CA becomes generally manifest after large amounts of the precursor, but most studies indicate that those are needed for a hormonal response to be observed. It is therefore impossible to decide whether the observed hormonal changes are 5-HT or CA mediated.

In attempts to develop a hormonal 5-HT probe, synthetic 5-HT agonists and antagonists have also been used. The results so far have been disappointing (van Praag et al., 1986) and for several reasons. Non-selectivity of the challenger is one of them. Using the same drug in different doses and routes of administration, not caring to establish proper dose-response relationships is another. Comparability of individual studies is therefore regrettably low.

A peripheral probe of central 5-HT activity, circumventing the need to measure CSF 5-HIAA, would be of great importance for biological studies of depression, suicide, and aggression disorders. A challenge test, however, should not be accepted as a 5-HT probe before: 1) dose-response relationship has been established; 2) studies in humans have rendered influences of the challenger on other monoaminergic systems unlikely; and 3) the hormonal effect of the challenger has been shown to be counteracted by a functional opponent of the challenger.

Summary

5-HT precursors have been used as challengers in hormonal probes of central 5-HT activity. Those tests, however, lack validity because both tryptophan and 5-HTP do influence CA as well, in particular if administered in large quantities; but these are generally needed to obtain a hormonal response. Hence it is impossible to conclude whether the response is 5-HT or CA mediated. Peripheral probes of central 5-HT activity are badly needed, but before being accepted as such, one should make sure that certain minimum requirements have been satisfied.

The Desipramine Cortisol Test—A Selective Noradrenergic Challenge (Relationship to Other Cortisol Tests in Depressives and Normals)

Gregory M. Asnis, M.D.,[1] Carmen Z. Lemus, M.D.,[1] and Uriel Halbreich, M.D.[1]

Introduction

The use of peripheral hormones to provide a "window into the brain" was proposed by Sachar (1975). This was based on the fact that hormone secretion was primarily regulated in the hypothalamus by certain neurotransmitters and peptides. Thus, hormone levels would convey specific neurotransmitter information. The catecholamines—dopamine and norepinephrine—act as neurotransmitters at the hypothalamic level and control the hypothalamic releasing and inhibiting factors that act on the anterior pituitary. By using pharmacologic agents which interfere with catecholamine synthesis or metabolism and concurrently measuring peripheral hormone levels, some conclusions can be made as to the effect of a particular catecholamine on a particular hormone.

We have been mainly interested in cortisol since increased cortisol secretion has been the most consistent neuroendocrine finding in depressive illness. But what neurotransmitter disturbances are associated with cortisol hypersecretion remains unclear.

The secretion of ACTH and cortisol is believed to be under the control of multiple neurotransmitters. The role of each neurotransmitter in relation to the release of these hormones is not well known. Dopamine seems to have no effect on ACTH secretion in humans (Westenberg et al., 1982) although it inhibits ACTH release in rats (Moore, 1978). Studies with serotonin agonists and antagonists implicate this neurotransmitter in the regulation of ACTH, although results have been inconsistent. Some studies have been unable to stimulate ACTH and cortisol release after administration of 5-hydroxytryptophan (5-HTP) (Westenberg et al., 1982; Wirz-Justice et al., 1976) or L-tryptophan (Westenberg et al., 1982), while others have reported increases in ACTH and cortisol (Meltzer et al., 1983; Modlinger et al., 1980). Results with administration of serotonin antagonists are more uniform and point to an excitatory influence. Cyproheptadine has been shown to inhibit the basal and nocturnal rise of cortisol (Chihara et al., 1976; Delitala et al., 1975) as well as the cortisol secretion secondary to insulin-hypoglycemia (Plonk et al., 1974).

As for the noradrenergic system, it is generally believed that α-adrenergic receptors have a stimulatory effect and β-adrenergic receptors have an inhibitory effect on ACTH secretion. α-Agonists such as methoxamine stimulate ACTH secretion while the α-blocker phentolamine inhibits the ACTH response to methoxamine and to insulin-hypoglycemia (Nakai et al., 1973). On the other hand, the β-blocker propranolol augments the ACTH response to hypoglycemia (Nakai et al., 1973). The effect of the noradrenergic system as a whole is believed by most to be inhibitory (Jones, 1978) although there are some proponents of a stimulatory action of norepinephrine on ACTH (Besser et al., 1969; Nakai et al., 1973).

As highlighted by this brief review of cortisol regulation, cortisol hypersecretion in depressive illness may be a final common pathway encompassing diverse groups of depressives with disturbances in multiple neurotransmitters. Thus, it seemed most important to utilize selective neurotransmitter probes to help evaluate cortisol secretion in man and possibly identify more homogeneous groups of depressives. In particular, a noradrenergic probe seemed warranted since NE is one of the neurotransmitters thought to be involved in the regulation of cortisol and is one of the main neurotransmitters im-

plicated in depressive illness (Bunney & Davis, 1965; Schildkraut, 1967).

In the past we have published extensively on the cortisol response to dextroamphetamine in normals and depressives. A blunted cortisol response to dextroamphetamine in depressives was a consistent finding (Halbreich, 1981; Sachar et al., 1980, 1981). Interpretation of this observation was complicated by the fact that dextroamphetamine, besides affecting norepinephrine, also releases dopamine, phenylethylamine, endorphin, and possibly serotonin (Halbreich et al., 1982; Moore, 1978). The latter has also been suggested to stimulate cortisol release, thus complicating any interpretation of mechanisms for the cortisol release to amphetamine (Checkley, 1980). Furthermore, since cortisol is a stress-sensitive hormone and amphetamine has significant behavioral effects in subjects, it is possible that cortisol differences between depressives and nondepressives were related to differences in their behavioral responses. This seems unlikely, though possible, since methylphenidate has been reported to induce similar behavioral changes as amphetamine without affecting cortisol (Brown et al., 1977). Ideally, the use of a noradrenergic agonist which is highly selective and does not cause significant mood or behavioral changes would be a most appropriate tool in assessing noradrenergic effects on cortisol secretion in man (depressives and nondepressives).

For this reason we were most interested in investigating the cortisol response to a relatively specific noradrenergic agonist, desipramine (DMI). Furthermore, we wanted to evaluate whether the cortisol response to DMI in depressives differed from normals as is the case with many other measures of cortisol secretion (e.g., DST and basal plasma cortisol). We hoped that the DMI-cortisol test would identify a group of depressives which in theory might be homogeneous (with a possible noradrenergic deficit) allowing for identification of particular clinical correlates which other tests of cortisol secretion have failed to do. Also, we wanted to compare the DMI cortisol response to other measures of cortisol secretion (mean 1 to 4 p.m. plasma cortisol test and the 1 mg DST) in depressives and normals. Thus, a pilot study was initiated. Preliminary findings of this project have been reported recently (Asnis et al., 1985).

Pilot Study

Thirteen endogenous depressives (8 females and 5 males), 23 to 64 years old (mean age 38.7 SE 2.8 years), and 20 normal controls (10 females and 10 males), 18 to 52 years old (mean age 33.0 SE 2.6 years), gave informed consent and participated in the study. Although subjects were not matched for age and sex, there were no significant differences in age (t = 1.50, 2-tailed t-test), nor frequency of sex ($\chi^2 = 0.423$). Patients were given a SADS interview and diagnosed by RDC criteria (Endicott & Spitzer, 1978; Spitzer et al., 1978) for major depressive disorder, endogenous subtype; normal controls were judged free of any psychiatric disorder after receiving a SADS interview. All patients had a Hamilton Depression score of ≥ 18 (mean Hamilton score 25.5 SE 2.1) and were free of psychotropics for a minimum of 10 days. In addition to the RDC diagnosis of major depressive disorder, endogenous subtype, which all 13 patients had, 4 patients had a psychotic depression, 3 had bipolar depression, and 3 had a secondary depression (2 secondary to alcoholism—abstinent from alcohol for at least 6 months—and 1 secondary to panic disorder).

DMI Procedure

All subjects fasted from midnight and awakened at 0700 h. A butterfly needle was inserted in the forearm vein at 0900 h and kept patent with sterile saline. After obtaining three baseline samples (4 cc each at 15 min intervals), 75 mg i.m. DMI was given in the gluteal muscle followed by sampling (4 cc) every 15 min for plasma cortisol for 120 min. All samples were centrifuged and then frozen at −20°C to await analysis.

Other Cortisol Assessments (the Mean 1–4 Plasma Cortisol Test and the 1 mg DST) Administered 5 Days After the DMI Procedure

The mean 1–4 p.m. plasma cortisol test is an integrated measure of plasma cortisol secretion since it has been shown to be highly correlated to the mean 24 h plasma cortisol in normals and depressives (Halbreich et al., 1981, 1982). All subjects had an angiocatheter inserted in a forearm vein prior to 1130 h (with sampling every 30 min for plasma cortisol). Subjects remained supine during the test and were all given breakfast at 0730 h and a light lunch at 1030 h; no snacks or naps were permitted. The average of the seven 30-minute samples from 1 p.m. to 4 p.m. was the mean 1 p.m.–4 p.m. plasma cortisol level.

The 1 mg DST is a test widely utilized in endocrinology and psychiatry. Dexamethasone, a synthetic corticosteroid many times more potent than cortisol, normally turns off endogenous cortisol secretion for 24 to 48 h by affecting feedback receptors. Investigators have found that approximately two-thirds of endogenous depressives failed to suppress cortisol. (For review *see* Arana et al., 1985.)

All the subjects were given 1 mg of dexamethasone to be taken orally at 11:00 p.m. (the same day of the 1–4 p.m. plasma cortisol test). The following day a postdexamethasone plasma cortisol level was obtained at 8 a.m., 4 and 11 p.m. A plasma postdexamethasone cortisol greater than 5 µg/dl at any time was used to define non-suppression to dexamethasone.

Cortisol Assay

All plasma samples were analyzed in duplicate by a modified competitive binding method, using Florisil to separate bound from free fractions (Murphy, 1967). Intra- and interassay coefficients of variation of duplicate samples were 2.8 and 9.0 percent, respectively. All samples from a given subject were assayed in the same run.

Results

The cortisol response to DMI over 120 min in both endogenous depressives and normal controls is seen in Figure 1. A repeated measures analysis of variance was performed on the group and time effects and their interaction. The group effect was not significantly larger than the between subject effect (F = 1.06, df 1/31, $p = 0.31$); there was a significant time and a group × time interaction (F = 13.65, df 10/307, $p = .001$ and $F = 2.68$, df 10/307, $p = .003$, respectively). The means of individual cells were compared at equivalent time points between groups as planned comparisons. It was found that these means were not significantly different at time points prior to 45 min or subsequent to 75 min. Significant differences did occur between 45 to 75 min ($p = .01$ at 45 min, $p = .02$ at 60 min, $p = .0001$ at 75 min). These data were also analyzed as percent increase above baseline cortisol; the data demonstrated similar differences between groups and with significant differences at the same time points (45 to 75 min).

The cortisol change scores (post–DMI cortisol minus baseline cortisol) of endogenous depressives and normal controls at the significant times (45 to 75 min) were evaluated for cutoff values which would best discriminate endogenous depressives from normal controls. A cutoff of 1.5 µg/dl increase above baseline at 45 min most significantly discriminated between normals and depressives. This criterion was the same as the one found best in discriminating endogenous depressives from normal controls utilizing the dextroamphetamine cortisol test (Sachar, 1981). The Δ45 min cortisol with a cutoff of 1.5 µg/dl identified 7 of 13 depressives and 1 of 20 normals (Fisher Exact Test=.003) (Figure 2).

It was decided on the basis of the repeated measures effect to convert the post-DMI cortisol levels to change scores from baseline (time 0) in order to examine the effect of

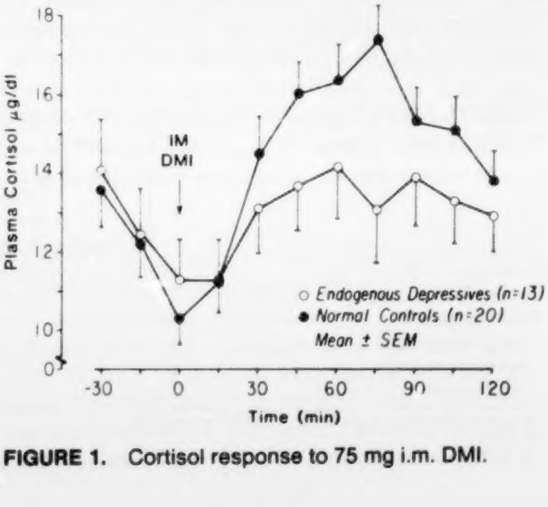

FIGURE 1. Cortisol response to 75 mg i.m. DMI.

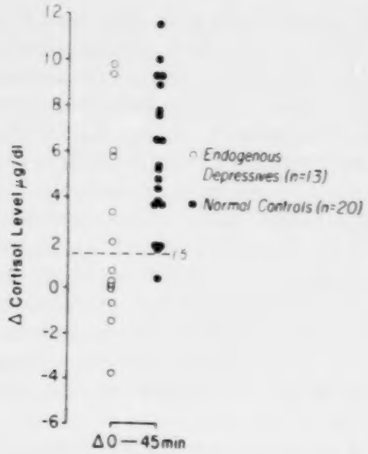

FIGURE 2. The Δ45-minute cortisol response to 75 mg i.m. DMI in 13 endogenous depressives and 20 normal controls as a discriminator between groups.

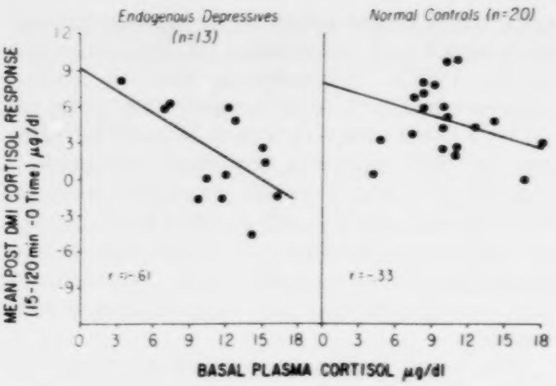

FIGURE 3. Mean post-DMI cortisol response vs. basal plasma cortisol in 13 endogenous depressives and 20 normal controls.

potential covariates: 1) basal cortisol just prior to i.m. DMI; 2) age; and 3) sex. Basal plasma cortisol just prior to i.m. DMI and sex were significant covariates in contrast to age, but only basal cortisol accounted for a sizable portion of the variance (30.9 percent). Nonetheless, the group difference (depressives versus normal controls) still remained highly significant after covarying out any of these factors (*see* Table 1).

Since basal cortisol was the most significant covariate examined, it was further evaluated and plotted against mean post-DMI cortisol in both endogenous depressives and normal controls (*see* Figure 3). As can be seen, baseline cortisol was negatively correlated to DMI-cortisol response in both depressives and controls. But of particular note is that, as a group, the slope of the response of the depressives was greater than that of the controls ($F = 4.98, p < .01$).

Although an actual placebo study was not conducted to definitively rule out that the DMI cortisol response might be a placebo response, or due to cortisol diurnal rhythmicity, stress of venipuncture, etc., a non-DMI procedure day with assessments of cortisol was available for comparison to several time points of the DMI day for many subjects. This non-DMI day procedure (from which the 1–4 p.m. plasma cortisol test was taken) was an assessment of basal cortisol involving an insertion of a cannula in a forearm vein 0900 to 1000 h with sampling of cortisol every 30 min for a minimum of 7 h (time for DMI was always at 0930 h, 30 min after the cannula insertion. Cortisol levels on the non-DMI day were used only after a 30 min adaptation to a post-cannula insertion). Cortisol

TABLE 1. Mean Post-DMI Cortisol Response (Baseline-Corrected) of Endogenous Depressives vs. Normal Controls and the Effect of Covariates.

	Mean ± SD Basal Cortisol (μg/dl)	Mean ± SD Post-DMI Cortisol (μg/dl)	Basal Plasma Cortisol[1]	Sex[1]	Age[1]
Controls $n = 20$	10.31 ± 3.04	4.68 ± 1.34	4.49	4.61	4.84
Depressives $n = 13$	11.31 ± 3.77	1.86 ± 1.55	2.14	1.91	1.80
F for covariates			4.58[2]	5.58[3]	0.37
F for group before/ after controlling for covariate	0.70	33.09[3]	26.72[3]	33.70[3]	39.91[3]

[1] Mean post-DMI response adjusted for the particular covariate.
[2] $p < 0.02$.
[3] $p < 0.001$.

values from the DMI day were compared to the non-DMI day using correlated *t* tests at each time point for both normals and depressives (Figures 4 and 5). Both normals and depressives had higher cortisol levels on the DMI day vs. non-DMI day at most time points after DMI administration. Thus, the cortisol response to DMI appears not to be due to placebo response, diurnal rhythmicity, stress of venipuncture, etc.; the definitive evaluation—a double blind i.m. DMI vs. i.m. placebo (saline) study—is in progress.

DST, Mean 1–4 p.m. Plasma Cortisol and Their Relationship to DMI-Cortisol Response

The 1 mg DST found 46 percent nonsuppressors in the depressives and 5 percent nonsuppressors in the normals (Fisher Exact Test = .008); the mean 1–4 p.m. plasma cortisol level was 9.48 (SE 0.97) μg/dl for the depressives vs. 7.24 (SE 0.52) μg/dl for the normals ($t = 2.22$, $p < .04$).

The DMI Δ45 cortisol, which best discriminated depressives from normals, was highly correlated to the basal cortisol assessment—the mean 1–4 p.m. plasma cortisol—and to the 1 mg DST in depressives (the DST was compared to continuous variables—DMI Δ45 min cortisol and mean 1–4 p.m. plasma cortisol—by point bi-serial correlations). (*See* Tables 2 and 3.) In contrast, there were no significant correlations of these variables within the normal controls.

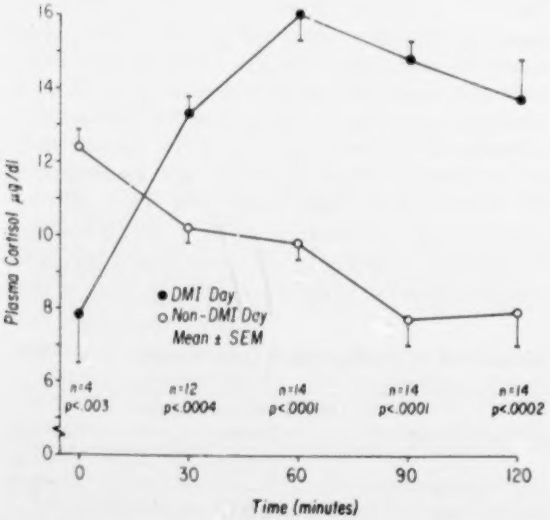

FIGURE 4. Plasma cortisol in a DMI day vs. a non-DMI day in normal controls.

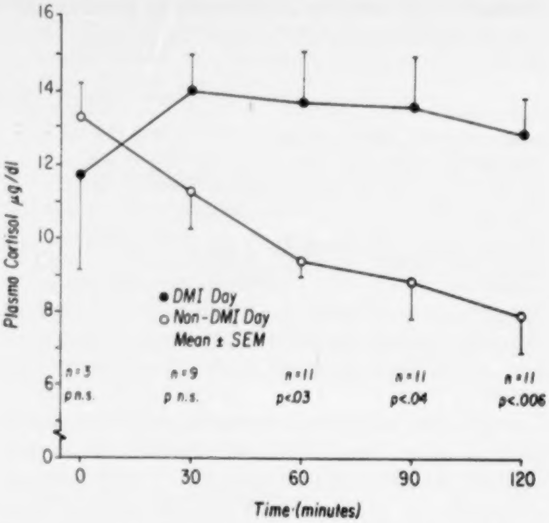

FIGURE 5. Plasma cortisol in a DMI day vs. a non-DMI day in endogenous depressives.

Although mean 1–4 p.m. plasma cortisol and DST significantly correlated to DMI Δ45 min cortisol, these parameters did not explain the group difference (DMI cortisol response) after covarying out DST ($F = 36.20$, $p < .001$) or covarying out mean 1–4 p.m. plasma cortisol ($F = 36.08$, $p < .001$).

Due to the small size of this sample, clinical correlates could not be reliably examined. However, it is useful to point out that, within endogenous depressives, the severity of depression (Hamilton score) was not correlated with mean cortisol post-DMI ($r = .17$, NS).

The DMI cortisol test was well tolerated. There was no significant effect on pulse or blood pressure. Mild dryness of mouth and nausea were occasionally noted in subjects, but side effects were not routinely assessed.

Discussion

The cortisol response to DMI (75 mg i.m.) was significantly decreased in endogenous depressives when compared to normal controls. A lack of a cortisol rise of 1.5 μg/dl above baseline at 45 min (Δ45 min) was the best discriminator between depressives and normals, identifying 7 of 13 depressives and 1

TABLE 2. Correlation Coefficients of Various Cortisol Measures in Normal Controls ($n = 20$).

	DMI Δ45 min	Mean 1-4 p.m. Plasma Cortisol	1 mg DST

*p=NS.

of 20 normals (Fisher Exact Test = .003). This criterion for "inadequate cortisol response" was similar to the one found best in discriminating normals from depressives with i.v. dextroamphetamine by Sachar et al. (1981).

Age, sex, and basal cortisol (plasma cortisol just prior to i.m. DMI) were assessed as potential factors that might effect the cortisol response to DMI. Basal plasma cortisol and sex were significant covariates, but only basal cortisol contributed to a sizable portion of the variance, 30.9 percent. However, after controlling for each of these covariates, the group difference remained significant.

Among the various factors evaluated as to their potential effect on the cortisol response to DMI were other measures of cortisol secretion, namely the 1–4 p.m. plasma cortisol test and 1 mg DST. The DMI cortisol test was found to be negatively correlated to both the 1–4 p.m. plasma cortisol and to the DST in depressives. Interestingly, there were no significant correlations of these variables within the normal controls. It seems that with normal HPA axis functioning these multiple levels of cortisol secretion assessed (basal cortisol, cortisol suppression, and cortisol stimulation) are not correlated. Only when a clear disturbance in the HPA axis occurs (e.g., endogenous depression) do these cortisol parameters become correlated.

Due to the relatively small sample size and the lack of a patient control group or a placebo control in this pilot study, it is difficult to arrive at conclusions about the usefulness of the DMI-cortisol test as a laboratory aid to identify endogenous depressives. But more importantly, this test might serve to identify a biochemically homogeneous subgroup of depressed patients with similar clinical correlates and treatment responsivity. A study currently in progress will address this issue.

The mechanism of action of the cortisol response to DMI brings into question the role of NE in the regulation of cortisol secretion in man. Although animal studies suggest a predominantly inhibitory role of NE on cortisol secretion (Jones, 1978), the data presented in this paper on cortisol response to i.m. DMI—a relatively selective NE uptake inhibitor—suggest a stimulatory role of NE on cortisol secretion. This notion is supported by prior work with i.v. methylamphetamine and dextroamphetamine demonstrating a marked cortisol release in man (Besser et al., 1969; Sachar et al., 1981).

As stated, DMI is considered a relatively selective NE uptake inhibitor. On the other hand, to a lesser extent it is also a serotonin uptake inhibitor (Jarvaid et al., 1979; Randrup & Braestrup, 1977). Thus, it is possible that the blunted cortisol response to DMI in endogenous depression might be due to a serotonin deficit rather than a NE deficit and/or an α-adrenergic insensitivity. Laakman et al. (1985) have addressed this issue and reported that pretreatment of a small number of normal volunteers with methysergide (a serotonin blocker) had no effect on the cortisol

TABLE 3. Correlation Coefficients of Various Cortisol Measures in Endogenous Depressives ($n = 13$).

response to DMI, whereas administration of prazosin, an α 1-adrenergic blocker, resulted in a blunted cortisol response. This finding further supports the notion of a NE deficit and/or α-adrenergic receptor insensitivity being responsible for the blunted cortisol response to DMI in depressives.

A Developmental Perspective on Recurrent Mood Disorders: A Review of Studies in Man

Hagop S. Akiskal, M.D.[1]

Research findings generated during the past decade have generally upheld the multifactional conceptualization of depression deriving from primate (Akiskal & McKinney, 1973) and human studies (Akiskal & McKinney, 1975). Recent findings (reviewed in Akiskal, 1985) also suggest that the predisposition to recurrent mood disorders is developed in childhood and that life events and biological insults in adulthood merely serve as triggering factors. Finally, gender is a nonspecific factor that appears least relevant to the recurrent and bipolar forms of illness (Boyd & Weissman, 1981). In reviewing the clinical literature bearing on the pathogenesis of recurrent mood disorders, I will develop the thesis that the predisposing role of heredity and early life experiences is mediated through personality variables which create the very circumstances that precipitate episodes of mood disorder in adult life.

The Predisposing Role of Heredofamilial Factors

Individuals who have a first-degree biological relative with a mood disorder are at increased risk of developing clinical depression. This risk is highest in the relatives of "schizoaffective" bipolars, followed by those of bipolar I and bipolar II (Gershon et al., 1982). It has been estimated that heredity may contribute 50 percent of the variance in the pathogenesis of *recurrent* mood disorders (Gershon et al., 1971). Although the risk for depression is relatively modest in the relatives of unipolar depressives, many recurrent depressives come from families with bipolar illness. This is best interpreted to mean that some apparently "unipolar" depressions are in fact less penetrant forms of bipolar illness (Akiskal et al., 1983). These depressions typically have early onset, are hypersomnic-retarded in symptom pattern, may exhibit brief switches to hypomania when treated with heterocyclic antidepressants, monoamine oxidase inhibitors, electroconvulsive therapy, or sleep deprivation, and may show preferential responses to lithium carbonate. The heredofamilial risk factor in depression is most dramatically illustrated by comparing the risk in the general population (which approximates the risk for the offspring of unaffected parents) with that of individuals who have one affected parent ("single matings") or both parents affected ("dual matings").

---

[1] Affective Disorders Program, University of Tennessee, Memphis, 66 N. Pauline St., Suite 633, Memphis, TN 38163.

The risk is tripled from the population baseline for single matings and increased at least tenfold for dual matings (Gershon et al., 1982).

Increased familial risk of course is not synonymous with increased genetic risk. Definite evidence for genetic contributions has come principally from adoption studies and monozygotic-dizygotic differences in concordance rates. Adoption studies (e.g., Mendelwicz & Rainer, 1977; Cadoret, 1978; Kety, 1985) have demonstrated increased risk for mood disorders in subjects born to parents with such disorders but raised by normal adoptive parents. However, these findings appear more relevant to recurrent cyclical, rather than pure depressive, disorders (Von Knorring et al., 1983; Cadoret et al., 1985). The wide difference in monozygotic-dizygotic concordance also indicates a strong genetic component (Bertlesen et al., 1977); concordance is the same for monozygotic pairs regardless of whether they are reared together or apart from birth (Price, 1968). The fact that concordance rate is less than 100 percent even in the most genetic (bipolar) forms of mood disorders suggests that nongenetic familial and other environmental factors are of importance in the predisposition to affective episodes. It is also of great theoretical interest that where monozygotic pairs are discordant for affective breakdowns, the unaffected twin often exhibits cyclothymic or dysthymic tendencies (Bertlessen et al., 1977). This suggests that affective illness is not inherited as such, but may be transmitted in the form of temperamental deviations. This was supported in a recent study (Akiskal et al., 1985) that found such deviations in nearly 50 percent of the juvenile offspring of adult bipolars.

The Predisposing Role of Early Home Environment

Although heredity seems to account for a major portion of the variance in the pathogenesis of recurrent mood disorders, nongenetic familial factors appear to modify the actual clinical expression of the disorder. The child reared in a family where one parent suffers from primary mood disorder is exposed to a dual disadvantage: genetic vulnerability to such disorder, as well as separation experiences during childhood through parental illness, suicide, divorce, or more subtle forms of emotional deprivation secondary to conflictual interaction between parents. Such conflict is often aggravated by the fact that the other parent frequently exhibits psychiatric disturbance (assortative mating), ranging from personality and mood disorders to alcoholism (Gershon et al., 1973).

Psychoanalytic theory has long traced adult depressions to early deprivations that preclude adequate mastery of loss situations. According to a specific version of this viewpoint, formulated by Bowlby (1961), the failure to successfully mourn object losses during childhood provides the behavioral sensitization to adult depressions. This notion has found partial support in the high rates of depression in women who have been maternally bereaved in childhood or adolescence (Brown & Harris, 1978). However, the cumulative retrospective evidence has been generally inconclusive regarding the specificity of childhood loss to adult mood disorder (Lloyd, 1980a). Accordingly, in his latest writings, Bowlby (1977) has broadened his formulations to include in the consequences of early loss a large spectrum of adult personality disturbances with mood instability and acting out behavior.

While failing to specifically relate adult depression to childhood object loss, the available research evidence does suggest several interesting links in line with Bowlby's formulations. For instance, we now know from the work of Perris (1966) that unipolar depressives who experienced developmental object loss have an illness onset 10 years earlier than those depressives without such loss. Others (Levi et al., 1966; Hill, 1969) have reported that suicide attempts are more common in depressed subjects who have sustained early separations. Finally, work conducted at the University of Tennessee (Akiskal et al., 1978; Rosenthal et al., 1981) has shown that early losses are associated with the adult occurrence of "unstable" characterologic attributes, such as immaturity, hostile dependency, manipulativeness, impulsiveness, and low threshold for alcohol and drug abuse, rather than overt mood disorders. These findings illustrate how breaks in early object relations could be relevant to certain clinical aspects of depression. While not causing depressive illness, developmental object loss seems to modify the clinical expression of the adult disorder. The characterologic propensity toward hostile dependency may prepare a fertile soil of interpersonal friction that facilitates a depressive onset earlier than that determined by innate genetic factors. Such friction may actually create the life events that trigger the depression. Another possible mechanism whereby early losses can influence the occurrence of adult depression is by creating conditions favorable to the development of character traits associated with what Seligman (1975) refers to as "learned helplessness," or with the self-denigrating depressive mental schemata described by Beck (1967). It is reasonable to assume that situations wherein the individual has failed to master a series of tasks can lead to subsequent helplessness when faced with similar situations. This viewpoint is concordant with classical work at the Wisconsin Primate Laboratory (Harlow, 1975), which demonstrated that coping skills are developed in the context of the contact comfort provided by caring and loving parental objects. Conversely, the loss of this contact comfort often precludes the development of environmental exploration and of coping skills in general. Thus, early separations from parent(s), without adequate substitutes, may prevent the emergence of a sense of mastery of the environment. Such children may become insecure adults who feel unable to face the challenge of new situations. It should be noted that the mere presence of parents, however, does not immunize against the trait of helplessness; developing a sense of mastery requires suitable role models and the opportunity to cope with a series of life events of increasing complexity. Such formulations, while plausible, need verification in prospective designs in clinical populations.

Arguing against the proposed relationship between childhood loss and depression is the fact that history of such loss is not present in two-thirds of adult depressives (Lloyd, 1980a). Furthermore, childhood parental deprivation does not appear to exert *specific* formative influence on depressive illness. It is nevertheless likely that, given specific genetic predisposition to mood disorder, the experience of being raised in an unstable early home environment may contribute to the development of personality disturbances which themselves play a formative role in mood disorder.

The Mediating Role of Temperamental and Characterologic Factors

It is widely believed that affective episodes arise from predisposing personality attributes. This position was most directly articulated by Kretschmer (1936), who believed that "the endogenous psychoses are nothing but accentuation of normal types of temperament." While Kretschmer, as a faithful follower of the Kraepelinian tenets (1921), emphasized constitutionally determined temperamental contributions, much of current theorizing has focused on learned characterologic attributes believed to be a legacy from developmental vicissitudes.

Ideally, the study of personality in a given patient should begin prior to the first onset of affective episodes. Assessing personality during an episode of illness is unsatisfactory because affective states may bias or even mask the patient's personality profile. Even when the affectively ill are examined during a euthymic period, the illness episodes—or the treatments provided for them—significantly alter personality structure. For these reasons, very few studies have succeeded in prospectively assessing the contribution of personality to mood disorders. Despite such thorny methodologic barriers, many interesting findings on the relevance of enduring personality characteristics to mood disorders have been formulated (Akiskal et al., 1983).

Kraepelin (1921) postulated that the various forms of manic-depressive illness often arose from their respective temperamental foundations. For instance, it is fairly well established that certain temperamental disorders—the dysthymic, the hyperthymic, and the cyclothymic—are the precursors of the more serious affective episodes (Akiskal et al., 1977; Akiskal, 1983; Depue et al., 1981). In these temperaments, the genetic potential for affective episodes is considered to be subclinically active at all times and to be easily triggered into clinical illness by environmental characteristics to mood disorders have been formulated (Akiskal et al., 1983).

TABLE 1. Rate of Affective Episodes (Given in Percentages) in Affective Temperaments and Controls During Prospective Observation of 1 to 4 years.*

	(*N*)	Major Depression	Hypomanic/Mania (Spontaneous)	Tricyclic-Hypomania
Cyclothymic	(46)	24	22	35
Subaffective dysthymic	(20)	55	0	33
Nonaffective personality controls	(50)	4	0	0

*Summarized from Akiskal et al. (1977) and Akiskal (1983). Experimental groups significantly higher than controls ($p < .02$).

dysthymic individuals compared with personality controls. It is interesting to note that both temperaments are at highest risk to develop depression; the risk for hypomania is augmented by exposure to tricyclic antidepressants. Recent Italian work (Kukopulos et al., 1980) has shown that tricyclic antidepressants may actually *accelerate* the inherent cyclicity of mood disorders in hyperthymic and cyclothymic individuals. It would therefore appear that certain affective personalities are at high risk of developing depressive states under conditions of environmental challenge; they are also prone to hypomanic and manic states under pharmacologic challenge, as well as under other reactive conditions.

In other words, one mechanism whereby genetic factors may produce episodes is via the instability of the affective temperaments. This viewpoint is strengthened by the recent demonstration of shortened REM latency in individuals with dysthymic and hypomanic temperaments (Akiskal, 1984), very much like the findings in individuals experiencing major full-blown depressions. This sleep neurophysiologic abnormality seems to behave like a trait marker of vulnerability and is not merely a nonspecific stress reaction or a correlate of anxiety (Akiskal et al., 1984). Overall, the sleep findings in affective temperaments suggest that neurophysiologic abnormalities precede full-blown affective episodes.

Temperamental contributions appear to have greater relevance in the recurrent and cyclic forms of mood disorder (Akiskal et al., 1983). In the more purely depressive forms of these disorders, dependency and obsessiveness have long been hypothesized as predisposing factors (Chodoff, 1972); more recent formulations have focused on cognitive-behavioral factors (Lewinsohn, 1974; Kovacs & Beck, 1978). These formulations, which have been developed through retrospective reconstruction of the premorbid characteristics of already depressed subjects, have been based on small clinical populations, have not taken the heterogeneity of mood disorders into consideration, have not used reliable personality measures and, most seriously, have generally tended to confuse state and trait. A recent study (Hirschfeld et al., 1983), which—except for being retrospective—was methodically superior to earlier attempts, reported that introversion, lack of social adroitness, and dependency are the major attributes of recovered depressives. These findings are more consistent with behavioral formulations and suggest the existence of enduring measurable deficits in social skills. Prospective studies are now needed for the more definitive clarification of the characterologic contributions in mood disorders. Despite this limitation, clinical experience suggests mechanisms whereby the postulated characterologic disturbances contribute to major affective episodes. Individuals who are introverted and lack social adroitness do not possess an adequate behavioral repertoire for eliciting rewarding interactions with other people. In particular, they may lack the requisite skills to develop and maintain the supportive relationships that are widely believed to provide a buffer against the depressant impact of aversive life situations (Akiskal, 1985). Passive-dependent individuals can easily exhaust the tolerance of their spouses or lovers and thereby prepare the ground for marital or romantic break-ups. In other words, they may contribute to the very life situations which bring about their depressive breakdowns. Once they become depressed, their dependency needs grow, providing further opportunities for alienating the supportive individuals in their lives. The relationship between personality and mood disorders, however, is not always etiological (Akiskal et al., 1983). Personality may favor the appearance of certain *symptoms*. If and when an affective episode does occur, it may modify the apparent severity of the depressive state and, in many instances, results from recurrently incapacitating episodes of illness (Cassano et al., 1983).

In summary, the individual prone to develop affective episodes is no longer portrayed just in terms of the temperamental traits of cyclothymia, hyperthymia, and dysthymia, but those of related characterologic attributes such as dependency, introversion, and a relative lack of social assertiveness. These traits and attributes, which represent either premorbid personality features or post-episodic complications, appear to be associated with enduring biologic traits, and may serve as a fertile ground for the genesis of major affective episodes.

Precipitating Circumstances

Affective episodes are often temporally related to external and internal circumstances. The preceding discussion suggests that in vulnerable individuals affective disturbance is present subclinically—and that it is activated into overt clinical episodes by environmental challenge. Environmental circumstances may determine the precipitation of the initial episode and, perhaps, the *timing* of subsequent recurrences. These circumstances are extremely varied and include psychosocial, biologic, and seasonal factors.

Although the majority of individuals exposed to losses and other aversive life circumstances do not sink into morbid despair, those predisposed to mood disorders may do so at such times. The lifetime risk for melancholia is about 12 percent (Helgason, 1979), yet no more than 5 percent of those exposed to "exit" type life events decompensate into clinical depression (Paykel, 1976; Clayton, 1979; Lloyd, 1980b). Furthermore, history of previous depressive episodes is a stronger predictor of depression at the face of life stressors than the characteristics of the stressors and their social context (Warheit, 1979). Even individuals predisposed to mood disorders—measured as a function of previous episodes or positive family history—do not develop affective episodes in the face of a major loss; rather, other concurrent or antecedent events seem to mediate the effect of such events (Akiskal, 1985). These include unresolved childhood loss, concurrent life events, impact of life event on life style, symbolic meaning of the life event, inadequate social support, deficient social skills, and personality. Indeed, losses and other aversive events which are common precipitants of depression often result from the affectively unstable personality matrix of the patient (Akiskal, 1984).

The fact that clinically significant depression occurs, on the average, in about 15 percent of the medically ill (Cavanaugh, 1983)—which approximates the lifetime risk for melancholia—is an indication that medical contributions to depression are in the nature of precipitant rather than cause. Reserpine-induced depressions (Goodwin & Bunney, 1971) illustrate this point in that two-thirds of these cases represent "pseudodepressions" secondary to the sedative side effects of the drug, which reverse as medication is discontinued; melancholia persisting in an autonomous fashion despite withdrawal of the offending chemical occurs in the remaining third and is largely limited to those with past personal history or predisposition for depression.

Thus, neither life events nor chemical events appear to be *sufficient* causes for the occurrence of clinical depressions: They seem to exert a depressant influence in the presence of predisposing factors. We know even less about the precipitation of hypomania or mania. The relevance of life events—especially losses—is suggested by Ambelas' study (1979). Obviously such losses can easily result from premorbid cyclothymic or hyperthymic instability in mood (Akiskal, 1984). The best known precipitants of hypomania—and to a lesser extent of mania—are drugs and physiological procedures that increase the central level of catecholamines (Vogel, 1975; Bunney, 1978; Kukopulos et al., 1980). These include the noradrenergic tricyclics, the monoamine-oxidase inhibitors, ephedrine, L-dopa, cocaine, amphetamine-like drugs, REM-deprivation, and total sleep deprivation. These factors, which often represent medically or self-administered treatments—and, in the case of REM-deprivation, a manifestation of the cyclothymic individual's decreased need for sleep—are more consistent in producing a switch from depression to hypomania than from euthymia to hypomania. Thus, the pharmacological switch is largely limited to individuals with a bipolar diathesis—measured as a function of personal or family history of mania (Akiskal et al., 1983). The same applies generally to postpartum affective episodes, whether manic, mixed, or retarded depressive. Another class of precipitating circumstances that has received recent attention is seasonality (Rosenthal et al., 1984), largely relevant to bipolar II disorder.

To summarize, this discussion on precipitating circumstances suggests that the onset of affective episodes is most commonly associated with an interaction between predisposing and triggering factors. Many, though not all, of these triggering factors themselves develop as a result of complex interactions between the environment and the personality of the patient predisposed to mood disorders.

Concluding Remarks

Figure 1 is a diagrammatic representation of the complex interaction between diverse predisposing factors which I have hypothesized lead to the development, during formative years, of biologic and personality attributes that facilitate major affective breakdowns in adult life. Due to space limitations I have deleted a discussion of demographic factors, but as reviewed elsewhere (Akiskal, 1985), gender and age are also associated with certain personality and biologic attributes that favor the circumstances leading to affective dysregulation.

Such a model, to be fully tested in the human, would necessitate detailed prospective observation of children at genetic risk for mood disorders and observed over a period of several decades. Animal models—whether in primates or rodents—provide a convenient approach to examine some of the critical risk factors reviewed in this paper. I would propose that female animals which have been exposed to traumatic separation or aversive stimulation early in life—and which come from genetic strains characterized by severe separation-induced despair responses or repeated failure to escape aversive stimulation—would be at greatest risk for "depressive" behaviors under stressful experimental circumstances. Furthermore, I would predict that exposure to separation or selected chemical stressors in the postpartum period at the early fall or early winter months would be most potent. Finally, I would predict that animals at risk for "depression" would manifest distinct biologic and personality traits *before* the onset of such behavior.

Developmental Theories of Depression in Nonhuman Primates

Gary W. Kraemer, Ph.D.[1]

Introduction

Theories about depression in nonhuman primates center around the "despair" response of infant monkeys to maternal separation. In this phase monkeys typically become lethargic and curl up into a fetal-like posture for long time periods. Historically, the linkage between despair and human depression was made on the basis of two observations. The first is that despairing monkeys "look" depressed. The second is that the monkey response bears a remarkable resemblance to the response of human infants to maternal separations. Some maternally deprived human infants in turn look and act in ways that clinicians have likened to adult depression. Given this parallel, numerous authors have suggested that despair (monkeys) and anaclitic depression (humans), if not homologous, are at least analogous states. If so, despair in monkeys can be viewed as an animal model of depression.

For a host of reasons this approach is controversial. Without even crossing species one can start a debate about the relationship of anaclitic depression to depressions occurring later in life. Rather than feeding a controversy which alternately focuses on similarities and then differences between despair and a variety of conceptions of the nature of depression, this paper will focus on despair as a biological-behavioral phenomenon that is significant and interesting in its own right, and recount some of the things we have learned about it. Then the reader can be the judge.

Fundamental Drive Systems in Primates

Every mammalian species possesses CNS mechanisms that regulate feeding, aggression, fear, sexual behavior, and rearing and protection of offspring.

In some of the social primates these basic mechanisms have merged with, and are dependent upon, a complex social recognition and cohesion system (attachment). The drive to attach is present at birth, but the full development of infant attachment mechanisms requires maternal and then peer interactions. The primary reinforcers are maternal contact comfort (cuddling) and peer play. To put the system in a hierarchical biological context, it resides slightly above nutrition as a survival goal for the infant primate (Harlow & Mears, 1979). Once the infant has become attached to its mother and peers, behavioral mechanisms exist to prevent separation.

The behavioral response to separation is often biphasic. Frantic activity and vocalization ensue upon separation from an attachment object (protest). Later, some infants become inactive. They adopt a self-enclosed fetal-like body posture (huddling) and are silent (despair).

Kaufman (1977) proposed that both the protest and despair phases are positively selected in the feral environment. Protest behaviors increase the probability that the infant will regain contact. Vocalizations are most prominent as a means of attention-getting behavior, but frantic activity and attempts to search for the mother are evident. If the separation is prolonged, the reduced energy expenditure and lack of attention-getting behavior of the despair phase preserve the infant from exhaustion and predation until it is rediscovered by the mother (conservation-withdrawal). This selective framework ensures that monkeys are socialized in the feral environment. If attachment formation is weak, or the attached infant is separated from its mother and these survival strategies fail, the infant does not survive and procreate. Thus, there are no nonsocially reared

monkeys outside of the influence of human husbandry.

While the similarities between the initial responses of infant humans and monkeys to separation from their mothers are profound, in adolescence and adulthood the cross-species parallels are not as clear. This is primarily related to the explosion of human capacity which progressively separates us behaviorally, and perhaps intellectually, from other primates after the initial 5 to 10 percent of expected life span. Monkeys and humans develop attachments to peers, and then to their own offspring. However, humans have diverse cultural differences in social interaction, whereas the rhesus monkey pattern is relatively stereotyped and constant. Humans become attached to a wide array of objects, concepts, and vocations as well as other people. Humans acquire language, a tool used in part to express the depth of their attachments and the devastation of their disruption.

The ubiquitous nature of attachment and the response to attachment disruption makes it so common a phenomenon that many have overlooked the root characteristics of the behavior. Often the point is made clearer by trying to imagine the characteristics of a fellow human who has no response to loss of parents, significant others, children, ideas, goals, morals, or self-esteem, or never develops any of these attachments. Then imagine a society of these individuals, as if such a thing could exist. Therefore, one hypothesis is that this core neurobiological mechanism enables us to maintain a society, a technology, a way of life, and a world view that we are "attached" to. If these attachments are disrupted, or disruption is threatened, then we protest, or we fight. If the loss is sustained, then we despair and adapt. Thus, protest-despair behavior may be a fundamental characteristic of species that can form long-standing attachments. Its associated neurobiological mechanism may have foundations in the primate infant attachment system.

As universal as this genetically based attachment mechanism might be, there are wide individual differences in its expression. Adaptation may be the key to understanding despair. From an ethological standpoint, the despair response is only adaptive if the infant cannot support itself in the environment. Over a prolonged separation it must conserve. In other environments (the laboratory) or at other ages, or in human society, the individual can support itself, or can be adopted and cared for by others. In this context a prolonged despair response is maladaptive because the organism does not function in its environment. It may not react properly to environmental contingencies or sustain itself when there is food and water available. So, why has the response been preserved?

One possibility is that despair is a neurobiological interlude. It may come into play only when all else has failed (behaviorally), and this point would vary with the neurobiological characteristics and previous experience of the individual. Besides conserving energy it could mark a transition in which the organism recasts behavioral strategies to supplant those that have just failed (protest). Under most conditions, neurobiological reorganization and behavioral function which accounts for the loss of the attachment is achieved, and the organism reactivates itself with a behavioral repertoire that is consistent with the prevailing environment. Another consideration relates to pathology. The attachment mechanism is expressed in neurobiological substrate. As with any structural-biochemical system it is possible for something to go wrong. One developmental factor known to be related to predisposition to despair is the nature of the rearing environment.

Persistent Neurobiological Effects of the Early Rearing Environment

If a separation occurs while the mother is the primary attachment object only 10 to 15 percent of human and laboratory housed rhesus infants show life-threatening behavioral despair (Kraemer & McKinney, 1979). In monkeys, significant social separations later in life are usually from peers since maternal attachment is maintained only for the first 9 to 12 months of life. Later separations are rarely life threatening but some juvenile, adolescent, and adult monkeys do become inactive and huddle. Rearing infants with only peer-aged monkeys (maternal deprivation) approximately doubles the proportion of monkeys that become inactive and huddle after separations in adolescence and adulthood

(Kraemer & McKinney, 1979). Some clues as to the neurobiological substrates of the mechanism are surfacing. The increase in vulnerability due to early rearing conditions appears to be associated with changes in brain norepinephrine (NE) systems.

Comparisons have been made between monkeys reared without social-contact comfort (isolation), those reared without mothers (peer-reared), and those reared in socially rich environments with mothers and peers (mother-peer-reared). Long-term effects of these experimentally induced gradations in formation of social attachments will be considered first.

Reductions in locomotor behavior and increases in huddling following administration of catecholamine (CA; collectively referring to both NE and dopamine [DA]) depleting agents occur at different dose levels in differentially reared juvenile (2– to 3-year old) monkeys. Quantity and quality of social stimuli in the rearing environment appear to account for the differences. Alpha-methyl-paratyrosine (AMPT), a tyrosine hydroxylase inhibitor that depletes CNS CA, significantly reduced motor activity in isolated (no social stimuli) monkeys at 200 to 250 mg/kg/day, in separated peer-reared (high-social quantity, low-social quality) monkeys at 12.5 to 25.0 mg/kg/day, and in separated mother-peer reared (high-social quantity and quality) monkeys at doses of 100 mg/kg/day (Kraemer and McKinney, 1979). Thus, maternally deprived peer-reared monkeys are the most sensitive to depressive effects of AMPT, and also most likely to become inactive and huddle following social separation. Isolated monkeys are the least sensitive. They are also not attached to anything. Therefore, it is possible that CA systems in isolated monkeys are not engaged in the regulation of ongoing behavior as they are in socially reared monkeys.

Cerebrospinal fluid (CSF) NE concentration may be affected by rearing environment. Kraemer, Lake, and Suomi (unpublished cross-sectional data) found levels of 379.2 ± 22.7 pg/ml ($N = 11$) in isolation housed monkeys, 675.9 ± 48.3 pg/ml ($N = 11$) in peer-reared monkeys, and 792.4 ± 73.3 pg/ml in mother-peer reared monkeys ($N = 16$) when all monkeys were 2 to 3 years old, and still living in their rearing environments (main effect of rearing condition, $F = 12.2$, $df = 2/35$, $p < .0001$). CSF NE in the isolated monkeys was significantly lower than either of the other groups. CNS NE systems, at least those reflected in CSF, may have reduced output while monkeys are in prolonged isolation.

While these data are limited in scope, the best working hypothesis is that the CNS effects of any degree of social deprivation are reflected, if not mediated, by reductions in NE system activity (reviewed in Kraemer et al., 1985). If the deprivation is prolonged, or occurs during critical developmental periods, then long-standing deficits in the ability of the organism to adapt to changes in the social environment may be produced. In primates, these changes are manifested by effects that resemble denervation supersensitivity and could be due to deprivation induced lesions of the brain NE system (Kraemer, 1985; Kraemer et al., 1984a). Differences in NE system function across individuals may also fit into the hypothesis.

Correlations of CSF NE Levels With Responses to Social Separation

Kraemer et al. (1984b) found that mother-reared monkeys with low CSF NE concentrations (for the group of 8 monkeys examined) were most likely to become inactive and huddle following social separation. This suggested that "low CSF NE" was a risk factor for a depressive response to separation. The reason for individual variation in CSF NE is not known. Clearly, genetic and perinatal factors, as well as the early maternal relationship must be considered. However, the issue is becoming more complicated.

In a recent study (Kraemer, G., Kalin, N., Lake, C.R., McKinney, W.T., unpublished data), CSF was collected from separated monkeys in the morning (9:00) as opposed to the usual afternoon (13:30) collection time. The monkeys that were inactive and huddled the most had the *highest* levels of CSF NE in the morning. The reversal of direction of effect could be because monkeys that cope well with separation maintain a normal diurnal rhythm in CSF NE, whereas the rhythm in despairing monkeys may be blunted or out of phase. A similar situation may prevail in depressed humans. Post et al. (1984) reported that morning CSF NE was increased in depressed patients by comparison to controls.

Mechanisms and Theories

The correlations presented before do not yet relate directly to a brain mechanism or its development. The role, or more likely "roles," of NE in the CNS must be considered. NE systems appear to be involved in at least four levels of adaptation to the environment. They are: 1) Release, reinforcement, and extinction of behavior (Iversen, 1984); 2) Changes in sensory "gating," or tuning of the salience of sensory input in regulating behavioral output (Oades, 1985); 3) Regulation of cyclical rhythms in arousal, i.e., sleep/waking cycle (Kripke, 1984); and 4) Organizational plasticity, or the formation or loss of effective synaptic contact (Kasamatsu et al., 1984). Each mechanism must act within an environmentally adaptive, and yet neurobiologically constrained time frame. Release and reinforcement of behavior occur within seconds, minutes, or hours. Gating changes and cyclical rhythms take minutes, hours, days, or months. Reorganization (a change in the neural structural-biochemical mechanisms underlying all three of the before mentioned processes) takes days to months.

Examination of the behavioral response to social separation suggests that vulnerability factors develop in a long-term time frame (months to years). Precipitating events span days to weeks, while interactions of the response with drug treatment also occur over days to weeks. This suggests three areas in which NE regulated mechanisms could be relevant to the understanding of the substrates of despair. They are:

1) Vulnerability. Deprivation of some classes of early rearing experience can produce vulnerability to both environmental and neurochemical challenges that would otherwise have little effect. While differences in baseline levels of CSF NE bear some relationship to vulnerability to despair, the best hypothesis at this time is that differences found at one time of day or another reflect a regulatory deficit in the NE system. Perhaps the net effect is that individuals who are vulnerable to prolonged despair cannot mobilize the systems (reorganization) which would normally reverse the despair behavior.

It is possible that the neurobiological attachment mechanism, originally selected to maintain social order and survival of primates, has been expanded upon in humans. If so, this system regulates or maintains the sphere of attachments which are common to humans. The expansion of attachment objects or concepts, and potential losses, would leave humans more to despair about. One wonders whether the mechanism is always adequate.

2) Therapeutic lag. Reduced release of NE and/or serotonin has been suggested as both a feature of depression and a state that was counteracted by antidepressant agents. Several well-known effects are incompatible with this "neurotransmitter deficit" hypothesis (reviewed in Stone, 1983). The one most relevant is that antidepressant agents increase neurotransmitter concentration in the synapse within minutes of administration while antidepressant effects take one to three weeks. If NE systems regulate adaptation to the environment through a time-based cascade, then a therapeutic lag is a prerequisite rather than an inconvenience. An example can be given in terms of social separation.

Primates adapt to the mean level of environmental stimulation and avoid social separation. However, the primate social environment is not constant. Brief separations are inevitable. If a prolonged social separation is in progress then efforts must be made to regain contact (protest), and energy must be expended. If this fails, then a number of physiological and behavioral changes must be made to cope with the increased risk to survival (despair and adaptation). On the other hand, if the separation turns out to be transient, then protest and induction of CNS adaptation to the solitary environment may be counterproductive. Therefore, there must be a delay after the perceived separation in order to determine whether adaptive processes must be engaged. The time to fully adapt to the separation environment is the sum of the time required to detect change, the delay to make sure the change is persistent, and the time to make the required physiological and perhaps structural changes in the brain. Completion of the behavioral sequence takes between 3 to 14 days in rhesus monkeys. Changes on a shorter time frame may either be counterproductive in relation to the frequency and duration of transient separations, or exceed the biological limits of the changing mechanisms. Receptor adaptation and then organizational changes may be the focal mechanisms. If antidepressants impact on these basic mechanisms then they also should have a time delay consistent with the function of the mechanisms that they affect.

3) Mechanisms. One mechanism underlying the adaptive capacity of nonhuman primates could be the maintenance of cortical plasticity (Nagatsu et al., 1984) in the sensory-motor and frontal cerebral cortex by NE systems (*see* Levitt et al., 1984). Changes at this level of CNS function probably occur over days to weeks. This time frame is compatible with behavioral responses to social separation and antidepressant treatment. Changes in post-synaptic receptors could signal the induction of these processes. One change in viewpoint from previous theories of depression is that NE systems may not regulate mood (behavioral) states per se, but may regulate the capacity and time necessary to change from one stable mood (behavioral) state to another (*see* Cohen & Campbell, 1984).

Organizational processes are probably intimately linked with biological cycles in arousal, the sleep-wake cycle being primary. Perhaps the simplest mechanistic concept is that you cannot run a railroad and reroute the tracks at the same time. Thus, disrupted sleep cycles could be either a cause or a symptom of deficits in CNS adaptation. Similarly, it is possible that the despair phase reflects a limitation of ongoing behavior so that CNS adaptive processes which alter behavioral programs can be engaged. If the required organizational processes fail, then the behavioral interaction with the environment remains limited.

Conclusion

CNS NE systems appear to be involved in mediating behavioral adaptation to changes in the social environment. Development of NE systems may be promoted by social interactions in the first year of life. These systems may be damaged or fail to develop if the infant is socially isolated, or if it is deprived of a selective class of social stimuli. There are also individual differences that appear to be independent of rearing and could be related to genetic and perinatal factors. One effect of debilitation of these adaptive mechanisms could be the persistent maintenance of behavior patterns that are inappropriate in the prevailing environment. Prolonged despair could be an example.

Multiple Forms of the D_1 Dopamine Receptor: Its Linkage to Adenylate Cyclase and Psychopharmacological Effects

Richard B. Mailman, Ph.D.,[1] David W. Schulz, Ph.D.,[2] Clinton D. Kilts, Ph.D.,[3] Mark H. Lewis, Ph.D.,[4] Hans Rollema, Ph.D.,[5] and Steven Wyrick, Ph.D.[6]

Introduction

It is accepted that antipsychotic drugs act principally by blocking postsynaptic dopamine receptors. The most accepted hypothesis divides dopamine receptors into two classes on the basis of specific biochemical characteristics—the D_1 class is linked to stimulation of cyclic adenosine monophosphate (cAMP) synthesis by dopamine, whereas the D_2 class is not (Kebabian & Calne, 1979). It was the D_2 class that had been believed to mediate both antipsychotic effects in man and various antidopaminergic behavioral effects in laboratory animals (cf. Calne, 1980; Creese et al., 1983). While providing an interesting unifying hypothesis, this scheme (or one of its various permutations) often was not reconcilable with available psychopharmacological data (e.g., Niedzwiecki et al., 1984; Lewis et al., 1983; Mailman et al., 1981; Schulz et al., 1984a). Moreover, it provided no biochemical mechanisms (other than effects of cAMP synthesis) that could be linked with functional changes.

For these reasons, the general hypothesis we have used during the last few years is that there is a functionally relevant microheterogeneity of dopamine receptors throughout the brain, and although the ligand recognition characteristics of these receptors may be different (e.g., catechols act on both sites; ergots only the latter), the functional consequences of receptor occupation also reflect the cellular location of the receptors. Two working hypotheses resulting from these

ideas were: 1) that D_1 dopamine receptors, as well as D_2, can mediate profound antidopaminergic behavioral effects; and 2) that the D_1-dopamine receptors are not always linked to stimulation of cAMP synthesis.

Psychopharmacological Effects of D_1 Dopamine Antagonists

An important tool for investigating the psychopharmacology of dopamine receptors has been SCH23390. The initial report showing biochemical selectivity of this compound suggested that it caused few of the psychopharmacological or neurochemical effects associated with D_2 receptor blockade (Iorio et al., 1981; 1984), consistent with its designation as a selective D_1 antagonist (Cross et al., 1983; Hyttel, 1983). However, our early studies surprisingly showed that SCH23390, administered to rats parenterally, rather than orally, was as potent as haloperidol at antagonizing behaviors induced by direct or indirect acting dopamine agonists (Mailman et al., 1984a; 1984b). These psychopharmacological effects of SCH23390 have since been confirmed and expanded by numerous groups (e.g., Christensen et al., 1984). Of particular interest is the fact that SCH23390 was several-fold more potent than fluphenazine when given directly into the brain. These latter data indicate that it is probably not a metabolite of SCH23390 that is responsible for its behavioral effects, nor does it have antidopaminergic potency simply because it inhibits the entry of amphetamine or other dopamine agonists into the brain.

Unusual Aspects of the Pharmacology of SCH23390

Using a High Performance Liquid Chromatography-based analytical method (Kilts et al., 1985), it was found that the plasma half-life of SCH23390 is less than 1 hour, and it appears that the compound has an extremely large volume of distribution after oral administration. Of greater interest, however, is the fact that after i.p. administration, the brain concentrations of SCH23390 are still near maximal at 2 hours, although the plasma concentrations are almost undetectable at this time. Thus, the persistent biochemical and behavioral effects of SCH23390 seen after clearance of the drug from the circulation (Schulz et al., 1985a) may reflect the prolonged presence of this drug at critical recognition sites in the brain, a pattern that is quite different from classical antipsychotic drugs.

Another interesting contrast between SCH23390 and other dopamine receptor blockers is its relative lack of effect on dopamine synthesis and release, and the firing of dopaminergic neurons. In our early psychopharmacological studies, haloperidol (0.3 mg/kg) caused increases of 150–300 percent in 3, 4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) concentrations (a measure of dopamine turnover), whereas no dose of SCH23390 increased DOPAC or HVA in any region by more than 25 percent. In microdissected dopamine terminal fields throughout brain there was also no evidence of changes in dopamine synthesis and release as estimated by changes in either metabolite concentrations, or rate of dopamine utilization after synthesis inhibition. Conversely, other antipsychotic drugs showed dramatic (and regionally specific) effects using both techniques. Consistent with these data, SCH23390 also failed to affect neurotransmitter release in the electrically stimulated, perfused rabbit striatal slice. It neither reversed apomorphine- or nomifensine-induced inhibition of dopamine release at concentrations of 1 μM. Similarly, in identified dopamine cells in the substantia nigra, behaviorally potent doses of SCH23390 were unable to reverse the apomorphine-induced inhibition of firing (Napier et al., 1986).

Effects of SCH23390 on In Vivo Receptor Binding

Feenstra and coworkers (Feenstra et al., 1983a; 1983b; 1983c; Rollema et al., 1986) have demonstrated that there is saturable accumulation of the dopamine agonist dipropyl-(±)-2-amino-5,6-dihydroxy-1,2,3,4-tetrahydronaphthalene (diPrADTN) in striatal membranes, and that the effective dose in 50 percent of subjects (ED_{50}) for this accumulation is similar to the ED_{50} for the induction of stereotyped behavior (Feenstra et al., 1983a; 1983c; Rollema et al., 1986). Moreover, various antipsychotic drugs were found to displace this specific accumulation of dipropyl-5,6-ADTN at the same doses that they inhibited the behavioral effects of the agonist (Feenstra et al., 1983a; 1983c; Rollema et al., 1986). Conversely, the neurochemical changes caused by diPrADTN treatment (i.e., decreases in DOPAC and HVA concentrations) have a lower ED_{50} than for effects on specific binding or induction of stereotypy. A series of experiments was performed to assess the effects of SCH23390 on the *in vivo* binding of diPrADTN, and although SCH23390 blocked the behavioral effects of diPrADTN, it did not displace the specific binding of diPrADTN in striatum (Figure 1). Conversely, in the same experiments *cis*-flupenthixol and haloperidol, but not *trans*-flupenthixol, did cause the expected displacement of diPrADTN. Two hypotheses may explain these data: only a small portion of the high affinity diPrADTN binding sites is directly related to behavioral changes, or, alternately, that SCH23390 can cause blockade of agonist-induced behavioral effects by interacting with sites different from those required to initiate these behaviors.

Biochemical Pharmacology of SCH23390

One hypothesis that was evaluated early in our studies was whether SCH23390 acted via generalized effects on cAMP systems. While it was found that SCH23390 completely antagonized dopamine-stimulated adenylate cyclase in the dorsomedial frontal cortex, in this region it inhibited only that portion of norepinephrine-stimulated adenylate cyclase which could be attributed to stimulation of dopamine receptors. In striatum, adenosine-receptor mediated stimulation of adenylate cyclase was not reversed by SCH23390, nor did SCH23390 have effects in NG108-15 neuroblastoma cells at opiate, muscarinic, or alpha$_2$-adrenergic receptors mediating the regulation of cAMP synthesis. Finally, SCH23390 did not inhibit basal adenylate cyclase activity in any system tested, nor did it inhibit the increase in cAMP synthesis induced by forskolin. Thus, it seems clear that SCH23390 does not act by interfering with the catalytic unit, the nucleotide binding protein, or the processes by which non-dopamine stimulatory ligands couple with adenylate cyclase. Finally, it was also determined that SCH23390 does not affect phosphodiesterase activity.

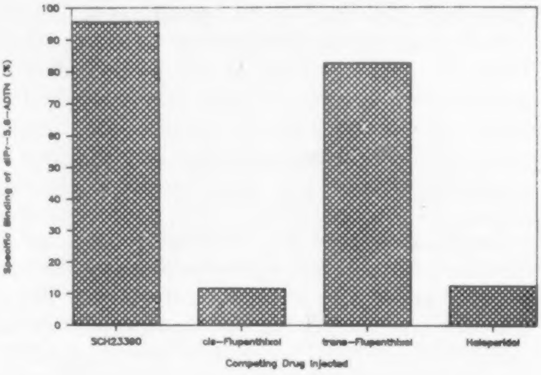

FIGURE 1. The effects of SCH23390 on the *in vivo* binding of dipropyl-5,6-ADTN. Values shown are the specific binding of dipropyl-5,6-ADTN defined per Feenstra et al., 1983. Doses of competing drugs used were: SCH23390—1.07 mg/kg; *cis*- or *trans*-flupenthixol—5 mg/kg; and haloperidol —1 mg/kg.

To provide additional evidence for the hypothesis that SCH23390 acted principally via dopamine receptors, [9-^{3}H]-SCH23390 was synthesized (Wyrick and Mailman, 1985), and its binding characterized (Schulz et al., 1984b; 1985b). The regional distribution of high-affinity, specific [^{3}H]-SCH23390 binding sites in the rat brain correlated well with levels of endogenous dopamine (Figure 2).

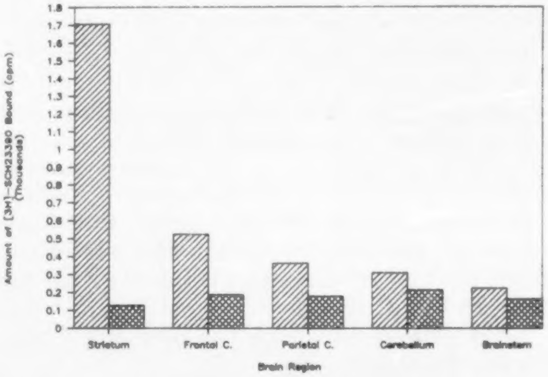

FIGURE 2. The regional distribution of binding of [9-^{3}H]-SCH23390 (3 nM) in several areas of the rat brain. For each region, the left hand bars are total binding, whereas the right hand bar is binding in the presence of 1 µM SCH23390.

Receptor densities were greatest in corpus striatum, nucleus accumbens, and olfactory tubercle; intermediate levels were found in several limbic and cortical areas; while few sites were detectable in cerebellum, brainstem, and olfactory bulb. Specific binding in caudate-putamen was found to be both temperature- and pH-dependent, and appeared to be of a single class of binding sites, or of classes with similar characteristics. Both dopamine and *cis*-flupenthixol altered the slope, but not the intercept, of lines generated by Scatchard analysis. Moreover, the pharmacology of the interactions of [H]-SCH23390 with binding sites in striatal homogenates seemed consistent with an action as a dopamine receptor antagonist (*see* Schulz et al., 1984b; 1985b).

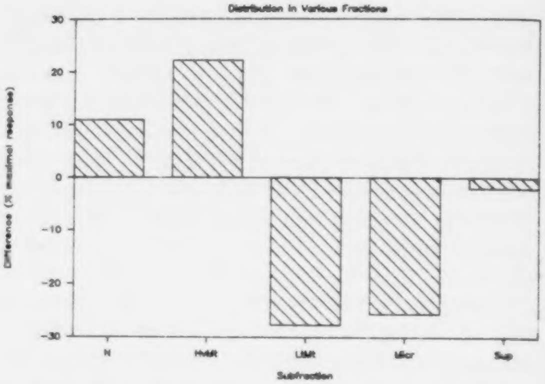

FIGURE 3. Difference in [^{3}H]-SCH23390 binding sites versus dopamine-sensitive adenylate cyclase in cellular subfractions of rat striatum. Values are expressed as percent of maximal concentration of each biochemical parameter. Positive values indicate that relative concentration of dopamine stimulated-adenylate cyclase in that subfraction was higher than the amount of [^{3}H]-SCH23390 binding.

Multiple D_1 Receptors: Differential Distribution of Dopamine–Sensitive Adenylate Cyclase and [^{3}H]-SCH23390 Binding Sites

A critical issue in investigating the biochemical pharmacology of D_1 dopamine receptors is whether all such sites are linked to dopamine-mediated cAMP synthesis (Kebabian and Calne, 1979), or if there are sites with similar recognition characteristics linked to other biochemical events. This latter hypothesis was tested in two ways.

In one series of studies, the rat corpus striatum was subfractionated using differential centrifugation. As can be seen in Figure 3, these studies demonstrated that [^{3}H]-SCH23390 binding sites and dopamine-sensitive adenylate cyclase had significantly different distributions among the various cellular fractions. The [^{3}H]-SCH23390 binding sites tended to be concentrated in lighter cellular fractions relative to dopamine-sensitive adenylate cyclase (Schulz et al., 1985c). These data suggest either that there are spare D_1 dopamine receptors which are localized in cellular structures different than dopamine-sensitive adenylate cyclase, or that the D_1 class of dopamine receptors are actually several populations.

Consistent with the second of these hypotheses, we have found that although basal cAMP synthesis rates are very high in tissue homogenates of rat amygdala, there is no detectable stimulation by addition of dopamine. Dopamine did cause a pronounced dose-dependent increase in cAMP synthesis in tissue from the same animals taken from areas adjacent to the amygdala (i.e., the striatum). SCH23390 alone did not increase or decrease cAMP synthesis in the amygdala (Mailman et al., 1985). Despite the absence of dopamine-stimulated adenylate cyclase in the amygdala, there are significant concentrations of high affinity [^{3}H]-SCH23390 recognition sites in this brain region. Together, these findings suggest that all D_1 receptors (as least as defined by [^{3}H]-SCH23390 binding) are not linked to cAMP synthesis.

Summary

The data summarized above indicate that the psychopharmacological actions of SCH23390 are almost certainly due to interaction of this drug with binding sites that fit the pharmacological characteristics expected of dopamine receptors. Moreover, generalized effects on cAMP systems do not seem to be involved, nor is there evidence that classical neurotransmitters other than dopamine are directly affected by this drug at doses which are psychopharmacologically active. The studies with dipropyl-5,6-ADTN also suggest that functionally important interactions may exist between the D_1 and D_2 classes of receptors, and that the former class may modulate the actions of the latter.

In this regard, it is of particular importance to resolve whether the D_1 dopamine receptor is a single class of sites that always acts via cAMP-dependent mechanisms. Our data suggest there are biochemically distinct sites with similar ligand recognition characteristics that are not linked to cAMP synthesis. A plausible hypothesis may be that much of the psychopharmacological potency of the D_1 class of receptors may be mediated by biochemical mechanisms unrelated to cAMP synthesis. A model consistent with our data is shown in Figure 4.

These biochemical data provide clear evidence that the basis for classification of dopamine receptors into the D_1 and D_2 categories must now be redefined. The impact on both basic and clinical neuropharmacology of verifying such a concept seems obvious. Clinically, it may be possible to design new, truly "atypical," antipsychotic drugs with much greater selectivity, or more selective agonists for uses in neurological disorders such as parkinsonism. Similarly, these data should help in developing new insights into the neurobiology of dopamine-receptive neurons.

Structural Analogs of SCH 23390 as Discriminators of Dopamine Receptor Subtypes: Behavioral Interactions Between D-1 and D-2 Agonists and Antagonists[1]

Kathy M. O'Boyle, Ph.D.,[2] Anthony G. Molloy, M.Sc.,[2] Marcellina Mashurano,[2] and John L. Waddington, Ph.D.[2]

Recent studies with the first agents to show the characteristics of a selective D-1 dopamine (DA) receptor antagonist, the 7-halogenated benzazepines SCH 23390 (Iorio et al., 1983; Hyttel, 1983; O'Boyle & Waddington, 1984a; Mailman et al., 1984) and SK&F 83566 (O'Boyle & Waddington, 1984b), have revealed a number of unexpected properties. These include the blockade of a variety of responses previously attributed to D-2 receptor function. For example, in the intact rodent, stereotyped behavior induced by the non-selective D-2 agonist apomorphine and by the selective D-2 agonist RU 24213 are potently blocked by SCH 23390 and SK&F 83566. One interpretation of such findings is that D-1 and D-2 receptor systems may be functionally linked and that D-1 dopaminergic function may be necessary to "enable" the expression of responses initiated by D-2 receptor stimulation in the whole animal (Pugh et al., 1985: Molloy & Waddington, 1985b).

The prominent behavioral effects of SCH 23390 and SK&F 83566, apparently resulting from blockade of tonic D-1 dopaminergic activity, might seem at variance with the failure of the selective D-1 agonist SK&F 38393 to induce typical dopaminergic responses such as stereotypy. However, we have noted it to induce more subtle forms of behavior; thus, SK&F 38393 induces, under particular experimental conditions, episodes of non-stereotyped grooming interpolated between episodes of non-stereotyped sniffing, with some rearing and locomotion (*see* Molloy & Waddington, 1984 and 1985a, for descriptions of behaviors).

Presented here is a preliminary account of further efforts to characterize 1) additional selective benzazepine agents potentially able to discriminate between D-1 and D-2 receptors, and 2) behavioral responses to a D-1 agonist using the *R*- and *S*-enantiomers of SK&F 38393 and SK&F 83566. Additionally, we briefly describe some of our initial studies on the concurrent administration of SK&F 38393 and RU 24213.

Studies With Benzazepine Derivatives

SCH 23390 and SK&F 38393 are 8-hydroxy-1-phenyl-2,3,4,5-tetrahydro-1H-3-benzazepines, differing only in their 7- and 3-substituents which respectively confer full antagonist and partial agonist activities at D-1 receptors. We have investigated further a series of benzazepine analogs differing only in substituents at these apparently critical 3- and 7- positions (O'Boyle & Waddington, 1985a; *see* Table 1). These drugs and reference dopaminergic compounds were compared for their activity to displace the binding of ^{3}H-SCH 23390 from D-1 receptors in human post mortem putamen (0.3 to 0.8 nM ^{3}H-SCH 23390, specific binding defined by 100 nM piflutixol; O'Boyle & Waddington, 1985b). Results were contrasted with our previous measures of their affinities for rat striatal D-1 and D-2 receptors, assessed using ^{3}H-piflutixol and ^{3}H-spiperone respectively (O'Boyle & Waddington, 1985a).

Our behavioral procedures have been presented in detail elsewhere (Molloy & Waddington, 1984) and involve assessing responses to SK&F 38393 after a period of prolonged habituation using a combined rapid

TABLE 1. Displacement of ^{3}H-SCH 23390 in Comparison With ^{3}H-Piflutixol and ^{3}H-Spiperone.

Displacing Agent	K_i (nM)		
	^{3}H-SCH 23390	^{3}H-PIF	^{3}H-SPIP
Flupenthixol	12	0.8	1.0
Fluphenazine	49	19	1.0
Domperidone	2,700	>5,000	0.3
Sulpiride	>50,000	>50,000	109
Dopamine	1,300	23,300	778
SK&F 77174 (7-H-3-H)	898	590	22,900
SK&F 38393 (7-OH-3-H)	735	1,390	12,600
SK&F 83692 (7-H-3-CH_3)	538	165	1,300
SK&F 75670 (7-OH-3-CH_3)	132	1,400	30,600
SK&F 85257 (7-CH_3-3-H)	169	75	7,300
SCH 23390 (R)(7-Cl-3-CH_3)	1.3	0.7	1,080
SK&F 83566 (R)(7-Br-3-CH_3)	2.7	1.4	1,200
SK&F 83566 (S)(7-Br-3-CH_3)	1,470	425	5,100

Data are means of 2 to 5 separate estimations.

time-sampling behavioral checklist technique and conventional stereotypy rating scale. Rats were challenged with *R*- or *S*-SK&F 38393; in characterization studies, *R*-SK&F 38393 was given after 30 min pretreatments with antagonists. Behavioral counts for grooming (Gr), a characteristically intense grooming response (Gr_i), and sniffing (Sn) were obtained by summing the number of observation windows in which these behaviors were recorded, over 20 to 40 min after challenge for grooming responses and over 30 to 60 min after challenge for sniffing. In combination studies, rats were challenged with SK&F 38393, with RU 24213, or with RU 24213 given 10 min after pretreatment with SK&F 38393. The peak score on the stereotypy scale allocated to each animal and the qualitative features of that peak response were analyzed.

Receptor Selectivities of Some Further Benzazepine Derivatives

In human putamen, the binding of ^{3}H-SCH 23390 shows characteristics (O'Boyle & Waddington, 1985b) similar to those previously described for rat striatum (Billard et al., 1984). The D-1 profile for displacement of ^{3}H-SCH 23390 binding over the range of compounds compared in Table 1 was very similar to that for ^{3}H-piflutixol ($r = 0.84$, $p < 0.005$) but distinct from that for ^{3}H-spiperone ($r = 0.41$, NS). Relationships between structure and affinity for D-1 receptors vs. D-2 receptors within this further benzazepine series have recently been discussed in detail in relation to displacement of ^{3}H-piflutixol vs. ^{3}H-spiperone (O'Boyle & Waddington, 1985a). The actions of these analogs to displace ^{3}H-SCH 23390 were similar, with the exception that the 7-OH-3-CH_3 compound (SK&F 75670) appeared to be a somewhat less potent displacer of ^{3}H-piflutixol. Generally, 7-substituents, particularly halogens, were critical determinants of affinity for D-1 but not D-2 receptors, over a range of some three orders of magnitude. Conversely, 3-substituents had somewhat less marked effects, and their influence extended to affinity for D-2 as well as D-1 receptors. In human brain, ^{3}H-SCH 23390 was potently and stereoselectively displaced by *R*- but not by *S*-SK&F 83566. Similarly, we have previously reported that in rat striatum the D-1 affinity of SK&F 38393 and of SK&F 83566 resides stereoselectively in their *R*- but not their *S*-configuration, while weak residual affinity for the D-2 receptor shows negligible enantioselectivity (O'Boyle & Waddington, 1984a,b).

Responses to the Enantiomers of SK&F 38393 and SK&F 83566

The comparative effects of 20 mg/kg of the *R*- and *S*- enantiomers of SK&F 38393, in terms of the induction of behaviors, are shown in Table 2. There appeared to be little induction of Sn by *S*-SK&F 38393, with this effect residing in the *R*-enantiomer. While Gr was also induced by *R*-SK&F 38393, there

	0.2	1.2 ± 0.4*	1.8 ± 0.6*	0.6 ± 0.6*
+ MET	1.0	12.6 ± 0.6	4.3 ± 0.4	0.8 ± 0.4*
	5.0	8.1 ± 1.1	2.9 ± 0.5	0.5 ± 0.3*

Means ± SEM, $n = 4$ to 38; $^{\wedge}p < 0.01$ vs. vehicle; $^{*}p < 0.05$ vs. *R*-SK&F 38393; Mann-Whitney 'U' test.

was some activity in its *S*-antipode; this involved the induction of grooming of the face with forepaws. The induction of Gr$_l$ showed complete enantioselectivity, being induced by *R*- but not by *S*-SK&F 38393.

As shown in Table 2, all three of these behaviors induced by 20 mg/kg *R*-SK&F 38393 were blocked by as little as 100 µg/kg SCH 23390. No such blockade was associated with 200 µg/kg *S*-SK&F 83566, and Gr and Gr$_l$ responses were in fact increased by this pretreatment. However, all three behaviors were dose-dependently blocked by 40–200 µg/kg *R*-SK&F 83566 with complete enantioselectivity. The selective D-2 antagonist metoclopramide (1.0 to 5.0 mg/kg) tended to reduce behavioral counts for Sn and Gr, and antagonized the induction of Gr$_l$.

Responses to SK&F 38393 and RU 24213 Alone and in Combination

When given alone, 15 mg/kg SK&F 38393 failed to induce stereotyped behavior (mean peak scores <2) while 2.5 mg/kg RU 24213 was a threshold dose for the induction of bursts of stereotyped sniffing and locomotion (Table 3). A 10-min pretreatment with 3 to 15 mg/kg SK&F 38393 dose-dependently potentiated responses to this dose of RU 24213. The combination of 15 mg/kg SK&F 38393 and 2.5 mg/kg RU 24213 produced stereotypy scores which significantly exceeded those associated with either drug given alone. In this combination group, 50 percent of animals showed the compulsive stereotypies of fixated sniffing, with or without licking, while these behaviors were not evident in any of the single treatment groups.

The Nature of Behavioral Responses to SK&F 38393

There was significant and substantial separation between the enantiomers of SK&F 38393 for the induction of Sn and Gr$_l$; in the latter case, behavioral activity showed complete enantioselectivity for *R*- but not *S*-SK&F 38393. This parallels the D-1 agonist activity of the enantiomers, which also resides stereoselectively in the *R*- configuration. This is strong evidence that the present behavioral effects have their basis in D-1 receptor stimulation. The activity of *S*-SK&F 38393 to induce some episodes of Gr need not contradict this analysis, as the compound so designated is not enantiomerically pure and contains a modest proportion of its *R*-antipode as contaminant (Kaiser et al., 1982); this would account for some behavioral activity in the *S*-

TABLE 3. Behavioral Responses to SK&F 38393 and RU 24213 Alone and in Combination.

Drug(s)	mg/kg	Stereotypy Score	Compulsive Stereotypy
Vehicle		0.9 ± 0.2	0/8
SK&F 38393	15.0	1.8 ± 0.2	0/8
RU 24213	2.5	2.4 ± 0.2	0/8
RU 2.5 + SK&F	3.0	2.9 ± 0.4	0/8
RU 2.5 + SK&F	15.0	3.4 ± 0.4*	4/8*

Means ± SEM. $^{*}p < 0.05$ vs. RU or SK&F alone; Mann-Whitney 'U' test or Fisher probability test.

sample at such high doses, in terms of low threshold Gr (and occasional Sn) responses, but its inactivity to induce the high threshold Gr$_i$ response.

The ability of as little as 100 µg/kg SCH 23390 to block all behaviors induced by *R*-SK&F 38393 further suggests a primary role for D-1 receptor stimulation in the genesis of these responses. Their antagonism by SK&F 83566 showed complete stereoselectivity for the *R*- but not the *S*- enantiomer, in which D-1 antagonist activity resides. Thus, a primary role for D-1 receptors in the induction of these behaviors is again indicated.

Moderate doses of the selective D-2 antagonist metoclopramide tended to lower counts for Sn and Gr induced by *R*-SK&F 38393 and antagonized Gr$_i$. We have previously noted that metoclopramide does not influence the general prevalence of *R*-SK&F 38393-induced grooming (Molloy & Waddington, 1984); metoclopramide may have some activity to attenuate the overall severity of grooming, or else individual forms of grooming response may be pharmacologically distinct from each other or from other behaviors. Both prevalence and counts for rearing and locomotion induced by *R*-SK&F 38393 are antagonized by metoclopramide as well as by SCH 23390 (Molloy & Waddington, 1985a; Molloy et al., 1986). Such data might also be explained if D-1 and D-2 receptor mechanisms do not invariably constitute functionally independent processes, such that drug effects on D-2 receptor activity may modulate the expression of certain behaviors induced by D-1 receptor stimulation.

D-1: D-2 Receptor Systems and the Regulation of Behavior

Selective D-1 agonists can, under particular experimental conditions, induce episodes of non-stereotyped behaviors, such as prominent grooming, which are sensitive to blockade by selective D-1 antagonists. Stereochemical relationships, revealed using the enantiomers of SK&F 38393 and SK&F 83566, are particularly powerful evidence for a primary role of D-1 receptor stimulation in the initiation of these responses. However, these are clearly not simple processes. The selective D-2 antagonist metoclopramide is able to influence responsiveness to SK&F 38393 (see above) and the selective D-1 antagonists SCH 23390 and SK&F 83566 are able to influence responsiveness to RU 24213, in the latter instance with complete enantioselectivity (Pugh et al., 1985; Molloy & Waddington, 1985b). One interpretation of these data is that there is only one brain DA receptor, such that behavioral responses do not show consistent selectivity for receptor antagonists; this would question the functional relevance of the D-1:D-2 subdivision that is usually made on in vitro considerations (Leff & Creese, 1983). However, selective D-1 and D-2 agonists do induce different forms of behavioral response, even though they are not doubly-dissociable in terms of selective D-1 and D-2 antagonists. Interestingly, the mixed DA agonist apomorphine induces grooming behavior only in animals pre-treated with metoclopramide, perhaps by antagonizing prepotent D-2 activity and unmasking the D-1 component (Molloy & Waddington, 1985a). The status of SCH 23390 and RU 24213 as selective agents, the possible generation of nonselective active metabolites, and the influence of possible nondopaminergic actions have been discussed previously (Pugh et al., 1985) and cannot easily account for such results. In saturation studies of ^{3}H-piflutixol and ^{3}H-spiperone binding, SCH 23390 increases the K_D for the former at sub-nM concentrations, but increases the K_D for the latter only in the µM range, while B_{max} values did not appear to change; thus SCH 23390 shows the properties of a potent, competitive D-1 antagonist with weak residual competitive D-2 antagonist activity. Also, SCH 23390, at a concentration 5-fold greater than was necessary to so influence ^{3}H-piflutixol binding, fails to influence the potent displacement of ^{3}H-spiperone by RU 24213 (O'Boyle et al., 1986). Thus SCH 23390 does not appear to influence D-2 receptor characteristics at the level of the protein recognition site.

If D-1 antagonists block D-2 agonist-induced responses, a corollary would be that D-1 agonists might alter the form of responses to D-2 agents in the direction of fixated stereotypies. We have found it difficult to induce compulsive, fixated stereotyped behavior even with high doses of the selective D-2 agonist RU 24213 (Pugh et al., 1985), although these are a typical response to the mixed D-1/D-2 agonist apomorphine. Perhaps these distinctions reflect the absence and presence of D-1 agonist activity. In preliminary studies, we have found that a threshold dose of RU 24213 for the induction of stereotyped behavior induces a greater compulsive stereotypy response when immediately preceded by SK&F 38393. Thus both decreasing *and* increasing D-1 dopaminergic tone appears able to modulate the intensity of expression of D-2 receptor-stimulated behaviors.

Putative mechanisms for how D-1 agonists and antagonists might influence D-2 agonist responses, such as those discussed above, are conjectural and supported only by indirect data; even less is known about how D-2 antagonists might influence behaviors initiated by D-1 receptor stimulation. Perhaps the situation is somewhat analogous conceptually to the effects of adrenergic antagonists on cardiovascular indices; both α- and β-receptor blockers can induce a reduction in blood pressure, but these effects are mediated via distinct receptor subtypes through which initially distinct mechanisms ultimately influence the same physiological process.

The introduction of these new specific and selective D-1 agonist and antagonist drugs, especially as enantiomeric pairs, has prompted new interest in D-1 receptor function. The notion of concerted D-1: D-2 interplay in the regulation of dopaminergic behaviors (Molloy & Waddington, 1984; Pugh et al., 1985) clearly requires mechanistic support at the neuronal level. Perhaps distinct D-1 and D-2 receptor systems can in some instances each exert an influence over what is ultimately the same efferent pathway, as in a neuronal logic gate. A note of caution is required as these concepts have evolved from studies with only a single class of selective D-1 antagonist.

However, any mechanism must be able to account for the ability of each receptor subtype to select a particular mode of expression of the same behavior, e.g., nonstereotyped vs. stereotyped sniffing, and also to initiate different behaviors such as grooming. Additionally, in animals in whom tonic DAergic function has been removed by 6-hydroxydopamine or reserpine/α-methyl-*p*-tyrosine pretreatment, and in whom adaptive receptor changes are likely, D-1 and D-2 receptors can then be double-dissociated in terms of responses to D-1 or D-2 agonists and their differential responses to selective antagonists (Arnt, 1985; Breese & Mueller, 1985). Thus the extent of tonic DAergic activity appears to be a crucial determinant of the behavioral profile of selective D-1 and D-2 agonists and antagonists.

Acknowledgment

We are most grateful for gifts of experimental drugs from Roussel, Schering, and Smith Kline & French.

Biochemical and Behavioral Studies of D_1 Dopamine Receptors Utilizing SCH23390[1]

Ellen J. Hess, B.A.,[2] and Ian Creese, B.A., M.A., Ph.D.[2]

Previous research has demonstrated the existence of two distinct dopamine receptor subtypes (Creese et al., 1983; Kebabian & Calne, 1979), possessing unique pharmacologic and biochemical properties. D_1 dopamine receptors stimulate adenylate cyclase activity (Hyttel, 1978), while D_2 dopamine receptors inhibit this enzyme (Battaglia et al., 1985; Onali et al., 1984; Stoof & Kebabian, 1981), and have been implicated as the site mediating the antipsychotic and antidopaminergic activity of neuroleptics (Creese et al., 1976; Seeman et al., 1976).

The functional role of D_1 receptors has not been clearly defined due to the lack of *selective*, high-affinity D_1 receptor ligands. To date, the thioxanthenes, [^{3}H]cis-flupentixol and [^{3}H]cis-piflutixol, have been the only suitable radioligands available for labeling D_1 receptors. Since these ligands exhibit similar affinities for both D_1 and D_2 receptors, as well as high nonspecific binding (30 to 50 percent of total binding) (Leff et al., 1985), they have not been ideal tools for investigating D_1 receptor pharmacology, molecular mechanisms, or behavioral function.

Recently, a D_1 selective antagonist, SCH23390, was developed (Iorio et al., 1983) and has since been tritiated, making detailed D_1 receptor characterization possible. This novel benzazepine exhibits nanomolar potency in inhibiting dopamine stimulation of striatal adenylate cyclase activity (Battaglia et al., 1985; Onali et al., 1984), exhibiting a K_i value of approximately 0.5 nM for the striatal D_1 receptor (Billard et al., 1985). In contrast, its affinity for D_2 receptors is orders of magnitude lower (2×10^{-7} M) indicating that SCH23390 is selective for D_1 receptors. Hence, the advent of this first truly selective D_1 receptor antagonist has provided the tool for research into the functional correlates of D_1 receptor activation and antagonism.

Characterization of [^{3}H]SCH23390 Binding to D_1 Dopamine Receptors

We have undertaken a detailed investigation of antagonist and agonist interactions with D_1 receptors labeled by [^{3}H]SCH23390 and the effect of guanine nucleotides on the regulation of agonist interactions with this receptor (Hess et al., in press). In rat striatum, [^{3}H]SCH23390 binding is saturable, monophasic, and exhibits high affinity (K_d = 0.49–nM). Scatchard analyses of saturation data indicate that the site density in striatum, 64 ± 12.9 pmol/g wet weight tissue, corresponds well with densities reported for D_1 receptors labeled by [^{3}H]flupentixol (Hyttel, 1978; Leff et al., 1985). Antagonist competitions for [^{3}H]SCH23390 binding are monophasic, suggesting that [^{3}H]SCH23390 labels a homogeneous population of sites. That the affinities of antagonists' inhibition of [^{3}H]SCH23390 binding correlate well with their respective affinities in both inhibiting D_1 receptor binding of [^{3}H]flupentixol (Figure 1) or antagonizing dopamine-stimulated adenylate cyclase activity indicates that SCH23390 is D_1 receptor selective.

In contrast to the monophasic competitions by antagonists, agonist interactions with [^{3}H]SCH23390 binding were complex, yielding shallow competition curves. Agonist competitions consistently modeled best to two sites composed of a high affinity component (R_H) comprising 30 to 40 percent of the total

Log K_i values for [^{3}H]SCH23390 binding and [^{3}H]flupentixol binding were derived from data obtained in this laboratory (Hess et al., in press; Leff et al., 1985).

number of specific binding sites and a low-affinity site (R_L) comprising the remaining 60 to 70 percent of specific binding sites.

In many adenylate cyclase-coupled receptor systems, including D_2 receptors, α-2 and β-adrenoceptors, guanine nucleotides regulate agonist interactions with [^{3}H]antagonist-labeled receptors. The effect of guanine nucleotides, such as GTP, is primarily to reduce the overall affinity of agonists for these receptors (i.e., shift curves to the right) by reducing the percent of agonist high affinity binding (percent R_H). Consistent with these systems, we have found that in the presence of 0.3 M GTP, agonist competitions for [^{3}H]SCH23390 binding were shifted to the right and steepened, resulting in an approximate 50 percent reduction in the high-affinity agonist binding-site density. That guanine nucleotides can promote an apparent shift in agonist competition curves, decreasing the percent R_H without affecting total [^{3}H]SCH23390 binding suggests that the high- and low-affinity agonist components of binding represent partially interconvertible states of a single receptor population. This observation is consistent with the proposed two-state model, modified from the original ternary complex model (Boeynaems & Dumont, 1975). Briefly, this model hypothesizes that both agonists (A) and antagonists bind to the receptor (R) recognition site, but only agonists promote or stabilize the interaction between R and the guanine nucleotide regulatory subunit (N). Thus, a ternary complex is formed (ARN), representing the R_H state of the receptor. In this model, the addition of guanine nucleotides promotes the dissociation of N and R, representing the R_L agonist binding state.

Potential Clinical Utility Of SCH23390

Neuroleptics, administered to rodents *in vivo*, induce catalepsy, suppress conditioned avoidance responses, and antagonize the hyperactivity and stereotypy responses elicited by dopamine agonists. Neuroleptics are also generally antiemetic and have been shown to induce hyperprolactinemia by blocking dopamine receptors in the anterior pituitary. While SCH23390 is a selective D_1 receptor antagonist, this benzazepine surprisingly mimics some of the behavioral effects previously associated with D_2 receptor antagonists—such as blocking agonist-induced stereotypy and hyperactivity, as well as inducing catalepsy (Christensen et al., 1984; Iorio et al., 1983). However, SCH23390 neither antagonizes emesis nor produces hyperprolactinemia—indicating that SCH23390 administered *in vivo* is probably not acting as an antagonist at D_2 receptors.

That SCH23390 can induce these neuroleptic behavioral effects without blockade of D_2 receptors suggests that it may be an effective antipsychotic agent. Because chronic neuroleptic treatment in rodents produces an increase in the number of D_2 receptors (Fleminger et al., 1983), it has been suggested that the side effect of tardive dyskinesia seen following chronic neuroleptic treatment of schizophrenics may result from a selective D_2 receptor up-regulation (Cross et al., 1983). If chronic treatment with the D_1 receptor selective antagonist SCH23390 does not increase D_2 receptor number, it may therefore lack the liability to produce tardive dyskinesia.

Biochemical Effects of Chronic SCH23390 Administration

Indeed, in a preliminary investigation of this hypothesis (Creese & Chen, 1985) we found that after treating rats ($n = 6$) chronically with SCH23390 (0.5 mg/kg/day for 21 days), striatal D_1 receptors were significantly increased as determined by [^{3}H]flupentixol binding (B_{max} control = 56.6 ± 1.5 pmol/g tissue; B_{max} chronic SCH23390 = 70.3 ± 3.5 pmol/g tissue; $p = 0.005$) while no change was observed in the D_2 receptor population. In order to investigate this hypothesis further, we have examined the selectivity of SCH23390 administered *in vivo* for D_1 receptors, the effect of chronic SCH23390 treatment on adenylate cyclase activity as well as on dopamine receptor binding, and tested rats for their locomotor activity and stereotypy responses to selective D_1 and D_2 receptor agonists following chronic treatment with SCH23390.

After chronic treatment with SCH23390, an increase in D_1 receptors, as determined by [^{3}H]SCH23390 binding, was observed, consistent with the previous study by this laboratory (Creese & Chen, 1985). That no increase in D_2 receptors was observed indicates that this effect is D_1 receptor selective; thus, SCH23390 maintains its D_1 receptor specificity *in vivo* even after chronic treatment. This conclusion is supported by studies utilizing *in vivo* N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) treatment.

EEDQ has been shown to be an irreversible pharmacologic antagonist at a variety of neurotransmitter receptors. We recently demonstrated that peripheral administration of EEDQ results in a dose-dependent reduction in both D_1 and D_2 receptor binding (Hamblin & Creese, 1983). Significantly, treatment with SCH23390 (0.5 mg/kg, s.c.) prior to peripheral administration of EEDQ protects D_1 receptors from irreversible blockade by EEDQ, but neither D_2 nor S_2 serotonin receptors are protected from EEDQ-induced modifications by the SCH23390 pretreatment. This indicates that SCH23390, in all probability, interacts *in vivo* exclusively with D_1 receptors at the dose which was chronically administered to rats in our study. These data have been supported by Meller et al. (1985a) using a similar paradigm to examine the specificity of neuroleptics administered *in vivo*. That peripherally administered SCH23390 demonstrates selectivity for D_1 receptors suggests that the behavioral data reported herein are not confounded by any obvious nonspecific effects of this drug.

Interestingly, although the D_1 receptor B_{max} was increased by the chronic SCH23390 treatment, no change was observed in dopamine competition for [^{3}H]SCH23390 binding, nor was any change observed in the rightward shift of these agonist competition curves induced by guanine nucleotides. These data indicate that the coupling of the D_1 receptor to the guanine nucleotide regulatory protein is not perturbed following chronic SCH23390 treatment. That the R_H/R_L ratio remains constant between control and treated animals also suggests that there must exist some mechanism by which this ratio is maintained after receptor upregulation. Theoretically, if the population of N is stoichiometrically limiting (which is likely as 100 percent R_H is never induced by agonists) and R increases, the percent of high affinity agonist binding sites (R_H) should be reduced due to the percent decrease in potential R to N coupling. An excess or spare pool of N, however, would maintain the R_H/R_L ratio after receptor upregulation. Alternatively, if N is stoichiometrically limiting [as we have previously suggested (Battaglia et al., submitted)], N may also undergo concomitant upregulation with D_1 receptors, maintaining a constant R_H/R_L ratio. This may occur either through an increase in the actual population of N subunits or through an increase in the efficacy of the R/N coupling mechanism.

After chronic SCH23390 treatment, adenylate cyclase activity was enhanced by a small (9 to 13 percent) but significant amount. However, not only did dopamine-stimulated cAMP production increase, but guanine nucleotide and forskolin-stimulated adenylate cyclase activity also increased (Figure 2). It is important to note that dopamine-stimulated adenylate cyclase activity was increased by only the same percent as guanine nucleotide-stimulated adenylate cyclase activity. Furthermore, dopamine EC_{50}'s in control and tissue from chronically SCH23390 treated rats were identical. This indicates the increase observed in dopamine-stimulated adenylate cyclase activity most probably reflects the overall increase observed in guanine nucleotide-stimulated enzyme activity. The results of the agonist competition curves plus the adenylate cyclase data suggest that the guanine nucleotide regulatory protein, rather than the adenylate cyclase moiety, is in some manner "upregulated" with the receptor.

That no percentage increase is observed in dopamine-stimulated adenylate cyclase activity after D_1 dopamine receptor upregulation is, at first examination, surprising. However, in other experiments we have demonstrated the existence of "spare" D_1 receptors in the striatum of normal control rats explaining this observation (Hess et al., submitted). In these experiments we again utilized peripheral administration of the irreversible protein-modifying reagent, EEDQ. After *in vivo* EEDQ treatment, no change in adenylate cyclase stimulation above basal activity is observed in the presence of the putative Ns effectors GTP, Gpp(NH)p, and NaF. Likewise, stimulation by forskolin, thought to act directly at the catalytic subunit, is unaltered by EEDQ administration. However, we have found that both the D_1 receptor binding of [^{3}H]SCH23390 and adenylate cyclase stimulation by dopamine are markedly reduced after *in vivo* EEDQ treatment in a dose-dependent manner (Figure 3). Thus, peripherally administered EEDQ acts in a receptor-specific manner, but leaves Ns and the catalytic subunit of adenylate cyclase intact.

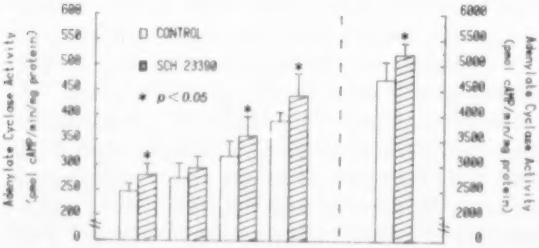

FIGURE 2. Adenylate cyclase activity in control and chronic SCH23390 treated tissue. Bars represent mean + SDs of dopamine and forskolin-stimulated cAMP production in the presence of 100 μM GTP. Asterisks denote adenylate cyclase stimulation in chronic SCH23390 treated tissue significantly greater than control tissue, $p < 0.05$.

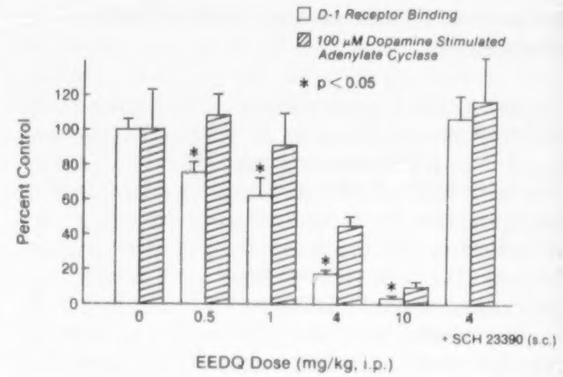

FIGURE 3. Dose-dependent reduction in D_1 receptor binding and receptor-mediated stimulation of adenylate cyclase after peripheral administration of EEDQ. Open bars represent the mean + SEM of [^{3}H]SCH23390 B_{max} values as a percent of the control B_{max} (47 ± 7 pmoles/g tissue) and hashed bars the mean + SEM of the differences between stimulation by 0.1 mM GTP alone and stimulation by 100μM dopamine + 0.1 mM GTP as a percent of stimulation in controls (186 ± 45 pmoles cAMP/min/mg protein). EEDQ-induced reductions were prevented by pretreatment with SCH23390 (0.5 mg/kg s.c.), denoted by bars labeled + SCH23390 (s.c.). Asterisks denote percent B_{max} significantly less than percent dopamine-stimulated adenylate cyclase, $p < 0.05$.

Because the Ns and catalytic moieties are not functionally modified, peripheral EEDQ administration may be used as a tool to assess the stoichiometry of D_1 receptor/effector interactions. That is, by progressively blocking increasing numbers of receptors and monitoring adenylate cyclase activity, the loss of D_1 receptors may be correlated with a decrease in D_1 receptor-mediated stimulation of adenylate cyclase activity. Interestingly, we have found that approximately 40 percent of D_1 receptor binding may be lost with no significant reduction in the V_{max} of dopamine-stimulated adenylate cyclase activity. That is, only approximately 60 percent of the original D_1 receptor population is necessary for full *in vitro* agonist-stimulation of adenylate cyclase activity. Thus, these data suggest that the D_1 receptor population is not a stoichiometrically limiting factor in agonist-stimulation of adenylate cyclase.

This finding has important neurophysiologic implications. Receptor occupancy is determined by transmitter (or drug) concentration. Since only ~60 percent occupancy of the normal D_1 receptor population is required for maximal effector stimulation, the transmitter concentration necessary to elicit full stimulation ($\sim 2 \times K_D$) is considerably less than that concentration necessary for 100 percent receptor occupancy ($100 \times K_D$). The existence of these "spare" receptors, then, potentially enhances neurotransmission by reducing the effective concentration of dopamine required to diffuse across the synaptic cleft to achieve a full response.

In light of this finding, it is not surprising that a ~20 percent increase in D_1 receptors after chronic SCH23390 treatment did not increase the receptor-stimulated adenylate cyclase activity since ~40 percent of the normosensitive D_1 receptor population may be considered "spare." Receptor upregulation, then, probably does not act directly to increase cAMP production but rather supersensitivity is manifested by reducing the effective transmitter (or drug) concentration necessary to induce a maximal response. That is, by increasing receptor number, the percent receptor occupancy necessary to activate a full effector response is reduced. Collectively, these pharmacologic and biochemical data suggest that in addition to a dopamine receptor selective upregulation, an additional upregulation also occurs at the level of either the guanine nucleotide regulatory subunit or perhaps the catalytic subunit of adenylate cyclase, leading to the small overall increase in cAMP production.

Behavioral Effects of Chronic SCH23390 Administration

Unlike chronic neuroleptic treatment, where neither an increase nor decrease in spontaneous locomotor activity was observed (Tarsy and Baldessarini, 1974), rats chronically treated with SCH23390 (0.5mg/kg/day s.c. for 21 days and withdrawn for 2 days) demonstrated a more than twofold higher level of locomotor activity than control animals during habituation to the locomotor cages ($p < 0.02$). Paralleling the habituation results, again in contrast to classic neuroleptics where tolerance develops to their cataleptogenic effects after chronic treatment (Ezrin-Waters & Seeman, 1977), rats receiving chronic administration of SCH23390 for 21 days demonstrated no tolerance to its cataleptogenic action. This suggests that the neuronal network through which chronic SCH23390 elicits its effects is different from and is not regulated in the same manner as the neuronal network through which classic neuroleptics exert their effects.

Other research supports this hypothesis. After treatment with either D_1 or D_2 selective agonists, unilaterally 6-OHDA lesioned rats demonstrate contralateral circling behavior (Arnt & Hyttel, 1985) and reserpinized animals demonstrate hypermotility and oral sterotypy (Arnt, 1985a). In these cases, although similar behaviors were induced by the D_1 and D_2 receptor agonists, behaviors induced by D_2 agonists were blocked only by D_2 antagonists and similarly, D_1 antagonists only blocked D_1 agonist responses. These data suggest that although D_1 and D_2 receptor-mediated behaviors may be overtly similar or even identical, they are independently modulated and can be distinguished from each other through these various pharmacologic treatments.

In concert with these data, the chronically SCH23390 treated rats responded to the selective D_1 receptor agonist, SKF38393, with potentiated locomotor behavior. However, the magnitude and time course of the locomotor activity after SKF38393 administration was identical to the activity response seen in habituation for both groups. Thus, it is unclear from these data whether the chronically SCH23390 treated rats are indeed showing an enhanced response to SKF38393 itself, or simply exhibiting an enhanced spontaneous response to handling. However, the stereotypy observations clearly indicate that chronic SCH23390 does enhance the behavioral response to SKF38393. As seen in Figure 4, chronic SCH23390 treated rats showed a more intense stereotypy response to SKF38393 than did the chronic saline treated rats. Unlike mixed D_1/D_2 agonists, SKF38393 induced stereotyped grooming in both groups of rats. However, grooming quickly diminished in control rats and they demonstrated more locomotor stimulation. The chronic SCH23390 treated rats, how-

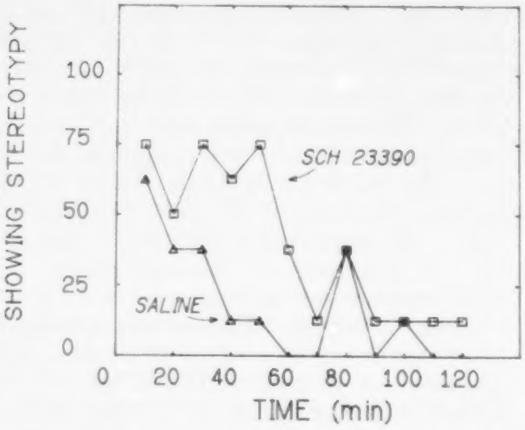

FIGURE 4. Mean stereotypy response to 3.0 mg/kg (s.c.) SKF38393 of rats chronically treated with SCH23390 (0.5 mg/kg/day s.c. for 21 days) or saline. The SCH23390 treated rats demonstrated an overall greater stereotypy response ($p < 0.005$, Information Statistic) as rated on the scale of Creese and Iversen (1975).

ever, continued to groom and/or show stereotyped sniffing and rearing in one location over the first hour in response to SKF38393.

Surprisingly, a similar potentiation in locomotor activity and stereotypy was observed in chronically SCH23390 treated rats after treatment with quinpirole (LY171555), a selective D_2 agonist. The locomotor responses to quinpirole (Figure 5) in both groups was quite different from their habituation response clearly indicating that the locomotor response to quinpirole is enhanced by the chronic SCH23390 treatment. The time course of the response, initially low, peaking and dropping away is explained by the stereotypy ratings (Figure 6). Quinpirole initially induced intense stereotyped sniffing and rearing in one location in both groups. Between 50 and 80 min post injection, some chronic SCH23390 treated rats, but no control rats, also showed stereotyped licking of the cage. The peak in crossovers at 140 min corresponded to the transition from stereotyped behavior in one location to locomotor activity. Surprisingly, locomotor activity was quickly attenuated in the chronically SCH23390 treated rats and each rat "instantaneously" went from "sniff/locomotion" to "freezing" in position. This frozen posture was maintained for 5 to 10 min before the rats closed their eyes and apparently went to sleep. Control rats did not show this freezing behavior. This response may potentially prove to be a useful model for the "on-off" phenomenon seen during dopamine agonist treatment of Parkinson's disease. One might speculate that this troublesome side effect

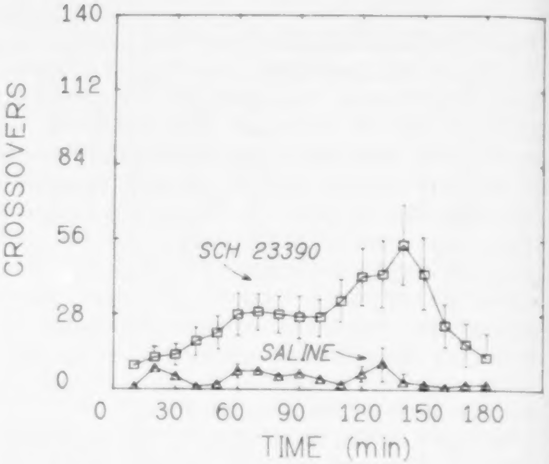

FIGURE 5. Photocell beam crossovers to 0.3 mg/kg (s.c.) quinpirole after habituation in rats chronically treated with SCH23390 or saline. The response of the SCH23390 treated rat was significantly higher ($p <$ 0.005 ANOVA).

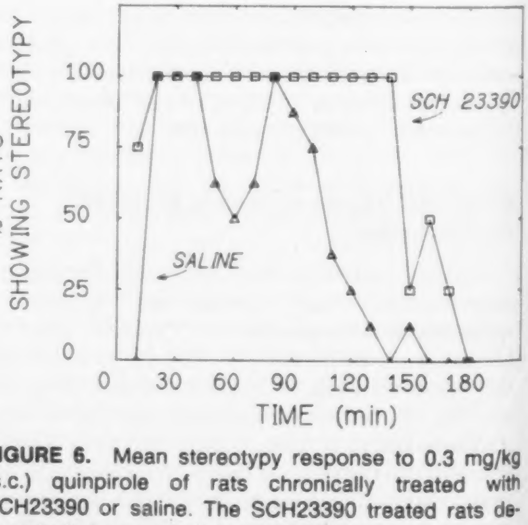

FIGURE 6. Mean stereotypy response to 0.3 mg/kg (s.c.) quinpirole of rats chronically treated with SCH23390 or saline. The SCH23390 treated rats demonstrated an overall greater stereotypy response ($p < 0.005$, Information Statistic).

may result from the upregulation of D_1 receptors in this disease.

Thus, the behavioral effects of a D_2 agonist are potentiated after a selective D_1 receptor upregulation. Certainly this is an anomalous response given that SCH23390 has no *direct* effect on D_2 receptors *in vivo*. Paralleling the results presented herein, it has been demonstrated that although SCH23390 acts as a D_1 receptor antagonist, inducing catalepsy in rats, pretreatment with selective D_2 dopamine receptor agonists prevents this response in a dose-dependent manner (Meller et al., 1985b). Likewise, the behavioral effects of the D_1 receptor agonist, SKF38393 could be partially reversed by the D_2 receptor antagonist metaclopramide (Molloy & Waddington, 1985). These behavioral data, then, suggest that D_1 and D_2 receptor-activated neuronal systems are not functionally isolated. Rather, the behavioral data presented herein suggest that although the networks through which D_1 and D_2 receptors mediate behavioral effects appear to be functionally independent (i.e., separate, parallel systems), these systems are interactive in their modulation of motor function.

Clinical Implications

One must always be careful in drawing conclusions from animal behavioral and biochemical data that pertain to the clinical situation. With this caveat in mind, some points can be made: (1) If SCH23390 proved to be antipsychotic, its chronic use may still lead to tardive dyskinesia since following SCH23390 treatment the behavioral response to both D_1 and D_2 selective agonists is increased—even though there is a selective increase in only D_1 receptors. (2) Classic neuroleptics demonstrate tolerance to their cataleptogenic action and for their induction of acute Parkinsonian extrapyramidal side effects. Since we did not see tolerance to the cataleptic action of SCH23390, it may well continue to induce Parkinsonian side effects during clinical use. However, the validity of these animal models must be questioned for their relevance to the clinical situation. Thus, the study of SCH23390 in clinical trial may be the only tool to determine the validity of these animal models and the utility of this novel drug in the clinical situation.

> Early learn to appreciate the differences between the descriptions of disease and the manifestations of that disease in an individual, the difference between the composite portrait and one of the component pictures.
>
> Sir William Osler—*Counsels and Ideals and Selected Aphorisms*

In the first half of this century medical students were warned never to invoke more than one diagnosis to explain a given clinical picture, no matter how myriad and complex its presentation. This admonition was known as Osler's Dictum, and represented the first principle of differential diagnosis. The second half of this century has repealed Osler's Dictum. Increased life-span, radical surgeries, long-term maintenance treatments with complex and toxic pharmacological agents, and a host of other modern medical variables have created patient populations who routinely present the physician with the simultaneous effects of two or three concomitant illnesses. Now, untidy problem-oriented methodologies have replaced the pleasing elegance of Osler's Dictum.

Mixed mania, the simultaneous experience of significant symptoms of depression and mania, creates a similar dilemma for modern psychiatric diagnostic systems. These parallel dilemmas exist even though Oslerian diagnoses (and medical diagnoses in general) are inherently hypothetical, whereas psychiatric diagnoses, with their reliance on operational criteria, are antihypothetical and descriptive. Indeed any illness that meets operational, descriptive criteria for manic-depressive illness *is* manic-depressive illness and complicating factors can be, and usually are, separated off onto another diagnostic axis, as if they "Lethe ward had sunk." All that is left is a peculiar, psychiatric distillation of Osler's Dictum.

Mixed mania, however, does not tolerate this distillation process very well. In this paper we will present evidence derived from 130 subjects with mixed mania (84 reported in two earlier papers, and 46 new cases) which will show that mixed mania is a phenomenologic entity that occurs frequently enough to considerably complicate both the diagnosis and treatment of manic-depressive illness. Mixed mania has a major impact on the biological theories of bipolar disorders; it reflects the influence of a host of neurological, pharmacological, medical, and characterological factors on the clinical manifestation

of manic-depressive illness; it is, diagnostically speaking, chameleon-like in presentation—appearing in some people like schizophrenia, in others like psychotic depression, and in still others like labile, hysteroid states—thereby creating a set of differential diagnostic conundra. And, finally, it resists treatment intervention with any pharmacologic agent, particularly lithium salts.

Our data will allow us to hypothesize some of the sources of mixed mania and of lithium resistance. We will also demonstrate the relative effectiveness of carbamazepine regimina in the treatment of mixed mania. Of special interest is the frequent incidence of both mixed mania and lithium resistance in adolescent bipolar populations (age 12–19) discovered by the second author of this paper (M.G.), as part of a larger systematic study of carbamazepine treatment of adolescents with manic-depressive illness (Garfinkel et al., 1985).

Methods

Our early investigation was carried out on 84 bipolar patients taken from 143 consecutive admissions to Affective Disorders Clinics at Yale University Medical Center and at the University of Pittsburgh (Himmelhoch et al., 1976; Himmelhoch, 1979). Diagnoses were made according to the criteria of Feighner (1972) and data were collected and analyzed by use of the Kupfer-Detre System (KDS) (Kupfer & Detre, 1970). Those patients who in their initial episode demonstrated simultaneous significant mania (score greater than 12) and depressive (score greater than 18) symptom clusters were considered to be experiencing a mixed manic episode. Our recent study focused on 46 lithium resistant bipolar patients. These patients were diagnosed according to the Diagnostic and Statistical Manual-III criteria. Patients from this group with a simultaneous 21-item Hamilton Depression Score of greater than 16 and a KDS-mania score of greater than 12 were designated as mixed manic. Thirty-seven of the 46 met these criteria. Treatment outcome in both groups was considered good if both manic and depressive scores returned within 2 months to the normal range for the given measurement instrument and stayed within the normal range during the entire follow-up period. Response was considered poor if the patient's original mood swing (manic, depressed, or mixed) did not return to the normal range within 2 months or if at any time during the follow-up period the patient experienced a significant new mood swing as scored on the same measurement instruments. Follow-up periods ranged from 6 months to 14 years, and were greater than 18 months in 88/130. Both diagnosis and treatment outcome were carefully correlated in all 130 patients with standard demographic variables and the presence or absence of sedative and alcohol abuse. In addition the second group of 46 were carefully studied to ascertain the presence or absence of neuropsychiatric factors such as seizures, paroxysmal electroencephalograms (EEG), severe head injuries, migraine, perinatal insults, hyperactivity and learning disorders.

The Incidence and Significance of Mixed Mania in a Bipolar Population

Mixed mania was first described by Kraepelin:

> You see here before you a student of music aged nineteen, who has been ill for about a year. . . without any tangible cause he became depressed, felt ill at ease and lonely, made all manner of plans, which he always gave up, changing his place of residence and his profession, for he could come to no fixed resolution. During a visit to Munich, he felt as if people in the street had something to say to him, and as if he were talked about everywhere. He heard an offensive remark in an inn, which he answered angrily. Next day, he was seized with the apprehension that his remark might be taken as *lèse majestè*. . . . Since then he overheard people in the street who threatened to shoot him, and to set fire to his house, and on that account he burned no light in his room. In the streets, voices pointed out the way he ought to go so as to avoid being shot. He also heard long conversations of not very flattering purport as to his person. . . . After about six months he felt more free, comfortable, enterprising, and cheerful, began to talk a lot, to compose, criticized everything, concocted great schemes, and was insubordinate to his teacher. . . . The interpretation of this condition is not easy at first glance. Of the diseases hitherto considered, dementia praecox would perhaps come first and foremost under consideration. But the exceedingly fresh and active mood of the patient, his interest in his surroundings, his sociability and his press of occupation are de-

> cidedly opposed to this supposition. . .[all] points to the relationship of the condition with maniacal-depressive insanity. *And this opinion would be justified by the joyless irresolute manifestations of the first stage, passing into the comfortable but active states, so noticeable in the second stage.* (Kraepelin, 1968)

As is often the case there is little new one can add to a Kraepelinian *Urfall* (original case description). His depiction of underlying intense dysphoria, of rapid, unpredictable shifts in motor activity, and of oscillations in the efficiency of information processing nicely catch the heteronymous nature (Kleist, 1926) of mixed mania. If the clinician fails to note the *marche* of a mixed manic episode, that merging of an anhedonic first stage into a manic second stage, but concentrates instead on the signs and symptoms present at any one point in time (on a *tranche du mal*, as it were) schizophrenia would indeed come first and foremost to mind. Mixed mania can be equally misleading in its non-psychotic presentation. In our initial investigation (Tables 1, 2, 3), 26 of 84 patients (31 percent) were admitted with mixed mania (Himmelhoch et al., 1976). Fourteen presented the psychotic picture described by Kraepelin. The remaining manifested variable neurotic syndromes made up of unpredictably occurring turns of dysphoria, irritability, elation and anergia, appearing in one patient like atypical depression, in another like hysteriod dysphoria and, surprisingly, in a few like panic disorder (Himmelhoch, 1984). Kraepelin never described these low-grade forms of mixed mania. The distinction between Kraepelin's *Urfälle* and these non-psychotic disorders may have considerable theoretical importance, because our subsequent findings indicate that the non-psychotic syndrome may have different origins from the psychotic presentation of mixed mania.

TABLE 1. Frequency of Mixed States in Manic-Depressive Illness.

Type	Number of Patients	Percent
Mixed states	26	31 percent
Non-mixed states	58	69 percent

	Drug Abuse	No Drug Abuse
Mixed states	12	14
Non-mixed states	11	47

$\chi^2 = 13.95$, $p < .001$.

The 31 percent incidence of mixed manic presentations (Table 1) in our population is similar to the incidences reported by Winokur et al. (1969) and Nunn (1979). Subjects with mixed mania differed from subjects presenting with pure depression or with pure elation in two ways. First, the incidence of alcohol and sedative abuse was significantly higher in the mixed patients (Table 2). Alcohol and sedative abuse were defined according to criteria given in earlier papers (Himmelhoch et al., 1976; 1980; 1983). Second, mixed manics had significantly worse treatment outcome than did typical bipolar subjects (Table 3). Part of this lesser treatment outcome was explained by the deleterious impact of alcohol and sedative abuse on the mixed patients treatment response. However, first order, partial correlation showed that mixed mania still had a significant negative effect on outcome even after the negative effects of alcoholism and sedativism had been partialled out. Fifteen of 26 mixed subjects had poor treatment outcome. Only 4 of these

15 did not abuse sedatives or alcohol. Of the 14 with psychotic features similar to those described in Kraepelin's *Urfall*, 10 had a good response to treatment. Conversely, only 1 of 12 non-psychotic mixed manics had good outcome on lithium based treatment regimina. These findings suggest that there are two clinical parameters important to the production of mixed mania; the first, severity of illness; the second, the presence of a complicating neuropsychiatric variable that lends a significant dysphoric coloration to a manic or hypomanic episode. It is only the severely ill, uncomplicated, bipolar patients whose illness follows the process described by Kraepelin as generative of mixed mania, i.e., an anhedonic first stage of illness merging into a hypomanic-manic second stage. By no means do all manic-depressive patients repeatedly follow this sequence as they become manic. Nevertheless, Court (1968) and Bunney et al. (1972) have used this two-stage process, along with the existence of mixed states themselves, as evidence for what has become known as the continuum hypothesis of manic-depressive illness.

The continuum theory denies the usual notion that mania is a polar opposite state to depression, as is implied by the term "bipolar illness," so often used as a synonym for manic-depressive illness. Instead the continuum hypothesis posits that depression and mania are closely related entities that are, in all likelihood, only *quantitatively* different. Depression represents mild to moderate illness, and mania severe illness. Mania is viewed as a state with a depressive core. Therefore, any given patient, as he gets more severely ill, passes from depression through a mixed manic phase into pure mania. Bunney et al. (1972) feel that the rapid switch from depression to mania usually includes a brief normal period, often overlooked because there is usually no opportunity to continuously observe these patients. They offer a variation of Court's continuum, an extension of Prange's (1973) "serotonin-permissive" hypothesis: ". . . which includes both an underlying dysfunction and a superimposed dysfunction. The underlying dysfunction, present during both depressive and manic phases, may not be related to catecholamine function."

Court's hypothesis, however, seems preferable because it explains both mixed states and rapid cycling. But in all variations of this hypothesis mania is viewed as a state with a depressive core: mixed mania represents a transitional phase occurring as depression "switches" to mania (the switch process) and the patient becomes trapped in the switch phase. The whole continuum is a complex psychobiological restatement of the psychoanalytic observation that mania is the pathological extension of the very human process of denying depression (Himmelhoch, 1979). Elation can represent a failing organism's last gasp attempt at adaptation and survival, when all that is left to it is a frail tissue composed of absolute denial, cheerful delusion, exaggerated religiosity, and desperate drivenness (Himmelhoch, 1986). Sometimes, the *masque* succeeds: Solshenitzen observed in *Gulag Archipelago* that any given Zek's (shortened Russian form of the word zaklyuchennye or prisoner) survival depended directly on his abilities to mobilize hypomanic denial and no wise physician would interfere if he saw this same maneuver employed by a cancer patient undergoing chemotherapy. But just as often the defense mechanism fails, and then the psychotic and delusional nature of the organism's denial becomes readily apparent, and worse yet, underlying protest and despair, the depression at denial's core, wells up through cracks and crazes of an imperfect defensive structure. Here, perhaps, is an ethological source of mixed mania. And there exists a fair amount of biochemical (Coppen, 1965; Dunner et al., 1971), endocrinologic (Sachar et al., 1971; 1970), genetic (Winokur, 1970), perceptual-motor (Buchsbaum et al., 1971; Court & Mai, 1970; Beigel & Murphy, 1971), clinical (Rosenfield, 1973), and psychopharmacological (Prange, 1973; Dyson & Mendels, 1968) evidence that mania and bipolar depression are, in many ways, similar psychophysiologic states. Mixed mania is the phenomenologic *sine qua non* of all these fascinating theorizations.

But, although the continuum hypothesis and its variations seem helpful in explaining mixed mania in some manic-depressive patients, the incidence and clinical correlates of this phenomenon imply heterogeneity, not only of mixed mania but of manic-depressive illness itself. In the first place the incidence of mixed mania is 40 percent at most, and even assuming that certain patients who have not experienced mixed mania eventually will at some time during the course of their illness, one can readily deduce that at least 50 percent of manic-depressive patients will only experience pure episodes. Moreover, in a recent investigation, Nunn (1979) has demonstrated that the sequence described by Kraepelin, where anhedonia switches into mania, is not experienced by every patient in whom mixed mania develops; nor does a manic patient always pass backwards through the phases of the continuum when he recovers. Nunn hypothesizes that some mixed states arise from the impingement of another illness (in his thinking another type of depression) on core manic-depressive illness. Himmelhoch et al. (1976) had already suggested this mechanism, but described sedative abuse as the "second factor" necessary to the provocation of a mixed affective state. "Drug abuse (particularly alcohol and sedatives) alters the clinical presentation of manic-depressive swings, and . . . the impact of over-sedation or withdrawal or both on a 'pure elation' is to make it dysphoric or mixed."

Our most recent investigation of 46 lithium resistant bipolar patients not only shows that mixed mania is a major clinical correlate of lithium resistance, but that a second neuropsychiatric factor is a consistent correlate of mixed mania. In addition to alcoholism and sedativism (15/46 patients) demonstrated in our earlier work, second factors such as seizures, paroxysmal EEG's, classical migraine, history of severe head injury, significant perinatal insults, hyperactivity, or clear-cut learning disorders were demonstrated in a preponderant majority of these patients. Indeed, it became evident from our second investigation that alcoholism and sedativism are only representative of the many forms of cerebral insufficiency which serve as the substrate for the development of mixed mania. Thirty-seven of the 46 lithium resistant patients had mixed mania and 31/37 had significant second neuropsychiatric factors. The distribution of these factors is shown in Table 4. Although only 9/46 lithium resistant patients had "pure" presentations, the association of a second neurological condition with mixed mania was still highly significant ($\chi^2 = 13.83, p < .001$).

TABLE 4. Distribution of Second Neuropsychiatric Factors.*

	Mixed	Non-Mixed

Significant head injury	4	1
Developmental disorders	8	2
Neurological illness**	2	0
Alcohol/Drug abuse	12	3

*Numerous subjects had greater than one second factor.
**Benign adenoma of the pituitary and Sydenham's Chorea.

When both investigations are combined, a total of 63 patients had mixed manic presentations. Eighteen (14 from the original study and 4 in the second group) had uncomplicated bipolar illness that fit the continuum model and 10 of these responded to lithium plus an antidepressant. Forty-five had second neuropsychiatric factors (albeit, in the first investigation drug abuse was the only complicating factor recorded). Only 1/45 such patients responded to a lithium based treatment regimen. This difference in outcome ($\chi^2 = 25.38, p > .001$) is highly significant.

Thus, lithium resistance in mixed mania can be seen to rise from two sources; first, from the greater severity of bipolar illness that fits the continuum model; and, second, from superimposed neuropsychiatric illnesses that greatly complicate treatment. It is important to note that the majority of patients (34/45) who have mania correlated with second neurological factors, had non-psychotic clinical presentations. Under ordinary circumstances their manic-depressive illness would have been mild and easily treatable. In general, such patients have milder illnesses which do not fit the continuum model. They do not experience rapid cycling and only rarely exhibit psychotic elation. Usually they enjoy productive hypomanic periods which are separated from their depressive episodes by long spells of euthymia. *There is no depressive core to their hypomania* (Himmelhoch, 1986). Their lesser prognosis is generated by a second illness, because it is a geometrically more difficult task to effectively treat two coexisting illnesses. On the other hand, continuum model manic-depressive illness, which spontaneously generates mixed mania through the organism's last gasp mobilization of denial, is, under ordinary circumstances, a completely different and more severe kind of manic-depressive illness than the milder, interrupted, "true bipolar" syndrome. Indeed, continuum model illness is much akin to a neurological disorder such as temporal lobe epilepsy or a mild dementia. In attempting to explain the difference between the neurologically normal and the neurologically abnormal organism, Kurt Goldstein (1971) concluded:

> . . . whenever anxiety, as the mainspring of an organism comes into the foreground, we find that something is awry in the nature of that organism. To put it conversely, an organism is normal and healthy when its tendency toward self-actualization issues from within and when it overcomes the disturbance arising from its clash with the world, not by virtue of anxiety but through the joy of coming to terms with the world.

In the end, both sources of mixed mania may boil down to relative cerebral insufficiency.

Mixed Mania and Adolescence

Twenty-three of the 46 lithium resistant patients were adolescents (between ages 12 and 19). A detailed report about their clinical characteristics already has been presented. Table 5 shows the relationship, first of drug abuse then of "second neuropsychiatric factors," to mixed mania in this adolescent population. Unlike adults, adolescents showed no significant association of drug abuse with mixed mania (although 8/23 were addicted to sedatives and/or street drugs). This association is evidently washed out by the almost inevitable presence of concomitant neuropsychiatric disorders. As with the 23 adult lithium-resistant patients, the correlation of second factors to mixed mania was powerful (Fishers two-tailed, $p = .002$), even though only six adolescents presented with pure affective episodes. Six mixed adolescents had two "second factors" (10/45 of the total patients with mixed mania had two or more "second factors"). The severity of illness and the lithium resistance shown by these patients is reflective of our general experience with manic-depressive illness in adolescent populations. The developmental immaturity and inadequate defensive structure of adolescents interact in some way with the genetic *anlage* of manic-depressive illness to foster both the mixed mania and lithium resistance. A few adolescents respond well to lithium regimina, although almost none respond to lithium alone. A majority, moreover, require complex pharmacologic treatment programs involving carbamazepine and lithium salts. Antipsychotics, tricyclics, and/or monoamine oxidase inhibitors are often necessary adjuncts. On occasion, unusual interventions including clonidine, clonazepam, calcium channel blockers, sodium valproate, phenytoin, etc., are indicated. Severe, dysphoric mixed manias often give rise to suicidality and may require electroconvulsive therapy. Patience, empirical tinkering, frequent clinical contact, and the careful monitoring of critical blood levels and other related laboratory variables are the *sine qua non* of successful management.

Treatment of Mixed Mania

Mixed mania represents the rare situation where poor prognostic bipolar patients do better on lithium regimina, because better prognostic bipolar patients with mixed mania actually present the clinician with two illnesses—a good prognosis, true bipolar ill-

ness, and a second neurological condition which simultaneously decreases cognitive abilities and increases dysphoria. Ten of 18 "continuum model" manic-depressives, therefore, responded to lithium based treatments (all needed adjunctive antidepressant and some needed adjunctive neuroleptics). Forty-four of the 45 mixed manias with concomitant neuropsychiatric disorders, and the 8 lithium resistant, continuum-model patients required treatment regimina based on anticonvulsant therapy (all but 4 carbamazepine-based). In our second study, 21/46 mixed manics had a good response to anticonvulsant based therapy, as compared to 8/9 patients with "pure" presentations ($\chi^2 = 3.2$, $p < .07$) showing that even in a lithium-resistant population the presence of mixed mania produces a trend towards a worse outcome. However, six of our carbamazepine failures were found in the adolescent population. These six had an initial slow and incomplete response to carbamazepine plus lithium, but stabilized on this regimen after 6 to 12 months. Although they failed to meet our research definition for a good response, it is likely they were carbamazepine responders. The management of adolescents on carbamazepine is a complicated situation, requiring frequent dosage changes. Adjunctive lithium is almost always necessary. Indeed, the management of any patient with mixed mania is a challenge to the persistence and to the pharmacological skill and imagination of the clinician.

Conclusion

Mixed mania occurs either in severely ill, continuum-model, manic-depressive patients (uncomplicated mixed mania) or in "true bipolar" patients whose illness has been complicated by a second neuropsychiatric condition, especially sedative abuse or epileptic changes (complicated mixed mania). All mixed manias tend to be lithium resistant, but uncomplicated mixed mania responds significantly better to lithium regimina than does complicated mixed mania. Mixed mania often responds well to anticonvulsants, especially carbamazepine, as might be deduced from the clinical correlates of mixed mania. However, as reported by Ballenger and Post (1980) and Okuma and Kishimoto (1977) in a majority of cases, carbamazepine must be combined with other psychopharmacologic agents—especially lithium and/or antidepressants—to obtain optimal clinical response. Early onset manic-depressive illness seems particularly prone to manifest itself as severe, lithium resistant, and mixed. Here again, carbamazepine-lithium combination is the most effective pharmacological intervention—but it often takes 6 to 12 months of careful follow-up and frequent drug adjustment to stabilize adolescent patients. The findings of both of our investigations seem to suggest that any phenomenon which significantly compromises central nervous system integrity, including developmental immaturity, frank neurological illness, or substance abuse and addiction, may result in the production of mixed mania.

Expressed Emotion, Maintenance Pharmacotherapy, and Schizophrenic Relapse Among Mexican-Americans[1]

Janis H. Jenkins, Ph.D., Marvin Karno, M.D., Aurora de la Selva. M.Ed.Psych., Felipe Santana, Ph.D., Cynthia Telles, Ph.D., Steven Lopez, Ph.D., and Jim Mintz, Ph.D.[2]

While there is a pressing need for valid epidemiological studies, current evidence suggests that schizophrenia afflicts persons the world over (Kennedy, 1974; Murphy, 1982; World Health Organization, 1979). However, a growing body of literature has documented significant cross-cultural variations in the course and outcome of schizophrenia. The most systematically collected data for this observation has been gathered by the World Health Organization's International Pilot Study of Schizophrenia (IPSS). In that study, 1,202 patients from Nigeria, India, Colombia, Taiwan, the United Kingdom, the United States, the U.S.S.R., Czechoslovakia, and Denmark were followed for a 5-year period. Findings at the time of 2-year followup indicated a markedly superior course of illness for patients from the developing countries relative to outcomes observed for patients residing in more industrialized nations (World Health Organization, 1979).

There has been some speculation that pharmacological influences might explain these findings. For example, in a review of the IPSS data collected for Nigeria—the African nation where the most favorable of outcomes were observed—anthropologist Robert Edgerton (1980) has drawn our attention to several possible sources of explanation for the IPSS results, including pharmacological and sociocultural factors. Edgerton observed that

> [i]n addition to receiving phenothiazines during treatment at a Western psychiatric center, patients in the Ibadan sample may have received psychoactive medications, including neuroleptics, from native healers either before admission to a treatment center, or after release. Rauwolfia alkaloids are still used by Yoruba native heal-

> ers, as are many other drugs . . . which could have neuroleptic properties. . . . (1980:175–176).

Since the IPSS investigators did not provide specific data concerning the use of drugs by the Nigerian patients, however, it is not possible to ascertain the effects of such pharmacological influences. While drug information available for the other IPSS developing countries is sketchy, the available data would seem to indicate that the variance in outcome cannot be explained by unexamined neuroleptic effects (World Health Organization, 1979:104–106). Rather, as the IPSS investigators concluded, it is possible that the observed differences in course and outcome can be explained by features of the sociocultural environment (Sartorius, Jablensky, & Shapiro, 1978).

Moreover, the existence of other (albeit less rigorous) reports of favorable schizophrenic outcome in non-Western settings supports the plausibility of the IPSS conclusion. Such additional observations have been recorded for China (Rin & Lin, 1962), Africa (Jilek & Jilek-Aall, 1970; Kennedy, 1974), Mauritius (Murphy & Raman, 1971), and Sri Lanka (Waxler, 1977). These researchers, along with investigators of the IPSS, have suggested that familial and societal patterns of response to an ill individual may influence the course of illness. For example, it has been hypothesized that families who respond to an ill family member with tolerance and acceptance might contribute to a more benign course for schizophrenic illness.

Our research was undertaken to examine this hypothesis concerning family influences on the course of schizophrenia among Mexican-Americans. The study was designed to further British research initiated by George Brown and his colleagues. Their work represents the most systematic and significant line of research documenting the importance of family life on the course of psychiatric illness (Brown, Birley, & Wing, 1972). While these investigators are careful to point out that they make no etiological assumptions about the familial emotional climate and schizophrenic onset, a high degree of "expressed emotion" (EE)—as indexed by criticism, hostility, or over-involvement on the part of family members toward their schizophrenic relatives—was found to be significantly associated with a poor course of illness.

Subsequent studies of EE among British and Anglo-American families have replicated the initial British findings (Vaughn & Leff, 1976; Vaughn et al., 1984). While such studies have provided necessary corroboration of the British results, the question of the cross-cultural validity of the EE index and its prognostic importance for other culturally distinct groups remained unanswered. Our work has attempted to shed light on the relationship of EE and schizophrenic illness within a Mexican-American family context, one which is culturally and linguistically quite distinct from those of the British and Anglo-American samples. Given the potential importance of sociocultural factors for schizophrenic outcome, it seems essential for reasons both theoretical and applied that we study a range of culturally diverse populations. Mexican-Americans, as well as the myriad of other culturally distinct populations in the United States, continue to be notably under-represented in clinical studies, including schizophrenia research.

In our research project entitled "The Course of Schizophrenia Among Mexican-Americans" (COSAMA), patients were followed for 9 months subsequent to hospitalization for an acute psychotic episode. The major findings of this study will be reported upon here in abbreviated fashion. (For more detailed reports of the study and these data, the reader is referred to lengthier publications by Karno et al., in press; Jenkins et al., 1986; Jenkins, in press. Additional reports are forthcoming.)

Sample and Methods

The patients included in the study met the following selection criteria: (1) of Mexican birth or bilateral Mexican descent; (2) between 18 and 50 years of age; (3) hospitalized for an acute psychotic episode; (4) diagnosed as suffering from schizophrenia according to Present State Examination (PSE) and DSM-III criteria; (5) living with a family before and after hospital admission.

Assessment Procedures

Patients were diagnostically assessed using the Present State Examination (PSE), the Brief Psychiatric Rating Scale (BPRS), and a brief Psychiatric Assessment Scale (PAS). Bilingual Hispanic clinicians were formally trained to administer these instruments. Key relatives of the patients were interviewed by Spanish-speaking researchers trained to administer and reliably rate the Camberwell Family Interview (CFI) schedule (Vaughn & Leff, 1976). Several other procedures were also completed with relatives and patients; however, this report will focus only on expressed emotion and medication compliance in relation to clinical outcome at 9 months post-hospital discharge.

The Rating of Outcome

The ratings for clinical outcome were made on the basis of integration of clinical information from records at treatment facilities, monthly telephone log sheets, notes from household return visits by CFI interviewers, and initial and final PSE, BPRS, and PAS ratings. All the available information for a case was reviewed by bilingual clinical psychologists who then made a final clinical status rating. These raters did not categorize outcome for patients they themselves had interviewed and were also "blind" to the EE ratings. Outcome ratings were made employing the following three categories:

1) *Sustained Remission*. This rating required a continuous absence of positive psychotic symptoms beginning no later than three months after index hospitalization and extending at least to the time of 9-month followup.

2) *Psychotic Relapse*. This rating was made only in cases in which subjects had entered a prior period of clear remission as just described, followed by decompensation.

3) *Sustained Psychoticism*. This category was defined as a failure of positive psychotic symptoms to remit for a continuous period of at least three months, beginning within three months after discharge from index hospitalization.

Reliability checks of the outcome categories were made by randomly selecting 16 cases for independent "blind" ratings by the 2 rating psychologists. An overall agreement of 88 percent (14/16) was obtained. Subsequent to careful review and discussion of the first 6 cases rated for outcome, 100 percent agreement was reached for the final 10 of these cases.

Results

Tables 1 and 2 provide basic sociodemographic and clinical characteristics for the 70 patients and the 109 key relatives assessed for their "expressed emotion." The degree of acculturation of patients and key relatives was ascertained through use of an Acculturation Rating Scale for Mexican-Americans designed by Cuellar, Harris, and Jasso (1980). As Tables 1 and 2 indicate, both key relatives and patients were relatively unacculturated. The five-point scale ranges from one ("wholly Mexican") to five ("wholly Anglo-American") in cultural orientation. The scale is based upon domains of language use, ethnic identity, and cultural participation. The majority of the patients and key

Totals	109	100.0

The household EE ratings for the Mexican-American sample are presented in Table 3, as are results from the British and Anglo-American studies. (The presence of only one high EE relative will result in the household designation of "high.") This cross-cultural view of expressed emotion illustrates that the Mexican-American households were lowest in criticism, hostility, and over-involvement concerning their ill relatives. The finding of significant cross-cultural differences in levels of expressed emotion among Mexican-American families compared to Anglo-American households constitutes one of the major findings of the study. As can be noted in Table 3, there were no significant differences between the Mexican-American and British samples in this regard. While these scores may be similar, it should be evident that the nature and meaning of family expressed emotion is culturally specific. (This subject will be discussed more fully in a forthcoming publication.) Individual profiles obtained for the key relatives are illustrated in Table 4, revealing that high levels of expressed emotion characterize only a little more than one-fourth (28 percent) of the Mexican-American relatives.

Clinical Outcome

From the original sample of 70 patients, 16 cases were lost to final followup for a variety of reasons: several patients and their families ($N = 7$) moved and left no indication of how they could be located; several ($N = 5$) were continuously hospitalized in a state hospital on a long-term basis subsequent to initial recruitment and were resident too short a time in their family households to be rated. One family refused further contact with the study; one patient left her household after a short stay at home to live with other relatives; one (the only) key relative moved out of a patient's household; and one patient died. The 54 cases for whom full followup data were collected were followed for 9 months after hospital discharge and resided continuously in the household from which the EE ratings were obtained. There was only one statistically significant difference in the clinical, sociodemographic, and expressed emotion characteristics of the 54 patients for whom complete data were available compared with the 16 patients lost to followup.[1]

Results for the 9-month outcomes for the final sample of 54 cases are presented in Table 5. Table 6 illustrates the total schizo-

---

[1] Only one household characteristic significantly differed. Among the group for whom full followup data were available, patients were more likely to be living with parents than with spouses or siblings ($p = .01$). This difference may reflect a greater stability in parental households as compared with others included in the study.

TABLE 5. Outcome Status at 9-Month Followup of 54 Schizophrenic Patients ($N = 54$).

Outcome Category	N	%
Stable Remission	27	50.0

Sustained Psychosis	10	18.5
Totals	54	100.0

phrenic symptom scores derived from PSE ratings for each outcome category at the time of initial and followup assessments. While all patients displayed a decrease in the severity of symptomatology, it is clear that patients in the sustained remission group demonstrated the most significant change ($p < .001$).

Relapse and Expressed Emotion

The relapse rates were analyzed for those patients who experienced some period of non-psychotic stabilization. A total of 10 patients (5 from low EE families), who remained continuously psychotic (and therefore could not "relapse"), were excluded from these analyses, as were such cases in the Anglo-American study. Results for the remaining 44 cases are presented in Table 7. As illustrated, remitted patients from low EE households relapsed at a significantly lower rate than did those from high EE households. This result replicates previous findings (Brown, Birley, & Wing, 1972; Vaughn & Leff, 1976; Vaughn et al., 1984) on the relationship of EE and schizophrenic relapse for the Mexican-American sample.

It is also important to note that in the Mexican-American sample, as in the Anglo-American study, total PSE schizophrenic symptom scores were not significantly correlated with EE ratings (household or individual profiles). Therefore, it appears that expressed emotion cannot be explained simply as family members' responses to varying levels in the severity of schizophrenic symptomatology.

TABLE 6. PSE* Schizophrenic Mean Symptom Scores for Each Outcome Group.

Outcome Group	Initial	Final	Diff	t

High	7 (41%)	10 (59%)	17

$p = .031$ by Fisher's Exact Test.

Medication Compliance, Expressed Emotion, and Clinical Outcome

Medication compliance was rated according to the criteria employed in the British and Anglo-American studies. A patient was considered to have adhered to neuroleptic medication regimens "regularly" if he or she had been taking drugs continuously during the 9-month followup period with no time of up to 4 consecutive weeks without medication. For those cases in which 4 consecutive weeks had passed without taking prescribed medications, medication use was rated as "irregular." Twenty-four (56%) of the 43 available cases (one of the 44 cases could not be confidently rated for medication compliance) were rated "regular" in use of medication; 19 (44%) were considered "irregular."

Table 8 presents the varying contributions of medication and expressed emotion for outcome. As indicated, there is no confounding of the effects of these two variables. Moreover, this analysis shows the effect of EE on outcome as stronger than that of medication. The most favorable clinical outcome was observed for patients who resided in low EE homes and regularly took anti-psychotic medications; 88 percent of these patients experienced sustained remissions.

It should be pointed out that all 10 (100%) of the patients in the "sustained psychoticism" outcome category (excluded from the relapse analyses) were rated as "irregular" in their compliance with medication. A separate discriminant function analysis of all three outcome categories (including sustained psychoticism) revealed medication compliance to be predictive of outcome for patients

TABLE 8. Relationship of Families' EE Score, Patients' Medication Compliance and Clinical Outcome (Total Patient Sample, $N = 43^*$).

	Medication Compliance			
	Irregular		Regular	
Families' EE	Sustained Remission	Psychotic Relapse	Sustained Remission	Psychotic Relapse
Low	6 (60%)	4 (40%)	14 (88%)	2 (12%)
High	3 (33%)	6 (67%)	4 (50%)	4 (50%)

From Log-Linear Analysis:

Effect	χ^2	*d.f.*	*p*
EE × Medication	0.08	1	(n.s.)
EE × Relapse	4.85	1	0.028
Medication × Relapse	2.70	1	(n.s.)

$^*N = 43$. Data on medication compliance missing for one patient.

in states of sustained psychosis ($p = .002$) and stable remission ($p = .004$), but non-significant ($p = .70$) among those patients who remitted and subsequently relapsed.

Summary and Conclusion

The basic findings of the study can be summarized as follows: 1) Expressed emotion is significantly lower among Mexican-Americans than Anglo-Americans. 2) Expressed emotion significantly predicted schizophrenic outcome among Mexican-Americans, as for British and Anglo-American samples. 3) The expressed emotion index appears to be independent of patient morbidity. 4) For those patients who experienced a period of remission during the 9 months following hospitalization for a psychotic episode, expressed emotion appears to have a greater predictive utility than does medication compliance; moreover, there is no confounding of the effects of these two variables. 5) Analyses of outcome for patients in either sustained psychosis or stable remission revealed medication to be significantly related to clinical outcome. 6) The best clinical outcome is observed when patients resided in low EE home environments and regularly adhered to maintenance pharmacotherapy.

The finding that "expressed emotion" significantly predicts the course of schizophrenic illness for Mexican-American, Anglo-American, and British patients requires explanation. It may be that the expression of angry or hostile affects in family settings constitutes a highly stressful situation for patients across a range of diverse sociocultural contexts, and that such environments often portend a poor course for schizophrenic illness. While this relationship has held up for culturally distinctive groups, it is important to point out that the nature and meaning of "expressed emotion" among these three groups varies in qualitatively important ways. However, while the symbolic and emotional meaning of family interactions are culturally and individually specific, a patient's general perception of an absence of love, acceptance, or support may be similarly experienced as distressing. Such perceptions on the part of the patient, along with the daily difficulties inherent in coping with a home environment marked by asperity and tension, may prove inimical to sustained recovery. (This point, however, deserves discussion beyond the scope of the current report.)

It is also critical to note a host of other life stressors that are likely to also impact upon patterns of relapse among Mexican-American patients, including such factors as immigrant, minority, and lower socioeconomic status; a severe lack of culturally and linguistically appropriate mental health facilities; and continuing prejudice and discrimination. It is our hope that further analyses and research results from the COSAMA Project will contribute toward the formulation of culturally meaningful psychosocial and pharmacotherapeutic interventions for Hispanic-American patients and their families.

Expressed Emotion, Affective Style, Lithium Compliance, and Relapse in Recent Onset Mania[1]

David J. Miklowitz, Ph.D., Michael J. Goldstein, Ph.D., Keith H. Nuechterlein, Ph.D., Karen S. Snyder, M.A., and Jeri A. Doane, Ph.D.[2]

Two family communication factors have been identified that appear to have predictive utility for the course of schizophrenia: expressed emotion (EE), a measure of the degree to which a key relative (usually a parent) holds highly critical, hostile, and/or emotionally overinvolved *attitudes* toward the patient, and affective style (AS), a measure of the emotional-verbal *behavior* of relatives in direct interaction with the patient. Schizophrenic patients from families judged to be high EE are at approximately a fourfold greater risk for relapse in the 9 months following hospital discharge than are patients from families rated low EE (Brown et al., 1972; Vaughn & Leff, 1976: Vaughn et al., 1984). Similarly, schizophrenic patients from families rated as negative AS during the postdischarge period are at far greater risk for relapse in the first 9 months of followup than are patients from families who demonstrate AS behaviors that are emotionally benign (Doane et al., 1985). High-EE intrafamilial attitudes and negative-AS behaviors, while often coexisting in the same family, are not isomorphic to one another (Miklowitz et al., 1984).

There has been interest in recent years in studying the applicability of these family measures to other psychiatric populations. In their original study of schizophrenic patients and their parents, Vaughn & Leff (1976) included a comparison group of nonpsychotic depressed patients and their spouses, and found that high-EE attitudes in spouses were predictive of depressive relapse in the patient. This finding was later replicated by Hooley et al. (in press). However, the predictive utility of EE attitudes has never been studied in psychotic populations other than schizophrenia, and the above-mentioned replication studies were based on spousal, rather than parental families. Furthermore, the predictive utility of negative intrafamilial AS behaviors has never been studied in a nonschizophrenic or schizophrenic spectrum population.

The present study was designed to test the applicability of intrafamilial EE and AS to the parental families of patients with another psychotic illness, bipolar affective disorder. Bipolar illness, like schizophrenia, follows a relapse-remission course, and can be quite disruptive to the family environment. Further, it is estimated that a large proportion of bipolar patients (i.e., 47%) require rehospitalization or show exacerbations during a 1-year period despite following recommended lithium regimens (O'Connell & Mayo, 1981). It was hypothesized that the emotional climate of the family to which a recently episodic bipolar patient returns following hospitalization may be one factor accounting for a proportion of the variability in patient illness outcome.

Method

Subjects

Patients in this sample were 24 recently episodic bipolar–manic patients recruited from inpatient wards at the UCLA Neuropsychiatric Hospital in Los Angeles. Patients were interviewed by a trained research staff member using an extended version of the Present

State Examination (PSE; Wing, Cooper, & Sartorius, 1974), and were diagnosed using the Research Diagnostic Criteria (RDC; Spitzer et al., 1978). Patients met RDC criteria for manic episode (n = 13) or schizoaffective, mainly affective, manic episode (n = 11). Diagnoses were later confirmed by an independent clinician on the basis of case summaries describing the patient's current episode. Exclusionary selection criteria for the sample are described in detail elsewhere (Nuechterlein, 1982).

The mean age of the 24 patients (13 male, 11 female) was 21.45. Age of onset of bipolar illness tended to be early (mean = 19.88 years), and the average duration of illness since onset was 9.42 months. The sample was primarily Caucasian and of high socioeconomic status. Nine patients were living with or in significant contact with one parent, 14 had two parents, and 1 was living with a spouse.

Procedure

Expressed emotion. Patients were first interviewed and diagnosed during the inpatient phase. If a patient met the diagnostic and exclusionary criteria, his/her relatives were administered the Camberwell Family Interview (CFI; Vaughn & Leff, 1976) by a trained staff member. The CFI is a 1½-hour interview focusing on the patient's most recent psychiatric episode and its impact on the family environment. Following the interview, the number of *critical* comments made by the relative, or statements of dislike or resentment regarding the patient with accompanying voice tone, were counted by a trained judge on the basis of audiotapes of the interview. In addition, ratings were made of the degree to which the relative showed evidence of *emotional overinvolvement*, or markedly overconcerned, self-sacrificing, overprotective attitudes toward the patient. Emotional-overinvolvement ratings were based on a 0 (absent) to 5 (high) scale. Camberwell judges had attained minimum interrater reliability coefficients of .80 on these two EE subscales prior to participation in the present study, and were blind as to any other information about the patient and his/her family.

Relatives were rated high EE if they made at least 6 criticisms and/or were rated as moderately high (4) or higher on emotional overinvolvement. Relatives who did not meet these criteria were classified as low EE. *Families* were rated high EE if one or more key relatives were so rated.

Affective style. Approximately 3 weeks after the patient's hospital discharge, a 2-hour family-assessment session was conducted with each patient and his/her parents or spouse. Family members were first interviewed about their current family environment, and conflict issues within the family were identified. The family was then brought together and asked to discuss two such issues for 10 minutes each while the experimenter was out of the room. Typed transcripts were generated from audiotapes of these interactions, and the transcripts were coded on dimensions of affective style (AS; Doane et al., 1985).

For the present study, relative-to-patient statements during the interactions were coded along two major dimensions: (1) critical statements, which could be of a benign, situational type (e.g., "You have a bad attitude about school, Tom"), a harsh, severely negative type ("You have an arrogant, stupid attitude"), or of a guilt-inducing type ("You are making life miserable for us"); (2) neutral-intrusive statements, which imply that the relative has a special knowledge about the patient's attitudes or feeling states, beyond what the patient has stated explicitly (e.g., "You always feel guilty when you're around Dad"). Families were rated as negative AS if at least one relative made (a) one or more severely critical or guilt-inducing statements during either 10-minute interaction, or (b) 6 or more neutral-intrusive statements (Doane et al., 1985).

Transcripts were rated by one of two raters who were blind to the other family assessment and patient outcome data. Interrater reliability for AS codes was .78 (kappa statistic).

Patient followup. Patients were followed for a 9-month period following discharge. Every 3 months, the patient was interviewed on a face-to-face basis and was rated on an extended version of the Brief Psychiatric Rating Scale (BPRS; Overall & Gorham, 1962; Nuechterlein, 1982). In addition, an abbreviated version of the scale was administered on a monthly basis over the telephone. The BPRS interviewer had completed a workshop on the administration and scoring of the scale, and interrater reliability, calculated across each subscale, averaged .80. In addition, the rater was blind to the baseline family assessment data.

Patients were judged to have relapsed (total $n = 14$) if they showed a significant clinical exacerbation (i.e., a rise to BPRS scale point 5, 6, or 7) following a minimum 1-month period of remission (i.e., all BPRS scales at 3 or below) or near remission on at least one of 10 subscales judged to be relevant to manic or depressive relapse. Patients were classified as nonrelapsers ($n = 7$) if they retained a state of clinical remission or near remission for the majority of the 9-month followup period, with no exacerbations. Patients were judged to be clinically unchanged if they retained a state of moderately severe, severe, or extremely severe (i.e., scale points 5, 6, or 7) symptomatology for at least 6 of the 9 months of followup ($n = 2$; Nuechterlein, Miklowitz, & Ventura, 1985).

Assessments of the patients' level of medication (usually lithium) compliance were also conducted every 3 months. Ratings of compliance were based on self-report information from the patient, data obtained from key relatives and the patient's physician, and serum lithium levels (Cochran, 1982). Patients were judged to be noncompliant (total $n = 16$) if they demonstrated at least one 3-month period in which they were missing at least one dosage per week. More typically, these patients were ingesting less than 50 percent of their prescribed medication. Compliant patients were those who missed a maximum of one or two dosages per month throughout the 9-month followup period (total $n = 7$). Interrater agreement on ratings of compliance vs. noncompliance was .92 (kappa statistic).

Results

The first question posed by the current study concerned the relative utility of intrafamilial affective attitudes (EE) and behavior (AS) in predicting the longitudinal course of manic disorder. Results are presented in Table 1. For these analyses, patients with relapsing and unchanged outcomes were combined due to the small number of subjects in the unchanged cell. All χ^2values were calculated using the likelihood ratio method.

TABLE 1. Family Expressed Emotion Status and Affective Style Profiles as Predictors of 9-Month Clinical Outcome.

Family EE Status	No Relapse	Relapse/Unchanged
Low EE	6	7
High EE	1	9

$\chi^2 (1) = 3.82, p = .05$

Family AS Profile	No Relapse	Relapse/Unchanged
Benign AS	5	6
Negative AS	1	10

$\chi^2 (2)=3.92, p < .05.$

Conjoint Prediction Family Pattern	No Relapse	Relapse/Unchanged
Low EE/Benign AS	5	1
Negative on One	0	11
Negative on Both	1	4

$\chi^2 (2) = 15.37, p < .0005.$

Note: Outcome data were unavailable for one patient who refused the longitudinal followup. In addition, one family consented to the Camberwell Family Interview (EE) procedure but declined to participate in the direct interaction (AS) exercise.

High-EE attitudes in relatives were moderately associated with poor clinical outcomes, with 90 percent of patients from high-EE homes demonstrating recurrences at followup ($p = .05$). Similarly, as indicated in Table 1, negative family AS profiles were moderately associated with poor outcomes ($p < .05$).

The finding that family EE status and AS profiles were unrelated in this sample ($p > .10$) suggested that family affective attitudes and behavior might be usefully combined and treated as conjoint predictors of patient outcome. As indicated at the bottom of Table 1, this combination of predictive factors accurately identified 91 percent of the good and poor clinical outcomes in this sample ($p < .0005$). This improved level of prediction occurred because the two family factors appeared to be associated with different types of patient outcome: High-EE intrafamilial attitudes were most common in cases where the patient achieved a state of full remission following discharge and then evidenced a significant clinical relapse or exacerbation, whereas patients from negative-AS homes either (a) showed high levels of persisting symptomatology throughout followup, and then manifested a clinical exacerbation on top of this ongoing residual illness, or (b) remained unchanged and highly symptomatic throughout followup.

Medication compliance was not in itself a significant predictor of clinical outcome in this sample [χ^2 (1) = .71, $p > .10$], nor was this variable associated with level of intrafamilial EE or AS (ps $> .10$). However, both EE and AS interacted to some degree with medication compliance in predicting manic outcome (Table 2). Patients from high-EE or negative-AS homes tended to relapse regardless of whether they were compliant with their medication regimens. However, patients from low-EE or benign-AS homes tended to have positive outcomes only when they were medically compliant. Those who were noncompliant demonstrated rates of relapse similar to those noted in the high-EE and negative-AS cells.

TABLE 2. Expressed Emotion, Affective Style, Medication Compliance, and Patient Illness Outcome.

Expressed Emotion and Medication Compliance	No Relapse	Relapse/ Unchanged
Low EE		
Compliant	3	1
Noncompliant	3	6
High EE		
Compliant	0	3
Noncompliant	1	6

χ^2 (3) = 6.57, $p = .09$.

Affective Style and Medication Compliance	No Relapse	Relapse/ Unchanged
Benign AS		
Compliant	3	1
Noncompliant	2	5
Negative AS		
Compliant	0	3
Noncompliant	1	7

χ^2 (3) = 6.88, $p < .08$.

Discussion

The present study tested the utility of two measures of family affective communication, intrafamilial expressed emotion and affective style, in predicting the course of recent onset mania. Both EE and AS were individually, though moderately, predictive of 9-month clinical outcome in this sample. Results are consistent with those of Doane et al. (1985) and Vaughn & Leff (1976) in suggesting that the intrafamilial environment to which a psychiatrically disturbed patient returns following hospitalization is an important influence on the subsequent course of the disorder.

Prediction of outcome was optimal when intrafamilial EE and AS were combined and treated as conjoint predictors: 91 percent of the clinical outcomes were accurately identified in this manner. This level of prediction was achieved due to the finding that EE and AS were associated with different types of clinical outcome at followup. Therefore, in a bipolar sample, it may be necessary to have information on both family attitudes and actual interactional behavior in order to confidently predict the subsequent course of the patient's illness.

Medication compliance was not by itself significantly associated with illness course in this sample, but did tend to mediate the relations between family factors and 9-month clinical outcome. Specifically, when the family environment to which the patient returned following hospitalization was negative, patients were at high risk for a poor clinical outcome regardless of whether they were medically compliant. However, a neutral or benign family environment was associated with a good clinical outcome only when the patient consistently adhered to his/her medication regimen. These findings contrast to some degree with those of Vaughn & Leff (1976), who reported that, in a schizophrenic sample, medication compliance was to some degree a protective factor against relapse for patients from high-EE homes, whereas patients from low-EE homes had positive outcomes regardless of their medication-taking habits. The present findings indicate that some manic patients, unlike schizophrenics, may benefit from a consistent medication regimen only when the family environment is affectively benign.

Due to the small number of subjects utilized in the present study, the findings should be viewed as tentative and in need of replication. However, the results do suggest that the affective climate of the family following hospitalization may be an important factor contributing to the subsequent course of bipolar disorder. Further, treatment of the family as a unit during the outpatient phase may be a useful adjunct to medication management for these patients.

Expressed Emotion, Fixed-Dose Fluphenazine Decanoate Maintenance, and Relapse in Recent-Onset Schizophrenia[1]

Keith H. Nuechterlein, Ph.D.,[2] Karen S. Snyder, M.A.,[2] Michael E. Dawson, Ph.D.,[2] Sandra Rappe, M.S.W.,[2] Michael Gitlin, M.D.,[2] And David Fogelson, M.D.[2]

The presence of high levels of critical comments, hostility, or emotional overinvolvement, as expressed by family members during the Camberwell Family Interview (CFI; Brown & Rutter, 1966; Rutter & Brown, 1966; Vaughn & Leff, 1976b), has been shown to be highly predictive of psychotic relapse during the 9, 12, or 24 months following hospital discharge after an acute schizophrenic episode (Brown et al., 1962; Brown et al., 1972; Leff & Vaughn, 1981; Vaughn & Leff, 1976a; Vaughn et al., 1984). The term "expressed emotion" is used to describe the set of CFI measures that quantify the attitudes, feelings, and behaviors concerning the patient that are expressed or reported by a relative. Although there are numerous scales of expressed emotion, only the scales involving 1) the number of critical comments, 2) the presence of hostility, and 3) the level of emotional overinvolvement have been predictive of psychotic relapse (Brown et al., 1972; Vaughn et al., 1984).

In the CFI scoring procedure, a critical comment is a statement of unambiguous dislike, disapproval, or resentment of the patient's actions, attitudes, or feelings. Hostility is rated as present based on remarks that spell out an all-encompassing rejecting attitude toward the patient and/or generalized negative comments about the person himself or herself rather than about selected behaviors or characteristics. In practice, hostility is rarely found in interviews in which critical comments are not numerous. For the emotional overinvolvement rating, the most important information is the amount and degree of self-sacrificing and devoted behavior or overprotective behavior demonstrated by the relative. Expression of a high number of critical comments, hostility, or a high level of emotional overinvolvement by a family member in relationship to the patient has come to be summarized as "high expressed emotion" (EE)* and has been associated with a 3- to 8-fold increase in the rate of psychotic relapse.

Although the studies of EE conducted by Brown et al. (1972) and Vaughn and Leff (1976a) in Great Britain and by Vaughn et al. (1984) in California reported patients' outpatient medication adherence, they did not involve experimental control for medication effects. Examination of data within these initial studies indicated that patients who were maintained on regular antipsychotic medication had lower relapse rates than those who had irregular or no antipsychotic maintenance medication (Vaughn & Leff, 1976a; Vaughn et al., 1984), but suggested that familial EE had a predictive role that was not statistically accounted for by the regular/irregular medication dichotomy (Vaughn et al., 1984). The reduction of relapse rate in chronic schizophrenia by maintenance antipsychotic medication is well established (e.g., Hogarty, Goldberg, & the Collaborative Study Group, 1973; Leff & Wing, 1971; Rifkin, Quitkin, Rabiner, & Klein, 1977). Because the earlier EE studies did not experimentally control medication administration or dosage, the varying medication practices of the treating physicians, unreliable reporting of compliance with oral medications, and patient self-selection for regular/irregular medication may have had unknown effects on the results. The present study examines the predictive role of familial EE for psychotic relapse under conditions in which patients are administered a standardized dosage of antipsychotic medication in a reliable injectable fashion and are followed in a common manner in the same aftercare clinic.

*This categorization of a family member as high vs. low in "expressed emotion" is somewhat a misnomer, as it is based only on negative attitudes and extreme overconcern. This misnomer has occurred because other initial dimensions of expressed emotion, the expression of warmth and positive remarks, were found to bear no linear relationship to the patient's outcome (Brown et al., 1972; Leff & Vaughn, 1985) and have, therefore, not been used in the summarizing dichotomy for familial level of expressed emotion.

A second major feature of the conditions of the present study involves the restriction of the sample to schizophrenic patients with a recent onset of psychosis. The earlier studies included patients who varied widely in chronicity, ranging from many years of illness to a smaller number who were experiencing their first episode. Increased experience with a schizophrenic patient's repeated episodes might have elicited increased critical comments, hostility, or emotional overinvolvement in family members, thereby leading to a predictive relationship between these family attitudes and higher relapse rates that did not involve any causal role for the family attitudes. Restriction of the present sample to patients who had experienced their first psychotic episode in the previous 2 years allows an opportunity for the predictive role of familial EE to be examined in a situation in which the attitudes of family members are not confounded with experience of established chronicity of illness.

Another important feature of the current study is the use of objective, quantitative criteria for psychotic relapse based on Brief Psychiatric Rating Scale (BPRS; Overall & Gorham, 1962) evaluations completed every 2 weeks. This intensive, ongoing monitoring of symptomatology by reliable, carefully trained raters had allowed more precise criteria for psychotic relapse to be developed, thereby taking one additional step in the progressive improvements in psychotic relapse criteria that had characterized the Brown et al. (1972), Vaughn and Leff (1976a), and Vaughn et al. (1984) investigations. This study continues the primary focus on return or exacerbation of psychotic symptoms. Thus, as in the Brown et al. (1972), Vaughn and Leff (1976a), and Vaughn et al. (1984) studies, psychotic relapse is not mixed with nonpsychotic forms of symptomatic excerbation and with rehospitalizations based on breakdowns of social support systems that do not involve significant exacerbation of psychotic symptoms.

The data reported here summarize the EE results from analyses for the first 30 patients to finish a 1-year, fixed-dose, fluphenazine (Prolixin) protocol within an ongoing project, Developmental Processes in Schizophrenic Disorders (Principal Investigator: Keith H. Nuechterlein, Ph.D.), in which the predictive roles of several key social, psychological, and biological factors in the early course of schizophrenic disorders are being evaluated.

Methods

Subjects

The schizophrenic patients were selected from the Los Angeles metropolitan region during an index hospitalization at one of four public hospitals (UCLA Neuropsychiatric Institute & Hospital, Camarillo State Hospital, Harbor/UCLA Medical Center, Olive View Medical Center) or, in a few cases, at one of the local private hospitals. These subjects were required to have the following characteristics: 1) a diagnosis of schizophrenia or of schizoaffective disorder, mainly schizophrenic, by Research Diagnostic Criteria (Spitzer, Endicott, & Robins, 1978), determined by trained research personnel based on an expanded version of the Present State Examination (PSE; Wing et al., 1974) administered to the patient and consideration of any additional data gathered from relatives; 2) a recent onset of major psychosis lasting at least 2 weeks (first psychotic episode not longer than

2 years before project contact); 3) age between 16 and 45 years; and 4) Caucasian, acculturated Asian, or acculturated Hispanic in ethnic background. Subjects with any of the following were excluded: 1) evidence of an organic central nervous system disorder (e.g., epilepsy, traumatic brain injury, infectious or toxic cerebrovascular disease); 2) significant and habitual drug or alcohol abuse in the 6 months prior to the current episode, or past drug or alcohol abuse that clouded the diagnostic picture; or 3) mental retardation (premorbid IQ less than 70).

To be included in these analyses, patients needed to be maintained in the medication protocol for 1 year or until they relapsed. Three patients who relapsed after discontinuation of their antipsychotic medication were eliminated from analyses. To qualify for inclusion in the EE portion of the larger project, patients were required to have been in contact at least weekly with a family member during at least 1 of the 3 months prior to the index hospitalization. Twenty-seven of the initial 30 schizophrenic patients who finished the fixed-dosage medication protocol met this criterion. One additional patient who was maintained on oral fluphenazine due to refusal of injections was excluded from analyses for this report of patients maintained on fluphenazine decanoate. The 26 participating schizophrenic patients (20 male, 6 female) had a mean study-entry age of 22.6 years (SD = 3.4; range = 19 to 32 years). The mean educational level was 12.1 years (SD = 1.9, range = 9 to 16 years). Twenty-three of the patients were Caucasian, two were acculturated Hispanic, and one was acculturated Asian. For 22 of 26 patients, the index period was the first psychotic episode, and for 19 of 26 patients, the index hospitalization was the first psychiatric hospitalization.

Procedure

Expressed emotion. The family members who had significant contact with the patient were administered the abbreviated version of the Camberwell Family Interview (CFI; Vaughn & Leff, 1976b) within 1 month of the patient's hospital admission. The CFI is a standardized, semi-structured interview that focuses on the onset and development of the present illness episode and its impact on family life in the 3 months before hospitalization. Spontaneous expressions of feelings and self-reports of emotions are noted, with emphasis on the former. The entire interview is tape-recorded for later scoring.

Ratings of critical comments, hostility, and emotional overinvolvement were completed by the interviewers shortly after the CFI according to procedures established in the original British work. Interviewer/raters were trained to reliability by Christine E. Vaughn, Ph.D., and Karen S. Snyder, M.A., and were required to achieve interrater reliability with the criterion judges of at least $r = .80$ (Pearson correlation) prior to study participation. Randomly selected interviews were also co-rated by one of the authors (K.S.S.) and other trained raters to ensure maintenance of high interrater reliability.

The family environment was rated as high in EE if any family member made six or more critical comments, was rated as high or marked 4 or 5 on emotional overinvolvement, and/or was rated as showing hostility. In the absence of these features, it was rated low in EE.

Outpatient treatment. All of the patients were seen regularly at the Aftercare Clinic of the UCLA Mental Health Clinical Research Center (MHCRC) for the Study of Schizophrenia, which is located at the UCLA Neuropsychiatric Institute. Patients were placed on a standardized dosage of fluphenazine decanoate, 12.5 mg every 2 weeks, as soon as their clinical state could be stabilized during the first 2 to 3 months of outpatient treatment. (One patient who developed intolerable side effects on this dosage was maintained on a fixed dosage of 10 mg every 2 weeks.) Two psychiatrists (M.G. and D.F.) on the research team maintained the medication protocol. Individual case management and supportive therapy were provided by clinic therapists. Clinic staff involved in a patient's treatment were blind to the EE level of the family.

The 1-year period of outcome evaluation began when a patient completed a battery of information-processing, psychophysiological, and personality measures, which occurred 1 month after the standardized medication was initiated.

Evaluation of outpatient outcome. The individual case manager completed a rating of patient symptomatology every 2 weeks, using an expanded form of the BPRS that was developed by David Lukoff, Ph.D., Keith H. Nuechterlein, Ph.D., and Joseph Ventura, M.A. This BPRS version includes behavioral anchors and a structured interview format to standardize rating levels. Before rating the study patients, the BPRS raters were required to complete a training program that included rating a set of audiotaped interviews as well as conducting and rating their own interviews. A median interrater reliability (intraclass correlation coefficient) of at least .80 for all subscales was required of each rater. Median interrater reliabilities across raters on the three key symptoms used to evaluate psychotic relapse, Unusual Thought Content, Hallucinatory Behavior, and Conceptual Disorganization, were .93, .97, and .73 (intraclass correlation coefficients), respectively.

A nine-category system for evaluating psychotic relapse was modeled after the system used by Vaughn et al. (1984), but was keyed to the BPRS rather than the Psychiatric Assessment Scale (Krawiecka et al., 1977) and PSE to take advantage of the more differentiated seven-point scales and to allow easier application by the large number of investigators who are familiar with the BPRS. The category definitions are based on initial and subsequent outpatient symptomatology on the three psychotic scales (Nuechterlein et al., 1985). Three subtypes of psychotic relapse are (initial status—subsequent status): Remission—Relapse; Remission—Significant Exacerbation; and Persisting Symptoms—Significant Exacerbation. Five subtypes of outcomes without relapse are: Remission—Remission; Persisting Symptoms—Remission; High Persisting Symptoms—Improvement; Persisting Symptoms—Persisting Symptoms; and Remission—Mild Exacerbation. Finally, a category for patients who never improve sufficiently to allow room for a Relapse or Significant Exacerbation is called High Persisting Symptoms—High Persisting Symptoms.

Space does not allow the details of the nine-category outcome system to be described here. However, the criteria for the first two psychotic relapse sub-categories can be summarized as requiring an increase to a rating of 6 (severe) or 7 (extremely severe) for Relapse or a rating of 5 (moderately severe) for Significant Exacerbation on the Unusual Thought Content, Hallucinatory Behavior, or Conceptual Disorganization scales, preceded by an initial Remission period [at least 1 month of BPRS ratings on the three psychosis scales of 3 (mild) or below]. The third subcategory of psychotic relapse concerns patients who show Persistent Symptoms [continuing ratings of 4 (moderate) or above on at least one of the psychotic scales]. To be classified as having a Significant Exacerbation, these patients must show an increase to a rating of 6 or 7 that involves a 2-point change on one of the psychotic scales. Patients are classified as nonrelapsers if they show neither Relapse nor Significant Exacerbation, unless their psychotic symptoms persist at such a high level as to preclude these states. Patients are classified as showing Unchanged High Persisting Symptoms if they maintain a rating of 5 or above on any of the psychotic scales for at least two-thirds of the followup period and never meet criteria for Improvement (ratings of 4 or less on psychotic scales sustained over 3 months).

Two independent judges placed each of the patients into one of the nine categories of outcome based on the BPRS scores, without knowledge of the EE status of the family environment. Interrater agreement on placement of cases into the nine categories was 93 percent, and agreement for the three groupings of relapse, no relapse, and unchanged high persisting symptoms categories was 100 percent. In two cases, these two judges disagreed on the subcategory of relapse to be assigned. For these cases, a third independent judge rated outcome and a consensus rating was used.

Results

Table 1 presents the distribution of 1-year outcomes for the 26 patients available for these analyses of the predictive value of familial expressed emotion under controlled, fixed-dose fluphenazine decanoate medication conditions. The overall 1-year relapse rate is 27 percent (7 of 26), which is within

TABLE 1. 1-Year Outcomes of Schizophrenic Patients Maintained on Standardized Dosage of Fluphenazine Decanoate

Initial Status	Later Status	*n*
Relapse categories		
Remission	Relapse	4
Remission	Signif. Exacerbation	3
Persisting Symptoms	Signif. Exacerbation	0
No-relapse categories		
Remission	Remission	16
Persisting Symptoms	Remission	2
High Persisting Symptoms	Improvement	0
Persisting Symptoms	Persisting Symptoms	0
Remission	Mild Exacerbation	1
Unchanged high persisting symptoms		
High Persisting Symptoms	High Persisting Symptoms	0

the expected range based on past studies of schizophrenic patients maintained on antipsychotic medication (Hogarty et al., 1973; Hogarty et al., 1979; Leff & Wing, 1971; Davis, 1985).

As shown in Table 2, the 1-year relapse rate for patients from high EE environments was 37 percent, whereas none of the patients from low EE environments relapsed. Thus, for the first 26 patients who have finished the 1-year, standardized fluphenazine decanoate period in this ongoing study, high familial EE already predicts psychotic relapse at a statistically significant level (likelihood ratio chi-square = 5.28, $p < .03$; Hays, 1973). The correlation (phi coefficient) between EE level and psychotic relapse is .37. [If the patient maintained on oral fluphenazine is included, the relapse rate for patients from high EE environments is 40 percent (8 of 27), which strengthens further the differential relapse rate for patients in high vs. low EE environments.]

To examine the possibility that relatives' high EE may be partially a reaction to experience with duration of the patient's schizophrenic illness or psychiatric hospitalization, even within the period preceding chronic schizophrenia [by the American Psychiatric Association's *DMS-III* (1980), the first 2 years of illness], the association of high EE with indices of illness duration was examined. In addition, the relationship of EE level to the inpatient overall severity of symptomatology (sum of the standard 18 BPRS scales) and to key demographic factors was determined. As shown in Table 3, in this sample of recent-onset schizophrenic patients, the EE level of the family was not related to the duration of the patient's illness, the duration or number of past hospitalizations, severity of inpatient overall symptomatology, patient age, patient

TABLE 2. Prediction of Psychotic Relapse From Relatives' Expressed Emotion Level Rated From CFI at the Index Hospitalization

EE of Relatives	No Relapse	Relapse	1 Yr. Relapse Rate
High (6 or more Critical Comments, Emotional Overinvolvement rating of 4 or 5, or Hostility)	12	7	37%
Low (0-5 Critical Comments; no marked Emotional Overinvolvement; and no Hostility)	7	0	0%

Note. $p < .03$, likelihood ratio χ^2.

TABLE 3. Illness Duration, Past Hospitalization, Inpatient Symptomatology Level, and Demographic Characteristics of Recent-Onset Schizophrenic Patients From Families With High vs. Low Expressed Emotion

Background Factor	High EE ($n = 19$) *M* (*SD*)	Low EE ($n = 7$) *M* (*SD*)	*t*	*p*
Total months of illness, including prodromal period	12.3 (9.9)	14.7 (5.9)	−.60	NS
Total weeks of hospitalization including index hospitalization	6.2 (3.7)	4.3 3.9)	1.14	NS
Number of previous hospitalizations	0.4 (0.8)	0.3 (0.5)	.40	NS
Inpatient BPRS total psychopathology score (18 scales)	31.9 (7.3)	33.0 (7.2)	−.34	NS
Age (years)	22.2 (2.7)	23.6 (4.9)	−.69	NS
Educational level (years)	11.9 (1.8)	12.6 (2.1)	−.81	NS
Sex	14 M, 6 F	5 M, 1 F	.45^a	NS

educational level, patient sex, or rearing-family socioeconomic status. The direction of these nonsignificant differences is as would be expected by this familial reactivity hypothesis for total duration of hospitalization, but not for total length of illness. Thus, although these relationships will need to be re-examined as the sample size increases in this ongoing project, these data offer no support for the view that family EE may be a reaction to duration of experience with the patient's illness or severity of inpatient symptomatology.

Discussion

Consistent with a vulnerability/stress model of schizophrenic psychotic relapses (Nuechterlein & Dawson, 1984), the EE level of the family environment is a significant predictor of psychotic relapse during a 1-year period of maintenance on standardized, fixed-dose fluphenazine decanoate within this ongoing study of patients who have had a recent onset of schizophrenic disorder. The presence of a significant predictive role for familial EE despite standardization and guaranteed administration of antipsychotic medication indicates that results from earlier naturalistic studies (Brown et al., 1962; Brown et al., 1972; Vaughn & Leff, 1976a; Vaughn et al., 1984) were not due to the lack of experimental control over medication administration. The 1-year relapse rates of 37 percent and 0 percent for schizophrenic patients from high EE and low EE family environments, respectively, are in the same range as would be expected from the data of Brown et al. (1972), Vaughn and Leff (1976a), and Vaughn et al. (1984) for patients who were judged to have maintained regular outpatient antipsychotic medication.

The results also indicate that the predictive role of relatives' EE is not limited to chronic schizophrenic patients, because the present sample contains only patients whose psychosis developed relatively shortly before entry into the study. In 22 of 26 cases, the index period was the first psychotic episode. Furthermore, the lack of association between relatives' EE level and length of patient's illness (including prodromal period), number of previous hospitalizations, and total length of hospitalization indicates that any residual differences in these factors among patients within this sample do not account for these familial attitudes and behaviors. Similarly, familial EE level is not associated with overall severity of inpatient symptomatology. Thus, although these data do not demonstrate directly that familial EE level has a causal influence on psychotic relapse, the predictive relationship between EE level and psychotic relapse in these data cannot be explained by an association between EE level and the patient attributes examined here.

The focus on recent-onset schizophrenic patients is shared with another current study of EE and relapse by MacMillan, Gold, Crow, Johnson and Johnstone (1986), in which statistically significant predictive effects of familial EE were found before, but not after, treatment. Duration of illness preceding admission and neuroleptic treatment following discharge were employed as covariates. The present study differs from that study in at least three important ways. First, standardized, injectable medication was employed to provide better control over medication conditions, including dosage and compliance assessment. Second, objective, quantitative criteria for psychotic relapse, applied in a uniform way based on symptom ratings by trained research staff with demonstrated interrater reliability, were used to define relapse. For their statistical analyses, MacMillan et al. (1986) defined relapse by less specific criteria of clinically judged relapse that did not demand presence of psychotic symptoms, that emphasized instead the need for hospital readmission, and that were applied by the responsible clinician in multiple participating hospitals. Finally, assessment of family EE in the present study involved all relatives with whom the patient had a significant amount of contact, rather than assessment of a single relative as was employed in all but six cases by MacMillan et al. (1986). Assessment of all key relatives should yield much more accurate determination of familial EE level, because presence of any relative who is rated above the individual scale cutoff points leads to classification of the family environment as high in EE (Leff & Vaughn, 1985). These factors may explain the stronger predictive relationship between EE level and relapse in the present study than in the MacMillan et al. (1986) report.

Molecular Aspects of Benzodiazepine Receptor Function

Paul Sweetnam, Ph.D.[1]
Peter Gallombardo, M.A.[1] and
John Tallman, Ph.D.[1]

The benzodiazepines (BDZ) are among the most widely prescribed drugs in the world today. While the clinical importance of these drugs is unquestioned, the molecular interactions underlying their effects are not fully characterized. Over the past 20 years, a number of possible mechanisms of action have been proposed (Costa & Greengard, 1975) and have been reviewed (Tallman et al.). Today with the rapid advances in biochemistry, immunology, and genetics these mechanisms will be more rigorously investigated. This should ultimately lead to an increased understanding of the molecular aspects of BDZ function.

The existence of a high affinity binding site in brain tissue for the BDZs was first documented in 1977 (Squires & Braestrup, 1977). These sites show all of the properties ascribed to other pharmacological receptors including binding that is rapid, reversible, stereospecific, and saturable. Studies in animals and man have shown a high correlation between binding ability and the potency of benzodiazepines as anxiolytics and anticonvulsants (Braestrup & Squires, 1978).

In 1978, Tallman and others (Tallman et al., 1978) showed that BDZ agonist binding is enhanced by γ-aminobutyric acid (GABA), the major inhibitory-neurotransmitter in the brain. This phenomenon of allosteric facilitation of BDZ binding, the "GABA shift," and the known electrophysiological interaction of BDZ with GABA suggests a close physical association between the BDZ and GABA receptors. It now appears likely that a supramolecular complex exists composed of the BDZ receptor, the GABA$_A$ receptor, the chloride channel, and the picrotoxin/barbiturate binding site (Figure 1) (Olsen, 1981).

BDZ agonists function within the complex to increase the efficacy of GABA, thus facilitating the inhibitory actions of GABA. This binding interaction can be inferred from the GABA shift, and has proven useful in the classification of BDZ receptor ligands. The BDZ antagonist, Ro15-1788, shows little GABA shift. Ro15-1788 is pharmacologically inactive but it can reverse the sedative and anticonvulsant actions of BDZ agonists. In contrast, inverse agonists, such as the β-carbolines, show decreased binding in the presence of GABA (Braestrup & Nielson, 1981). These compounds are anxiogenic and proconvulsant. Partial agonists, such as the

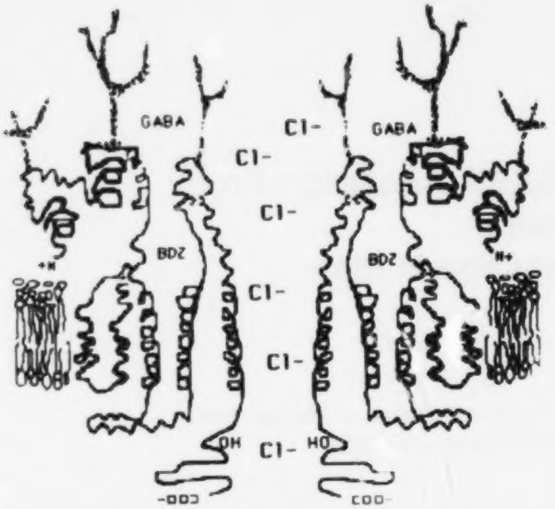

FIGURE 1. Hypothetical conformation of the GABA$_A$ complex in a neuronal cell membrane. This proposed model suggests that the GABA and benzodiazepine (BDZ) receptor proteins may form part of the chloride (Cl$^-$) anion channel. The proteins of the complex also appear to be glycosylated. These carbohydrate moieties may serve an important role in neuronal development and also alter ligand/receptor interactions.

triazolopyridazines, exhibit only a small GABA shift. These different interactions between BDZ ligand binding and GABA further support the notion that the two receptors are closely coupled.

In 1980 Mohler discovered that certain benzodiazepines with a nitro group in the 7 position could act as photoaffinity labeling reagents. Upon exposure to ultraviolet light these compounds become covalently linked to the BDZ receptor (Mohler et al., 1980). Photolabeling studies of membrane bound BDZ receptors revealed that for every receptor labeled, four agonist binding sites are converted to a very low affinity state (Thomas & Tallman, 1983). This study, and radiation inactivation studies (Braestrup, 1985) suggest that the stoichiometry of GABA and BDZ receptors is more complicated than a one to one pairing. The ability to incorporate a radiolabeled BDZ into the receptor has afforded a simple and sensitive method for monitoring biochemical manipulations and purification of the receptor.

By photolabeling membranes prior to discontinuous SDS gel electrophoresis it is possible to obtain differential labeling of proteins in various brain regions (Thomas & Tallman, 1981; Sieghart & Karobath, 1980). All investigators have demonstrated the labeling of a 50K protein; and some studies have also labeled higher molecular-weight species. The labeling of these higher molecular-weight species varies between brain regions. Attempts have been made to correlate this regional distribution with the pharmacological differences between BDZ agonists (Sieghart et al., 1983). Recently immunochemical staining using monoclonal antibodies directed against the BDZ receptor has shown a homogeneous distribution of these higher molecular-weight species (Haring et al., 1985).

Our group and others have been able to purify the BDZ receptor to near homogeneity. The receptor is initially solubilized from brain tissue with the detergent Lubrol-PX. The binding kinetics of the solubilized receptor indicate a relatively intact active site (Yousufi et al., 1979). After the solubilization the receptor is then affinity purified on an agarose matrix containing bound Ro7-1986, a BDZ agonist (Tallman & Gallager, 1979). Recovery of the receptor from the affinity gel is accomplished by a competitive ligand elution using 10^{-5}M flurazepam. High receptor yields utilizing this type of affinity elution require that an agarose bead with a long spacer arm be used for coupling. At present, the use of a 15 carbon spacer arm with a cationic charge appears to allow for the most efficient receptor recovery. The receptor after purification has a molecular weight of 50,000 and like the soluble receptor has an intact active site which can be photolabeled.

Enzymatic manipulation of the receptor has been made possible by the production of purified proteolytic and glycosidic enzymes that reliably cleave specific peptide bonds and glycosidic linkages. Subjecting photolabeled receptors to proteolytic digestion has resulted in the purification of a single limiting peptide bearing the radioligand tag (Klotz et al., 1984). Because this peptide contains the radioligand it seems probable that it also contains the agonist binding domain. Sequencing this peptide should yield valuable information about the origins of the BDZ receptor. This information could also be used to construct a genetic probe that would lead to furthering our knowledge of the molecular biology of the BDZ receptor.

The BDZ receptor, like many cell surface proteins, is heavily glycosylated. Exposure of the receptor to the glycosidases neuraminidase and endoglycosidase H specifically removes sialic acids and asparagine linked carbohydrates, respectively. This treatment reduces the apparent molecular weight of the receptor from all brain regions. However, the reduction was not uniform across all regions suggesting regional differences in post translational glycosylation. Deglycosylation also alters the apparent number of agonist and antagonist binding sites (Table 1) (Sweetnam & Tallman, 1986).

Recently our laboratory has developed monoclonal antibodies directed against the BDZ receptor. These antibodies were initially developed in mice inoculated with affinity purified BDZ receptor. Spleen cells from these mice were fused with myeloma cells to create hybridoma cells. After cloning, individual clones were injected into the peritoneum of syngenic mice for the production of ascites fluid.

Six monoclonal antibodies (mAb) have been developed. The specificity of these mAb's has been confirmed by immunoblotting them to BDZ receptor immobilized on nitrocellulose after SDS electrophoresis. The results demonstrate that the 50K protein is the major protein recognized by these mAb's (Figure 2). Currently we are immunoblotting mAb's to proteins from separate brain regions, in order to identify heterogeneous receptor regions.

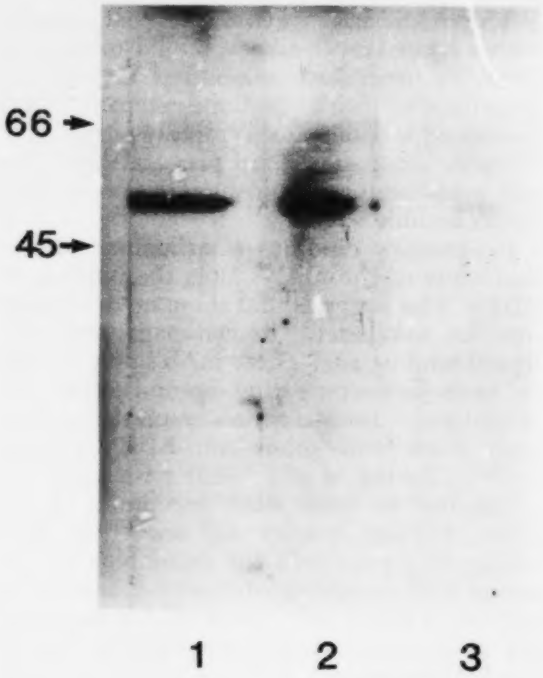

FIGURE 2. Immunoblotting monoclonal antibody 6BE9 onto a purified BDZ receptor preparation. Following separation with SDS/polyacrylamide gel, electrophoresis proteins were electrophoretically transferred to a sheet of nitrocellulose. The sheet was washed for 30 min in phosphate buffered saline containing 0.05% Tween-20 to block further binding of protein to the nitrocellulose. The sheet was cut into strips and each strip was incubated with monoclonal antibody in PBS/Tween or buffer alone (control) overnight at 4°C. The strips were washed and incubated in ^{125}I-labeled antibody to mouse IgG for 1 hr at room temperature. The strips were washed again, dried, and prepared for autoradiography. (1) monoclonal 6BE9 diluted 1:1000 (2) monoclonal 6BE9 diluted 1:100 (3) control strip incubated without monoclonal.

TABLE 1. The Effects of Glycosidase Treatment on Brain Region Specific Benzodiazepine Receptors.

Brain Region	Glycosidase Treatment	Molecular Weight	Agonist		Antagonist	
			K_D	B_{max}	K_D	B_{max}
Cortex	Control	50 K	3.2	535	1.7	520
	Endo-H	40 K	4.7	290	1.1	919
	Neur-Ase	42 K	5.2	250	1.2	840
Cerebellum	Control	50 K	3.9	143	2.9	180
	Endo-H	46 K	4.7	135	2.6	260
	Neur-Ase	50 K	5.2	104	2.1	215

Note. These data suggest a brain regional heterogeneity in carbohydrate moieties as indicated by differing molecular weight changes following enzyme treatment and by the differing Scatchard analysis (K_D expressed as nM and B_{max} as fmol/10 mg tissue).

The mAb's have been used in conjunction with a secondary antibody bound to agarose beads to precipitate solubilized membranes photolabeled with ^{3}H-flunitrazepam. This technique will allow us to rapidly purify BDZ receptor from solubilized preparations. This will make sensitive phosphorylation experiments feasible.

Preliminary binding experiments indicate that some of the mAb's alter the binding of BDZ's. This suggests that these mAb's recognize an antigenetic determinant near the ligand binding site. These mAb's may be useful tools for investigating ligand-receptor interactions. Immunohistochemical studies with these and other anti-BDZ receptor mAb's (Haring et al., 1985) have used the antibodies to stain BDZ receptors in the brain. Further studies will use these antibodies to screen cells for recombinantly inserted BDZ receptors. Monoclonal antibodies will play a major role in elucidating the pharmacology, anatomy, and molecular biology of the BDZ receptor.

Our knowledge of the molecular aspects of the benzodiazepine receptor function is incomplete. The experimental approaches mentioned briefly in this review will make it possible to study the benzodiazepine ligand/receptor interaction at a level which can help us to understand how benzodiazepines induce specific changes in the GABA$_A$ complex and how these changes result in the manifestation of the drugs' actions in the central nervous system. This knowledge will aid in the design of specific drugs to treat anxiety free of unwanted side effects or tolerance. In the future, benzodiazepine receptor research at the molecular level could help define the neurochemical etiology of anxiety.

Postmortem Serotonergic and Adrenergic Receptor Binding to Frontal Cortex: Correlations With Suicide

J. John Mann, M.D.,[1,2] P. Anne McBride, M.D.,[1] and Michael Stanley, Ph.D.[3]

The demonstration that receptor binding studies are feasible in human postmortem brain tissue (Mann et al., 1986) permitted another approach to the evaluation of the functional status of monoaminergic systems in the human central nervous system. In earlier postmortem studies (Shaw et al., 1967; Pare et al., 1969; Beskow et al., 1976; Bourne et al., 1968; Lloyd et al., 1974), levels of serotonin (5-HT) and 5-hydroxyindoleacetic acid (5-HIAA) were found to be slightly lower in the brainstem of suicide victims compared to controls. However other studies failed to find any alteration in 5-HT or 5-HIAA levels in frontal cortex (Stanley & Mann, 1983) and one study (Cooper et al., in press) reported increased 5-HIAA levels in hippocampus (although postmortem delays were significantly longer in this study). Results from studies (Mann et al., in press) of levels of 5-HIAA in cerebrospinal fluid (CSF) have more consistently demonstrated lower levels in suicide attempters compared to controls. Furthermore violent suicide attempts were more strongly associated with lower levels of CSF 5-HIAA than nonviolent attempts.

Postsynaptic receptor sensitivity generally bears a reciprocal relationship with levels of transmitter exposure. Hence, up- or down-regulation of postsynaptic receptors relative to control values permits inferences to be drawn regarding the presence of reduced or increased presynaptic activity, respectively. Moreover, absolute levels of transmitter or metabolite may be a poor guide to functional status because much of the transmitter may be located in a storage pool not readily available for synaptic release and there may be rapid fluctuations in transmitter turnover during the agonal process. We therefore undertook a study of postsynaptic monoamine receptor binding in the frontal cortex of suicide victims compared to matched controls to assess the functional status of the serotonergic and noradrenergic systems.

Methods and Subjects

Samples were collected from suicide victims who had died by nonpharmacological means and from controls matched for age, gender ratio, postmortem delay, and violence of death. Beta-adrenergic receptors were assayed using ^{3}H-dihydroalprenolol (DHA) and ^{125}I-iodopindolol (PIN). Serotonin-2 receptors (5-HT$_2$) were assayed using ^{3}H-spiroperidol and 1 μM ketanserin to define specific binding. Details of brain collection, storage, dissection, and assays have been described elsewhere (Mann et al., 1986).

Results

A statistically significant 28 percent increase was found in the number of 5-HT receptor (B_{max}) in frontal cortex (Brodmann's area 9) of the suicide group. No differences were found in binding affinity (K_D). Beta-adrenergic binding in suicide victims was increased 78 percent over control values ($p < 0.05$, 2-tailed t test). Beta-adrenergic agonist binding was assessed using ^{125}I-iodopindolol as a ligand and 1 μM isoproterenol. Agonist binding, particularly high affinity agonist binding, is a more sensitive indicator of functionally relevant changes in receptor binding. Both overall beta-adrenergic binding and high affinity agonist binding were increased in tissue pooled from a subgroup of three subjects in the suicide victims compared to three controls.

Discussion

Two other laboratories have assessed 5-HT$_2$ binding in suicide victims and depressed patients. Cooper et al. (in press) found no change in 5-HT$_2$ binding in a series of suicide victims; however, most of these patients were on either antipsychotics or antidepressants which would have lowered 5-HT$_2$ binding. Moreover the postmortem interval was over twice as long as in our study and no saturation binding isotherms were carried out—resulting in reduced accuracy of assay results as well as providing less information regarding binding kinetics. In contrast, Ferrier et al. (in press) controlled for the effects of medication and found a trend for an increase in 5-HT$_2$ binding in the frontal cortex of depressed patients.

Beta-adrenergic binding has been studied by three laboratories. In agreement with our results Zanko and Biegon (1983) reported an increase in B_{max} and no change in K_D in several brain regions in suicide victims. Meyerson et al. (1982) found no change in ^{3}H-DHA binding, but this study did not involve well-matched controls in terms of age, postmortem delay, or method of death. Ferrier et al. (in press) found no change in beta-adrenergic binding in a series of patients dying with a history of MDD.

Our findings indicate upregulation of both 5-HT$_2$ and beta-adrenergic binding. These results would be consistent with reduced serotonergic and noradrenergic transmission. Data from CSF studies, neuroendocrine challenge tests, and assay of 5-HT and 5-HIAA in brainstem generally indicate reduced serotonergic function that would explain upregulation of the postsynaptic 5-HT$_2$ receptors in suicide victims (Mann et al., in press). There are few data regarding noradrenergic indices in suicide and these are inconclusive (Mann et al., in press). Future studies must examine the status of the noradrenergic system in conjunction with the serotonergic system in this condition and should address their correlations with suicide separately from those with depressive illnesses.

Antidepressant drugs downregulate beta-adrenergic and/or 5-HT$_2$ receptors in animal studies after chronic but not acute administration. This effect is in the opposite direction to that observed in suicide victims. Therefore, it may be hypothesized that the antidepressant *and* antisuicidal action of these drugs is mediated via one or both of these receptor populations. This hypothesis may be tested by prospective controlled studies of antidepressants in suicidal patients who are suffering from a psychiatric disorder other than a major depressive disorder. Studies of brain samples from patients on antidepressants antemortem will enable evaluation of the effect of antidepressant treatment on monoamine receptors in patients since findings in animals are not necessarily generalizable to the brain of depressed patients.

Suicide and Adrenocortical Function

James H. Kocsis, M.D.,[1] Sara Kennedy, M.D.,[1] Richard P. Brown, M.D.,[1] J. John Mann, M.D.,[1] and Barbara Mason, Ph.D.[1]

Twenty years ago Bunney and Fawcett reported that elevation of urinary 17-hydroxycorticoids was a specific test for prediction of future suicidal behavior in depressed patients who did not communicate suicidal intent (Bunney & Fawcett, 1965).

Several subsequent studies have examined relationships between abnormalities of the hypothalamic-pituitary-adrenocortical (HPA) axis and occurrence of suicide attempts and the results are summarized in Table 1. Three investigations have found elevated levels of 24-hour urinary 17-hydroxycorticosteroids or urinary free cortisol in patients who had been severely suicidal or who later completed suicide (Bunney & Fawcett, 1965; Bunney et al., 1969; Ostroff et al., 1982) although two other studies involving small numbers of subjects have not confirmed this (Levy & Hansen, 1969; Krieger, 1970). Investigations of relationships between suicidal behavior and plasma cortisol levels, both before and after administration of dexamethasone, have mostly found higher rates of non-suppression on the Dexamethasone Suppression Test (DST) in patients who have attempted or completed suicide compared to non-suicide attempters (Carroll et al., 1981; Coryell & Schlesser, 1981; Targum et al., 1983; Banki & Arato, 1983).

Only one study to date has assessed the relationship between cerebrospinal fluid (CSF) cortisol and suicidal behavior (Traskman et al., 1980). Increased CSF cortisol levels were found in depressed patients; however, levels in depressed patients who had made a suicide attempt were not significantly higher than depressed non-attempters. Normal CSF cortisol values were present in non-depressed suicide attempters.

The purpose of the current report is to summarize results of two additional investigations (Secunda et al., in press; Brown et al., unpublished) of relationships between suicidal behavior and HPA function, to relate these findings to results of prior studies and to discuss practical and theoretical implications.

NIMH Study Methods

One hundred thirty-two hospitalized patients with a diagnosis of Major Depressive Disorder as determined by the Schedule for Affective Disorders and Schizophrenia (SADS) (Spitzer & Endicott, 1978) and the Research Diagnostic Criteria (RDC) (Spitzer et al., 1978) were selected for inclusion in the NIMH-Clinical Research Branch Collaborative Study—Biology of Depression. Eighty-five were classified as unipolar depressives and forty-seven as bipolar depressives. Patients were admitted to one of six university hospital centers participating in the Collaborative Study between 1975–80. Full details about the rationale and methods of the study have been published. (Maas et al., 1980; Secunda et al., 1980).

Specific SADS items were used to assess suicidal thoughts and the number, seriousness, and lethality of previous suicide attempts during the current episode. On the basis of SADS data, patients were assigned to one of three groups: (1) a suicide attempter group (SA), defined as those patients who had made at least one suicide attempt during the current episode which could be considered significant with regard to the seriousness of its intent and/or its medical lethality; (2) a non-attempter group (NA), defined as those patients with no history of suicide attempts for either the current or past episodes; and (3) an unclassified group (UC) consisting of patients who had made a suicide attempt during the current episode which did not meet the established "significant" criteria and patients who had a history of suicide attempts during prior episodes. Except where noted, the UC group was excluded from data analyses. Severity of depression was assessed using the Hamilton Depression Rating Scale (HRS-D) and the Global Assessment of Severity (Endicott et al., 1976), a measure of coping mechanism and degree of impairment.

Within 2 weeks of admission three successive morning and one evening plasma cortisol levels, 24-hour urine collection for urinary free cortisol, and a CSF cortisol level were obtained. Subsequently, 1 mg of dexamethasone was given orally in liquid solution, under observation of a nurse at 10:40 p.m. The following day, post-DST plasma cortisol levels were obtained at 8:30 a.m., 4 p.m., and 10 p.m. During the 24-hour period following dexamethasone administration, urine was collected to measure urinary cortisol. DST nonsuppression was defined as an a.m. post-dexamethasone plasma cortisol of 5 μg/dl or more. Urine free cortisol hypersecretion was defined as more than 133 mg/24 hour (Stokes et al., 1984).

Cornell Study Methods

Sixty-six inpatients, who participated in depression research protocols on the clinical research unit at the Payne Whitney Psychiatric Clinic during 1982–84 and also met *DSM-III* criteria for primary Major Depressive Disorder (American Psychiatric Association, 1980), were included. Patients were categorized as attempters if a suicide attempt requiring medical intervention or hospitalization had been made within 4 weeks prior to hospitalization. Ten patients had a past history but no recent history of suicide attempts, and were dropped from the analysis. A further evaluation of suicidal ideation was completed at the time of the administration of dexamethasone and at the time of drawing cortisol levels. Severity of depression was assessed using the HRS-D. Blood samples were collected at 9 a.m. and 4 p.m. on the day before and the day after administration of 1 mg of dexamethasone orally at 11 p.m. under observation by a nurse. DST nonsuppression was defined as either the 9 a.m. or 4 p.m. plasma cortisol greater than 5 μg/dl (Brown et al., unpublished).

No patient in either sample had major medical illnesses or was taking medication known to affect cortisol levels or DST results. Patients were not treated with antidepressant medication until after cortisol measures were obtained. CSF plasma and urinary free cortisol for both studies were measured in one laboratory by radioimmunoassay by methods previously described in detail (Stokes et al., 1984).

Results from the NIMH Study

The demographic and clinical characteristics of the suicide attempters and non-attempters have been reported (Secunda et al., in press). No differences were found with regard to sex, polarity, duration of current episode, number of previous episodes, presence of psychotic features, or recovery status. Suicide attempters were significantly younger and had an earlier age at onset than non-attempters. Non-attempters showed more depressive symptoms, higher levels of anxiety, agitation, and somatization and greater psychomotor retardation than did the suicide attempter group.

Analyses of covariance performed on the various HPA measures revealed few differences between the attempter and non-attempter group (Table 2). Among the plasma, CSF, and urinary cortisol comparisons made, only the pre-DST evening plasma cortisol sample was significantly different, being lower in the suicide attempter group. The results of statistical analyses performed on the post-DST plasma cortisol levels (i.e., suppressors versus non-suppressors) and on urine free cortisol hypersecreters versus normal secreters did not reveal significant differences between attempters and non-attempters (see Table 2).

Pearson product moment correlations between the HPA variables and scores on the SADS Suicidal Ideation and Behavior Scale and the individual items which comprise the scale were performed on the entire depressed population (including the UC group). None of these achieved the .05 level of significance.

Results from the Cornell Study

The mean age of attempters was 63 ± 11 (SD) and of non-attempters was 61 ± 14. Female:male ratios were approximately two to one for attempters and non-attempters. Baseline mean HRS-D scores were 34 ± 11 for attempters and 32 ± 9 for non-attempters. None of these differences were significant.

Morning and evening cortisol levels before and after dexamethasone did not differ significantly between groups (Table 3). There was also no significant difference between attempters and non-attempters in frequency of cortisol suppression in the morning or afternoon following dexamethasone. Furthermore, no significant differences were found in cortisol levels between those patient groups rated as currently having active suicidal intent, passive suicidal ideation, or no suicidal ideation.

Correlations among cortisol levels and other variables possibly related to suicidality were also calculated. Significant positive correlations included the following: presence of delusions and both pre- and post-dexamethasone morning and afternoon cortisol levels ($r = .41$, $p = .001$; $r = .43$, $p = .001$, respectively); and age and morning and afternoon post-dexamethasone cortisols ($r = .39$, $p = .001$; $r = .84$, $p = .001$, respectively).

Discussion

The possibility that hyperactivation of the pituitary-adrenal axis might have a special relationship to suicidal behavior was initially suggested by the empirical observation of elevated urinary corticosteroids in patients who later committed suicide (Bunney & Fawcett, 1965). Several subsequent studies investigating this association have yielded mixed results

(Levy & Hansen, 1969; Bunney et al., 1969; Krieger, 1970; Traskman et al., 1980; Carroll et al., 1981; Coryell & Schlesser, 1981; Ostroff et al., 1982; Targum et al., 1983; Banki & Arato, 1983). Thus, further research was merited to clarify these issues.

The current report summarizes findings from two additional studies done in hospitalized depressed patients comparing results of measures of HPA function in suicide attempters versus non-attempters (Secunda et al., in press; Brown et al., unpublished). The main findings are a lack of significant HPA differences in these two subgroups. One significant difference was found in the two studies and this was in the direction opposite of what was predicted. Evening plasma cortisol concentrations in the Collaborative Study were higher in non-attempters on the day prior to administration of dexamethasone ($p <$ .05 by ANCOVA).

Relationships between HPA function and suicidal acts are clearly not simple. Clinical research in this area is likely to have been confounded by numerous interacting variables, which are difficult to control in any single study. These would include age, presence or absence of psychosis, recent weight loss, levels of anxiety and agitation, psychiatric diagnosis, method of suicide attempt, and proximity of the biological sampling to the suicidal act.

The Cornell study patient ages were similar in the attempter and non-attempter groups. However, in the NIMH study attempters were younger than non-attempters. The latter situation would work against finding increased HPA activity in the attempter sample, because increased age is a known correlate of higher HPA activity (Kocsis et al., 1985). Presence of psychosis in depression has also been associated with both HPA activation and suicidality in some but not all previous studies (Schatzberg et al., 1983; Kocsis et al., unpublished). The current study from New York did find an association between delusions and higher cortisol levels. However, neither study reported significant differences in suicidality between delusional and non-delusional patients. HPA studies conducted separately in psychotic and non-psychotic depressed patients will help to resolve these questions.

Weight loss, anxiety, and agitation were all found to correlate with HPA measures in the NIMH study (Kocsis et al., 1985). Unfortunately data on these possibly confounding variables were not compared between attempters and non-attempters in the present studies. Such analyses are suggested for future research.

Psychiatric diagnoses were carefully established in both of the current studies by research psychiatrists who had established diagnostic reliability. All subjects were diagnosed as having Major Depressive Disorders by RDC or *DSM-III* criteria. It is possible that suicide attempters and non-attempter samples in other studies have contained either mixed or unreliable diagnoses. Such samples might create a bias for both suicide and abnormal HPA function to cluster in the subgroups with major depressive disorders, and thus yield a spurious impression that suicidal behavior has a special association with the endocrine findings.

Method of suicide attempt may also be an important variable because previous research has suggested links between inwardly and outwardly directed aggression and brain serotonin systems in humans, based on CSF studies in patients who used violent methods of attempting suicide (Asberg & Traskman, 1981). Although prior studies of suicide and HPA function have not reported linkage with method of suicide act, this remains at least a theoretical possibility.

Whether associations between suicidal behavior and biology are confounded by the proximity between the times of the biological sampling and the suicide attempt would depend on whether the putative biological marker is state or trait-related. For example, low CSF serotonin has been suggested as a trait marker for aggressive acts and violent suicide attempts (Asberg & Traskman, 1981) because the altered biochemistry appears to persist long after a suicide act. On the other hand behavioral assessments performed in suicidal subjects before and after their attempts have demonstrated distinctive patterns prior to suicidal behavior with reversion back toward patterns seen in non-suicidal patients following an attempt (Mason et al., in press). This kind of observation raises important questions about the longitudinal patterns of potential biological markers for suicidality. Specifically, in the case of HPA function, increased activation associated with state of arousal prior to a suicide attempt could theoretically revert to normal following the attempt. All of HPA measures in the current studies were obtained in subjects who had attempted suicide earlier during their current illness episode. Thus, some prior studies, which have evaluated HPA function in patients who later committed suicide, might have their discrepant findings explained on the basis of different temporal sequences between biological sampling and the suicidal act.

In conclusion, this brief review has summarized results from two recent studies of relationships between suicidal behavior and adrenocortical activity in depressed psychiatric inpatients. Hopefully a consideration of these findings and the discussion of previous studies and of factors which can influence these relationships will help to alert investigators in the biology of suicide to methodological considerations and important unresolved questions to be answered in future studies.

Suicidal Potential in Depression: Focus on CSF Monoamine and Purine Metabolites

Hans Ågren, M.D., Ph.D.,[1] and Frank Niklasson, M.D., Ph.D.[2]

Introduction

Biochemical differences between depressed individuals who have or who have not committed suicidal acts were proposed already in 1965 by Bunney and Fawcett, suggesting that suicidal patients have an elevated 17-hydroxycorticosteroid output. A broader interest in the field did not develop until Åsberg and her colleagues reported lower levels of 5-hydroxyindoleacetic acid (5HIAA) in the cerebrospinal fluid (CSF) of depressed patients who made violent suicide attempts when compared with non-suicidal depressives (Åsberg et al., 1976). Focus on serotonin is now established in biochemical research on suicide (Träskman et al., 1981; van Praag, 1982), and post-mortem findings of altered serotonin receptors in suicides add to its importance (Stanley and Mann, 1984).

A growing number of reports state that changes in CSF monoaminergic indices other than 5HIAA also are or become deranged in suicidal states. At least three studies have found a reduction in CSF homovanillic acid (HVA) in suicidal depression that is more pronounced than that of 5HIAA (Montgomery and Montgomery, 1982; Ågren, 1983; Roy et al., 1986). Furthermore, we have reported low concentrations of the purine metabolites xanthine and hypoxanthine (Ågren et al., 1983) as well as CSF creatinine, a marker of cerebral metabolism (Niklasson et al., 1983) to correlate with suicidal ideation. The significant intercorrelations between all these CSF indices of monoamine and purine metabolism raise statistical problems of collinearity that must be addressed before a specific neurotransmitter system can be singled out to play a major role in the biochemical substrate of suicidal mood states. The present study attempts to compare the relative contributions of a number of CSF monoaminergic and purinergic indices as well as psychoendocrinological variables in retrospectively "accounting" for previous suicidal acts in a large sample of patients with major depressive disorders.

Methods

Patients

Table 1 shows the composition of the patient sample, all inpatients at the Department of Psychiatry, University Hospital at Uppsala, Sweden, and suffering from major depressive disorders. They were diagnosed according to Research Diagnostic Criteria using the Schedule of Affective Disorders and Schizophrenia (SADS) (Endicott and Spitzer, 1979). Scores for the Hamilton Depression Rating Scale (HRS-D) were deduced by converting appropriate SADS items following rules laid down by Endicott et al. (1981).

TABLE 1. Composition of the Patient Sample.

	Males	Females
n	66	85
Age ± SD	42.7 ± 12.5	40.1 ± 12.7
HRS-D ratings for worst week ± SD	25.5 ± 6.6	25.2 ± 6.8
HRS-D ratings for past week ± SD	18.2 ± 9.0	18.8 ± 9.1

HRS-D = Hamilton Depression Rating Scale extracted from the SADS (Endicott et al., 1981).

Biochemical Analyses

Monoamine metabolites HVA, 5HIAA, and 3-methoxy-4-hydroxyphenylglycol (MHPG) in CSF and MHPG in 24-hour urinary samples were assessed by gas chromatography–mass spectrometry by L. Svennerholm (Andersen et al., 1981). CSF purine metabolites xanthine and hypoxanthine as well as creatinine were analyzed by high pressure liquid chromatography (Niklasson and Ågren, 1983). Analyses of plasma cortisol for dexamethasone suppression tests, urinary free cortisol (UFC), and plasma thyroid-stimulating hormone (TSH) for thyroid-releasing hormone (TRH) stimulation test were carried out using radioimmunological assays as described by Ågren and Wide (cortisol: 1982; TSH: 1986).

Statistics

Ordinary *t* tests were used for comparisons of means in the previous-suicide-attempts and no-previous-suicide-attempts groups. Multiple regression analyses were done with ranked independent variables, permitting common parametric test procedures to be used in a non-parametric application (Conover and Iman, 1981). Statistical Analysis System, Inc., procedures were used.

Results

Univariate Differences in Means

Table 2 shows statistically significant differences between the suicidal and non-suicidal groups in six variables considered (the suicide group includes disproportionately more bipolar patients; patients are shorter in stature; patients are marked by lower CSF HVA, CSF MHPG, urinary MHPG, and CSF xanthine). Differences at trend probability were found in two variables (lower CSF 5HIAA and CSF creatinine). Non-significant differences were seen in seven other variables (weight, CSF hypoxanthine and five psychoendocrine measures).

Multivariate Analyses With Suicide Measures as Dependent Variables

All variables listed in Table 2 were ranked and used as independent variables in stepwise multiple regressions employing the forward maximum R^2 improvement technique. Analyses were run for the whole patient group as well as separately for unipolar and bipolar patients. The HRS-D score for the week preceding tests was forced to be included first. The suicide/non-suicide dichotomy and SADS item 247 (Suicidal Tendency and Ideation for past week) were used in turn as independent, "predicted" variables.

TABLE 3. Final Selection of Ranked Independent Variables "Predicting" Previous Suicidal Acts.

Dependent variable: Ever Attempted Suicide (Yes/No)				
All patients:	$R^2 = 0.136$;	$F = 5.64$;	df = 4,144;	$p = 0.0003$
Unipolars:	$R^2 = 0.145$;	$F = 4.12$;	df = 4,97;	$p = 0.0040$
Bipolars:	$R^2 = 0.189$;	$F = 2.39$;	df = 4,41;	$p = 0.066$
Independent variables:				
(Type III Sums-of-Squares)		*F*		*p*
Hamilton scores Past Week	All	6.35 +[a]		0.013
	Unip	3.38 +		0.069
	Bip	5.64 +		0.022
Body height	All	6.66 −		0.011
	Unip	2.15 −		NS
	Bip	2.66 −		NS
CSF HVA	All	5.59 −		0.020
	Unip	6.99 −		0.0096
	Bip	0.01 −		NS
CSF MHPG	All	3.01 −		0.085
	Unip	3.11 −		0.081
	Bip	0.00 −		NS

[a] This sign indicates the direction of the regression coefficient.

Table 3 shows high HRS-D scores for past week, a short body stature, and low CSF concentrations of HVA and MHPG to retrospectively "predict" the existence of previous suicidal acts, but only in the context of unipolar depression. For the undivided group, short stature and low CSF HVA significantly "predict" earlier suicidal acts even when influence of severity of current depression has been covaried out. Low CSF MHPG contributed at trend significance. When only unipolars were considered, the importance of CSF HVA strengthened. Among bipolar patients, only current depressive severity was of any significant importance. Adding multiplicative terms checking for interactions between the independent variables did not reveal any significant increases of overall degree of explanation.

A discriminant analysis using the above four variables to "predict" previous suicidal acts classified 86/100 non-suicide attempters and 16/51 suicide attempters correctly (χ^2 = 7.55, df = 1, p <0.01). Thus, specificity was 86 percent but sensitivity only 31 percent.

Table 4 shows the result from a stepwise analysis "predicting" current suicidal tendency. Adding a multiplicative term [(CSF 5HIAA) times (post-DST plasma cortisol at 8 p.m.)] yielded a significant increase in R^2 for

TABLE 4. Current Suicidal Ideation "Predicted" by a Selection of Ranked Independent Variables.

Dependent variable: Suicidal tendency past week				
All patients:	$R^2 = 0.561$;	$F = 28.79$;	df = 4,90;	$p < 0.0001$
Unipolars:	$R^2 = 0.573$;	$F = 20.76$;	df = 4,62;	$p < 0.0001$
Bipolars:	$R^2 = 0.638$;	$F = 9.68$;	df = 4,42;	$p < 0.0001$
Independent variables:				
(Type III Sums-of-Squares)		*F*		*p*
Hamilton scores Past Week	All	83.51 +[a]		0.0001

the whole sample. As could be expected, results indicate that current severity of depression is overwhelmingly important in accounting for current suicidal thoughts, but that even when this factor is under control, low CSF concentrations of 5HIAA and a more effective cortisol suppression by dexamethasone are highly significant predictors among unipolar patients. Again, in bipolar patients, CSF 5HIAA and the cortisol variable did not reach individual significance.

Discussion

This study of multiple biochemical sources of variance for suicidal parameters in clinically depressed patients offers arguments to modify the serotonin deficiency hypothesis for suicidal acts. First, certain CSF metabolites other than 5HIAA are associated with previous suicidal acts, especially HVA. A conjecture that the signals from the suicide source actually originate from a disturbed CSF flow or spinal reuptake mechanism needs to be addressed in future studies. The highly significant positive correlation between CSF HVA and 5HIAA presents intricate statistical problems of collinearity. We have dealt with the implications of this association elsewhere (Ågren et al., 1986). Furthermore, the very notion of "low" CSF 5HIAA in suicidal depression has been challenged by Roy et al. (1986), who report a non-significant difference between suicidal depressed patients and normal controls. The well-known negative association between body height and CSF HVA and 5HIAA (discussed by Ågren et al., 1986) is apparently reflected in the form of short stature paradoxically reaching importance as a "suicide predictor." In a short individual, low CSF HVA and 5HIAA would conceivably carry a purer suicide signal since shortness per se would tend to "increase" the metabolite levels.

Second, the specificity issue of disturbed monoamine metabolite regulation in suicidal behavior needs attention. Low CSF 5HIAA has been argued to differentiate impulsive from non-impulsive behavior irrespective of affective diagnosis (Brown et al., 1982; Linnoila et al., 1983). Low CSF 5HIAA was associated with suicidality in schizophrenic patients in one NIMH study (Ninan et al., 1984) but not in another (Pickar et al., personal communication). Contrasting against this broader view of the importance of low CSF 5HIAA stand reports that the associations only hold in unipolar, not bipolar depression (Ågren, 1983; Post et al., personal communication; this study). In a negative study of CSF 5HIAA and suicide in affective disorder (Roy-Byrne et al., 1983), 32 out of the 45 patients investigated were bipolars. We found, however, that bipolar patients had more often tried to commit suicide than unipolar depressives. This possible difference needs more work before anything specifically can be stated about subdiagnostic differences in suicidal potential: bipolars are likely to have experienced more depressive episodes and thus to have been subjected to a more intense wearing-out effect of depression as such.

Third, psychoendocrine variables (DST, UFC, ΔTSH) in isolation failed to relate to the suicide variables in focus. However, in combination with CSF monoamine metabolites, DST status helped increase the power of CSF 5HIAA and HVA to "predict" current suicidal tendencies. Similar conclusions concerning interactions between hypercortisolism, CSF HVA, and suicidality have been reached earlier on a smaller sample of Swedish patients (Ågren, 1983) and in a recent NIMH study (Roy et al., 1986).

In conclusion, several measures, mainly monoamine metabolite concentrations in lumbar CSF, have been related to setting the stage for a suicide act. The degree of significance of the correlations and the question of which one is the strongest candidate to reach the status of a specific suicide marker differs between studies. These inconsistencies suggest a common denominator that lies behind both suicidality and the lumbar CSF metabolite levels. Partly for this reason, renewed attention should focus on the dynamics of CSF flow and its implications for concentrations of small molecules in lumbar CSF.

Summary

Low levels of monoamine metabolites in lumbar CSF, especially 5HIAA, have repeat-

edly been linked with previous suicidal acts in depressive and other psychiatric patients. This study compared the relative contribution of a number of monoamine and purine metabolites in CSF and DST and TRH stimulation tests on 151 patients with RDC major depressive disorders. Restricted to unipolar patients, we found that low CSF HVA and short stature best "predicted" previous suicidal acts and did so better than CSF 5HIAA and that low CSF 5HIAA and DST status predicted current suicidal ideation, even when current depressive severity was accounted for. Collinearity between indices creates problems in singling any one out as a suicide marker, and possible unaccounted sources of variance lying behind both alterations in CSF indices and suicidality may confuse correlational analyses.

Monoamines, Glucose Metabolism, Suicidal and Aggressive Behaviors

Alec Roy, M.B., Matti Virkkunen, M.D., Sally Guthrie, Pharm.D., Russell Poland, Ph.D., and Markku Linnoila, M.D., Ph.D.[1]

In 1976 Asberg et al. reported a bimodal distribution of levels of the serotonin metabolite 5-hydroxyindoleacetic acid (5-HIAA) in the lumbar cerebrospinal fluid (CSF) of depressed patients. Significantly more of the patients in the low CSF 5-HIAA mode had attempted suicide in comparison with those in the high mode. Since then there have been other studies in personality-disordered, schizophrenic, and depressed patients also reporting an association between low levels of CSF 5-HIAA and aggressive and suicidal behaviors (reviewed by Asberg et al., 1986). It is of note that some investigators have associated low CSF 5-HIAA levels particularly with violent suicide attempts (Banki et al., 1984). In fact, in an early study Traskman et al. (1981) reported that CSF 5-HIAA levels were significantly lower only among those patients who had made a violent suicide attempt and that levels were not reduced among those who had made a nonviolent suicide attempt.

Violent Offenders

Initial studies of CSF 5-HIAA levels and aggressive behaviors were reported by Brown et al. (1979, 1982). Recently Linnoila et al. (1983) examined CSF 5-HIAA levels among 36 male murderers and attempted murderers. Twenty-seven of them formed a group of impulsive offenders, 20 had an intermittent explosive disorder, and 7 an antisocial personality disorder; all also met criteria for borderline personality disorder and alcohol abuse. Nine violent offenders who had premeditated their crimes formed the non-impulsive group and had paranoid or passive-aggressive personality disorders. The authors found that CSF 5-HIAA levels were significantly lower among the group of impulsive violent offenders than among the non-impulsive violent offenders (Figure 1). Also, the 17 offenders who had committed more than one violent crime had CSF 5-HIAA levels significantly lower than those who had committed only one violent crime (mean 67.9 ± 12.1 vs. 87.1 ± 23.7 nM, $p < 0.02$). Furthermore,

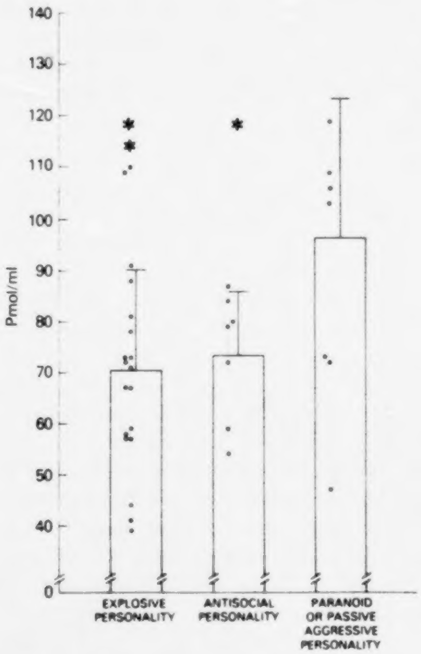

FIGURE 1. CSF 5-HIAA concentration in three diagnostic subgroups of violent offenders. The explosive personality ($n = 20$) and antisocial personality ($n = 7$) subgroups are classified as impulsive offenders, whereas the paranoid or passive-aggressive personality subgroup ($n = 9$) is classified as nonimpulsive. ANOVA $p < .01$ between the groups. Two-tailed, students *t*-tests compare the two impulsive subgroups with the nonimpulsive subgroup; ** = $p < .01$, * = $p < .05$.

the impulsive offenders who at some time had attempted suicide were found to have significantly lower CSF 5-HIAA levels than violent offenders who had never attempted suicide (Figure 2). There were no significant differences for CSF levels of free testosterone (Figure 3). The power to detect a significant difference ($p < 0.05$) in the mean free testosterone levels of these three groups was only 25 percent. However, for this comparison to have an 80-percent probability of finding a significant difference (should such a difference exist) each group would have to contain in excess of 700 subjects.

Because of these findings Linnoila et al. suggested that low CSF 5-HIAA levels may be associated with a tendency towards impulsive violent behavior which may manifest itself either as violence towards others or as suicide attempts. The authors cautioned that the implications of their study are presently limited as the number of subjects was relatively small and consisted of offenders who had exhibited extreme forms of impulsive violent behavior. However, they speculated that there may be individuals who have a defect in their central serotonin metabolism who, at an early age start to abuse alcohol, and later manifest impulsive violent behavior towards themselves and others. Furthermore, they suggested that experimental prospective prophylactic studies with serotonergic drugs should be considered, particularly for impulsive individuals who also have a family history of impulsive behavior.

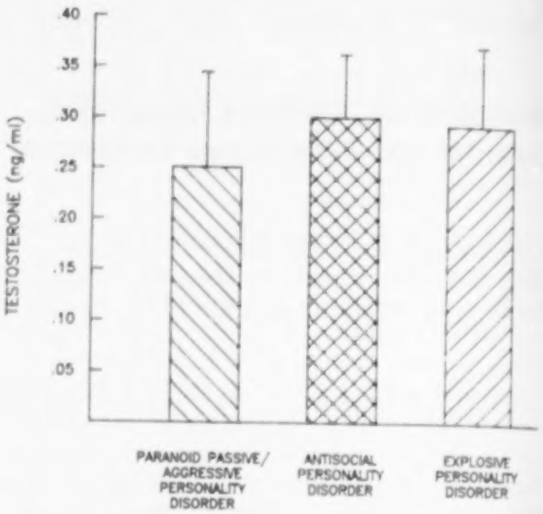

FIGURE 3. CSF free testosterone concentrations in paranoid or passive-aggressive personality disorder ($n = 12$), explosive personality disorder ($n = 19$), and antisocial personality disorder ($n = 10$) subgroups. There were no significant differences between group means.

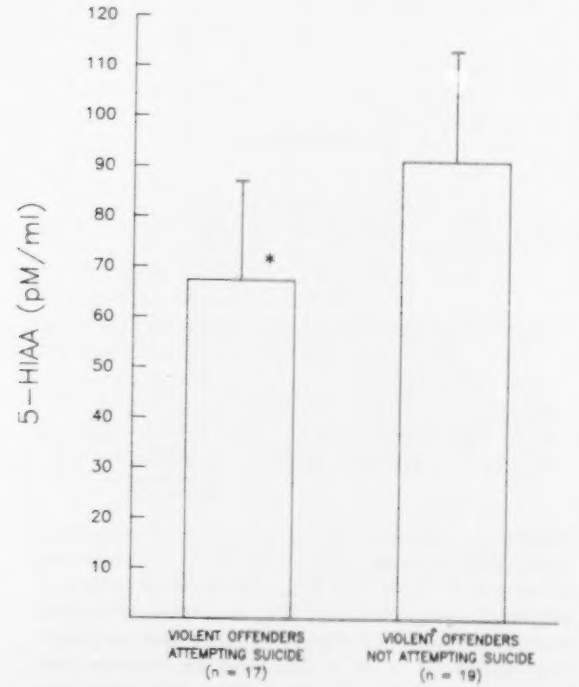

FIGURE 2. CSF 5-HIAA concentrations in violent offenders who had or had not attempted suicide. Two-tailed, student's *t*-test; * = $p < .05$.

Arsonists

In a later study Virkkunen et al. (1986) performed lumbar punctures on 20 male arsonists matched with a subgroup of the previously studied violent offenders and also compared with 10 normal controls. CSF 5-HIAA levels were significantly lower among the arsonists than the other two groups (Figure 4). When patients who had made past violent suicide attempts were excluded, arsonists again showed significantly lower CSF 5-HIAA and CSF MHPG levels than the other two groups (Figure 5).

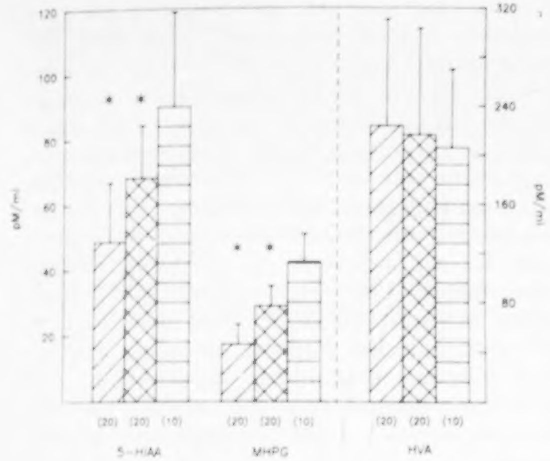

FIGURE 4. CSF monoamine metabolites in arsonists ($n = 20$), violent offenders ($n = 20$), and normal controls ($n = 10$). Post hoc student's t-tests comparing violent offenders or arsonists to normal controls; * = $p < .001$.

All of the arsonists also met DSM-III criteria for borderline personality disorder and many of them had exhibited occasional explosive behavior, usually after consuming alcohol. Thus, Virkkunen et al. argued that these results also suggest that low brain serotonin turnover, as indicated by low CSF 5-HIAA levels, may be associated with poor impulse control.

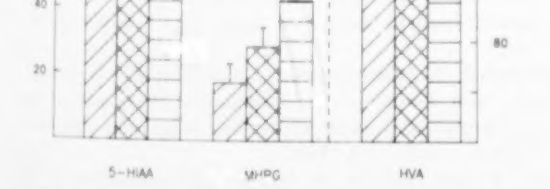

FIGURE 5. CSF monoamine metabolites in arsonists ($n = 9$), violent offenders ($n = 11$), and normal controls ($n = 10$), who had not attempted suicide. Post hoc student's t-tests comparing violent offenders or arsonists to normal controls; * = $p < .001$, + = $p < .05$.

Reactive Hypoglycemic Tendency

Virkkunen (1982, 1983, 1984, 1985a,b) also investigated glucose metabolism among these violent and impulsive offenders, half of whom had exhibited suicidal behavior. Blood-glucose levels fell below the basal level to a nadir of 2.4 ± 0.5 mmol/l in the antisocial personality group ($n = 37$) and to 2.3 ± 0.4 mmol/l in the intermittent explosive disorder group ($n = 31$). The blood-glucose nadir for controls ($n = 29$) was 3.1 ± 0.5 mmol/l, which was significantly higher than that found in both impulsive, violent offender groups ($p < .001$). A long duration of hypoglycemia correlated with a low verbal IQ, the presence of tattoos and slashing scars, and behavioral and sleeping problems. There were also significant positive correlations between the duration of hypoglycemia and truancy, stealing, number of crimes against property, having multiple sentences, and having a father who was violent under the influence of alcohol. Also, among 59 arsonists 27 (45.8 percent) had a glucose nadir under 3.0 mmol/l compared with only 5 of 29 male controls (17 percent; $p < .01$).

Among 23 young violent offenders with antisocial-personality disorder, insulin secretion during the GTT was found to be greater in those who also had an early undersocialized aggressive-conduct disorder. Day-night rhythm disturbances, sleeping difficulties, and behavioral problems during the evaluation were also more characteristic of subjects who developed high insulin peak values. In rats lesions of the suprachiasmatic nucleus abolish circadian rhythms of sleep and feeding, hyperglycemic responses to intracranial injection of 2-deoxy-D-glucose, and produce hyperinsulinaemia and enhanced-insulin secretion similar to that seen in impulsive violent offenders and arsonists after an oral or intravenous glucose load (Yamamoto et al., 1985). As the suprachiasmatic nucleus has a major serotonergic input from the raphe nuclei, one might speculate that deficient brain serotonin systems in impulsive violent offenders produce the insomnia and changes in feeding and glucose metabolism through a dysfunction of suprachiasmatic regulatory mechanisms.

Alcoholics

It is estimated that approximately 15 percent of alcoholics die by committing suicide and a high percentage attempt suicide (reviewed by Roy and Linnoila, 1986). Takahashi et al. (1974) reported that alcoholics with delirium tremens and other florid abstinent symptoms had significantly lower CSF 5-HIAA levels than controls and that after 4 weeks of supervised abstinence CSF 5-HIAA levels remained low. Takahashi et al. speculated that abnormality of brain serotonin metabolism might be a factor causing the psychiatric symptoms, including suicidal ideation, that are commonly found among alcoholics. Later, Ballenger et al. (1979) found that CSF 5-HIAA levels were significantly lower in alcoholics during the abstinent phase than in the postintoxication phase, or when compared to levels found in personality-disordered controls free of drinking problems. Moreover, Banki (1981) found a significant negative correlation between the number of days abstinent and CSF 5-HIAA levels. Also, depressed patients, themselves free of drinking problems, but with a positive family history of alcoholism, had significantly lower CSF levels of both 5-HIAA and of the norepinephrine metabolite 3-methoxy-4-hydroxyphenylglycol (MGPG) (Rosenthal et al., 1980) than depressed patients without a family history of alcoholism.

Ballenger et al. (1979) suggested that alcoholics may have a low brain serotonin turnover rate, which is transiently elevated by alcohol consumption. This in turn eventually leads to further depletion of brain serotonin. They speculated that a pattern may become established where the alcoholic drinks repeatedly in order to pharmacologically modify a serotonin deficiency in the brain.

Conclusion

A number of reports suggest that a deficiency of the serotonin system may be associated with disorders characterized by episodic deficits of impulse control and alcoholism. Furthermore, hypoglycemia during the oral glucose tolerance test and insomnia are very common among individuals with poor impulse control and a low CSF 5-HIAA concentration. Recent animal research has implicated the suprachiasmatic nucleus, which has a dense serotonergic innervation, as playing an important role in controlling both circadian rhythms and glucose metabolism. The insomnia of individuals with poor impulse control may be an indicator of circadian rhythm disturbance. Thus, we postulate that a functional serotonergic deficit may be conducive of poor impulse control, circadian rhythm and glucose metabolism disturbances, and that these disturbances are conducive of violent outbursts, suicide attempts, and alcohol abuse.

Genetic Factors in Suicide

Alec Roy, M.B.[1]

Suicide is a multidetermined act (Roy, 1985a) and evidence about genetic factors comes from a wide range of studies.

Clinical Studies

A family history of suicide has been noted in a small but significant percentage of individuals who commit suicide (Farberow & Simon, 1969; Roy, 1982; Shaffer et al., 1974; Stengel, 1964). Also, significantly more psychiatric patients with a family history of suicide themselves attempt suicide than patients without such a family history (Roy, 1983; 1985b). Linkowski et al. (1985), examining a consecutive series of psychiatric inpatients with affective disorders, also found that a family history of suicide significantly increased the frequency of violent suicide attempts in both depressed women and men.

A family history of suicide is associated with attempts at suicide throughout the life cycle. Among the young, Garfinkel et al. (1982) found that a family history of suicidal behavior was found significantly more frequently among 443 adolescents who presented to hospital having attempted suicide than among 442 adolescent controls who had not attempted suicide (37 vs. 5, $p<0.01$). Among adults, Murphy et al. (1982) reported that 14 percent of 127 patients admitted after an attempt at suicide had a family history of suicide. Among the elderly, Batchelor and Napier (1953) studying individuals over 60 years of age who had attempted suicide, noted that 12.5 percent had a family history of suicide.

How commonly a family history of suicide is found among psychiatric inpatients can be determined from the data in the studies of Pitts and Winokur (1964) and Roy (1983). These two studies found that approximately 4 to 5 percent of psychiatric inpatients have a family history of suicide and that between 50 percent to 66 percent of inpatients with such a history have a diagnosis of affective disorder (Roy, 1985b). Approximately 10 percent of manic-depressive patients have a family history of suicide (Roy, 1985c).

Twin Studies

In 1967, Haberlandt examined all the reports in the world literature concerning a twin who had committed suicide. He identified 149 reports since 1830. There were 9 twin pairs where both twins had committed suicide. All 9 of these twin pairs were found among the 51 identical twin pairs (17.7%) and none among the 98 nonidentical twin pairs. This is a highly significant difference between identical and nonidentical twin pairs ($p<0.0001$) and is strong evidence that there are genetic factors in suicide. Furthermore, in several other of the 149 twin pairs the living twin had attempted suicide—again in all cases this was found among identical twin pairs. It should be noted that 4 of the 9 twin pairs concordant for suicide were also concordant for psychiatric disorder—in 3 twin pairs this was for affective disorder while the fourth pair was concordant for schizophrenia.

The Iowa 500 Study

The 30- to 40-year follow-up study of the 685 selected psychiatric patients and surgical controls admitted to hospital in Iowa City between 1934 and 1955 revealed that there had been 30 suicides—29 among the 727 psychiatric patients (5.5%) and 1 among the 160 controls (0.6%) ($p<0.001$). Tsuang (1983) recently reported the follow up of the 5,721 first-degree relatives of this cohort. He found that the risk of suicide in the relatives of the psychiatric patients (2.3%) was nearly eight times greater than the risk among the relatives of the surgical controls ($p<0.01$). Furthermore, the relatives of patients who had committed suicide had a four times greater risk themselves of committing suicide than the relatives of patients who had not committed suicide (7.9% vs. 2.1%, $p<0.05$). These findings support "the presence of a genetic element in suicide." Interestingly, the increased risk of suicide for relatives of patients who had committed suicide was confined to the relatives of the bipolar and unipolar patient suicides.

Amish Study

Suicide among the Old Order Amish of Lancaster County in Pennsylvania has been studied by Egeland and Sussex (1985). This community is of particular interest, as some of the sociodemographic correlates of suicide derived from general population studies are not found among the Amish. This is because they are a pacifist, nonviolent, agrarian society, alcohol is prohibited, there is no unemployment, no social isolation, and there is no lack of social support as three generations live together under the same roof.

However, during the hundred years between 1880 and 1980 there were 26 suicides in this community. Detailed psychological autopsies indicate that 92 percent of the individuals who committed suicide suffered from affective disorder. Furthermore, three-quarters of the suicides clustered in four pedigrees, each of which contained a heavy loading of affective disorders and suicide. Egeland and Sussex concluded that individuals with a major affective disorder and a family history of suicide themselves have an increased risk of suicide.

Adoption Studies

The strongest evidence that there are genetic factors in suicide comes from the Danish Adoption Studies of Schulsinger et al. (1979). The Psykologisk Institut in Copenhagen has a register of the 5,483 adoptions that occurred in the greater Copenhagen area between 1924 and 1947. A screening of the registers of causes of death revealed that 57 of these adoptees had committed suicide. These 57 suicides were matched with adopted controls for sex, age, social class of the adopting parents, and time spent both with their biological relatives and in institutions before being adopted. Searches of the registers of causes of death revealed that 12 of the 269 biological relatives (4.5%) of these 57 adopted suicides had themselves committed suicide compared with only 2 of the 269 biological relatives (0.7%) of the 57 adopted controls ($p<0.01$). None of the adopting relatives had committed suicide. Also, 6 of the 12 biological suicide relatives of the adopted suicide victims had a psychiatric history.

In another study this group compared the 71 adoptees known to have suffered from depressive disorder with 71 matched adopted controls. Fourteen of the 407 biological relatives (3.7%) of the adoptees with depression were found to have committed suicide compared with only 1 of the 360 (0.3%) biological relatives of the controls ($p<0.01$). Of particular interest was the finding that the type of depressive disorder among the adoptees most significantly associated with suicide among their biological relatives was the diagnosis of "affective reaction." This is a diagnosis often given in Denmark to individuals who have attempted suicide and who have associated affective symptoms.

These findings led Kety and associates to suggest that there may be a genetic factor in suicide independent or additive to depression, psychosis, or the other psychiatric disorders associated with suicide. They suggested that such a genetic factor for suicide may be involved in the control of impulsive behavior and that depression and stress may serve to trigger or foster impulsive suicidal behavior (Kety, 1986).

Conclusions

This review suggests that suicide, like so much else in psychiatry, tends to run in families. The clinical, Iowa, Amish, twin, and adoption studies show that a family history of suicide is associated with an increased risk of suicidal behavior. There are three possible reasons for this. First, the genetic factors in suicide may be the genetic transmission of psychiatric disorders per se—particularly affective disorders. Second, the Copenhagen adoption studies suggest that there may be a genetic factor for suicide that is additive to psychiatric disorders and that this genetic factor may be related to the control of impulsive behavior. Third, a family member who has committed suicide may serve as a role model for a disturbed individual.

(Auto)Aggression and CSF 5-HIAA in Depression and Schizophrenia

Herman M. van Praag, M.D., Ph.D.[1]

This paper is divided into two parts. The first part discusses methodological flaws in present day biological suicide research. In the first section previous observations are summarized. In the subsequent two sections new data are added. The second part describes a study adding new supportive evidence to the hypothesis relating aggression-regulation (or impulse control) to central serotonergic functioning.

Methodological Flaws in Biological Suicide Research

Previous Observations

In previous publications we called attention to some untenable assumptions on which present day biological suicide research is based. Most research is related to serotonin (5-hydroxytryptamine: 5-HT) and I will limit myself to that variable.

1. The observation that low CSF concentration of 5-hydroxyindoleacetic acid (5-HIAA) in depression is correlated with suicide attempt, in particular if committed with violent means, led to the conclusion of a relationship between decreased 5-HT metabolism and strong auto-destructive impulses. This conclusion is premature. The risk of violent suicide attempt appeared to be not evenly distributed over different forms of depression but to be increased in the group of endogenous depression (Major Depression, Melancholic type, according to DSM-III criteria) (van Praag & Plutchik, 1984). It is therefore impossible to decide whether low CSF 5-HIAA relates to violent suicide attempt or to the depression type in which the chance of that behavior happens to be increased.

2. The hypothesis that low CSF 5-HIAA relates to suicidal behavior rather than to the affective disorder as such, is based on low CSF 5-HIAA having been observed not only in depressed but also in non-depressed suicide attempters. The latter diagnosis however was based on *post*-suicidal assessment and is therefore unreliable. We demonstrated in a group of hospitalized suicide attempters that depression is extremely common in the 2 months prior to the attempt (van Praag, 1982), while during the first week of hospitalization the depression ratings drop significantly (van Praag & Plutchik, 1985). The diagnosis nondepressive suicide attempter therefore should be based on *pre*-suicidal assessment.

3. Method used in the suicide attempt has been used as a measure of strength of suicidal impulses. This is not justified. First, suicide method pertains to seriousness of the *attempt*, not to the seriousness of *intent*. These two variables should be assessed independently. Second, seriousness of attempt is not only determined by risk factors, among which method is the most significant one, but by the chance of being rescued as well. Weisman and Worden (1973) constructed a scale measuring lethality of the attempt as a risk/rescue ratio. We demonstrated that suicide attempters using violent means have the same risk/rescue scores as those using nonviolent means (van Praag et al., 1986). Obviously suicide method alone is not a reliable measure of lethality of the suicide attempt.

The Flaw of Equalizing Various Types of Suicidal Behaviors in Schizophrenia

5-HT studies in suicide have included three types of suicidal behavior: recent suicide attempt, life-time history of suicidal behavior with no recent attempt, and suicidal ideation. These behaviors have been regarded as equivalent and so have the biological data. They have simply been pooled and averaged. We obtained data making this procedure untenable.

---

[1] Department of Psychiatry, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY 10461.

In a group of schizophrenic patients with recent suicide attempts, prompted by "voices," but without an affective disorder, CSF 5-HIAA was found to be lowered compared to a matched group of schizophrenics without suicidal history and a non-psychiatric control group (van Praag, 1983). These observations were confirmed by Ninan et al. (1984). Subsequently we compared the findings in schizophrenics with recent suicide attempt with those obtained in two other groups: The first consisted of 13 schizophrenics with life-time history of at least 1 and on the average 1.6 suicide attempts but no recent attempts. The second group comprised 12 schizophrenics with suicidal ideation at the time of the lumbar puncture but no recent or past attempts. The various groups of patients were comparable in terms of symptomatology, age, and sex.

The only group of schizophrenics in which CSF 5-HIAA was lowered in comparison to the nonpsychiatric control group was the group with recent suicide attempts. In the others the concentrations were within normal limits (Figure 1).

We *concluded* that in schizophrenia low CSF 5-HIAA is related to recent suicide attempt.

The Flaw of Equalizing Various Types of Suicidal Behaviors in Depression

The situation is different in the group of affective disorders. We measured CSF 5-HIAA in 52 patients suffering from nonpsychotic major depression, melancholic type. Fifteen of them had attempted suicide recently, i.e., 3 to 7 days prior to the lumbar puncture. The second group comprised 19 patients with life-time history of at least 1 suicide attempt and on the average 1.9 suicide attempts. The third group, consisting of 18 patients, displayed suicidal ideation at the time of the lumbar puncture but had made no attempts either recently or in the past. All patients had been hospitalized.

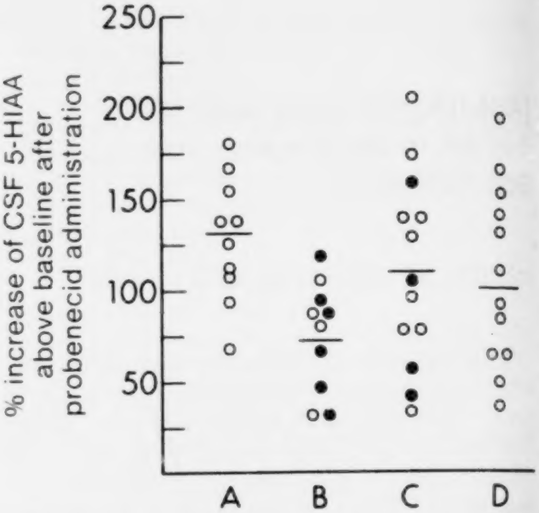

FIGURE 1. Percentage increase of post-probenecid CSF 5-HIAA above baseline concentration, in 4 groups of individuals. *Group A*: 10 controls without psychiatric symptoms or history. *Group B*: 10 schizophrenics with recent suicide attempts prompted by "voices." The lumbar puncture was carried out within 1 week after the attempt. *Group C*: 13 schizophrenics with life-time histories of suicide attempts but no recent attempts. *Group D*: 12 schizophrenics with suicidal ideation at the time of the lumbar puncture but no recent or past suicide attempts.

CSF 5-HIAA was measured before and 8 hours after the beginning of a probenecid load of 5 g/5 h.

In comparison with a nonpsychiatric control group, CSF 5-HIAA was lower in the group having made recent attempts and in the group with life-time histories of suicide attempts. In the group of patients with suicidal ideation, CSF 5-HIAA concentration was within normal limits (Figure 2).

We *concluded* that in affective disorder, low CSF 5-HIAA is apparently a trait marker related to increased risk of suicide. Moreover, it appears that suicidal ideation, intent, and attempt should be differentiated biologically, as they have to be, of course, in psychopathological terms. Attempts are obviously preceded or accompanied by suicidal ideation. Suicidal ideation on the other hand can occur without a marked drive to implement the idea. In other words, the intentional "load" of suicidal ideas does vary markedly.

The *general conclusion* is that in biological suicide research, recent attempt, life-time his-

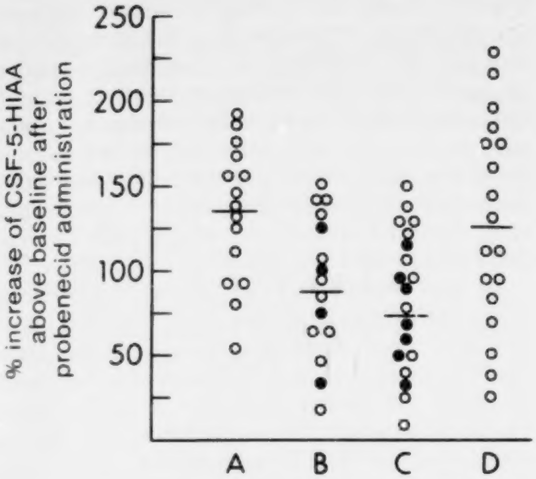

FIGURE 2. Percentage increase of post-probenecid CSF 5-HIAA above baseline concentration in 4 groups of individuals. *Group A*: 15 controls without psychiatric symptoms or history. *Group B*: 15 depressed patients with recent suicide attempts. Lumbar puncture was performed within 1 week after the attempt. *Group C*: 19 depressed patients with life-time history of suicide attempts but no recent attempts. *Group D*: 18 depressed patients with suicidal ideation at the time of the lumbar puncture but no recent or past suicide attempts. All depressed patients were suffering from major depression, melancholic type, according to DSM-III criteria.

CSF 5-HIAA was measured before and 8 hours after the beginning of a probenecid load of 5 g/5 h.

tory of suicide attempt, and suicidal ideation should be regarded and treated as separate categories.

New Evidence in Favor of a Relationship Between 5-HT and Aggression Regulation

Hypothesis

Low CSF 5-HIAA has been reported to occur in suicidal schizophrenic patients without affective disorder (Ninan et al., 1984; van Praag, 1983) as well as in nondepressed individuals with disregulated outward directed aggression (Bioulac et al., 1980; Brown et al., 1979, 1982; Lindberg et al., 1985; Linnoila et al., 1983). These findings prompted the hypothesis that lowered 5-HT metabolism is related not so much to depression or to suicidal behavior, but to disordered aggression regulation or disturbed impulse control. Based on this hypothesis, one would expect depressed patients with low CSF 5-HIAA, compared to similar patients with normal 5-HIAA levels, to display not only more suicidal behavior but more hostile behavior as well.

Methods

In order to verify this hypothesis, we compared 25 depressed patients with lowered CSF 5-HIAA and 25 depressed patients with normal 5-HIAA levels in terms of suicidal acts and acts of hostility in interpersonal functioning. CSF 5-HIAA was measured after probenecid administration (van Praag, 1977). 5-HIAA concentration was called lowered, if two standard deviations or more below the normal mean. The average number of previous admission for depression numbered 2.4 in the low 5-HIAA and 2.7 in normal 5-HIAA group. In both groups, the majority of patients was unipolar: 19 in the low 5-HIAA group, 17 in the normal-level-group.

By means of a semistructured interview, emotion-laden events, including hostility in interpersonal functioning which occurred in the preceding 6 months, were recorded. In addition, the occurrence of previous suicide attempts was explored. A suicide attempt was defined as any intentionally self-inflicted injury (including ingestion) with self-destructive intent. Only those attempts were counted that had led to medical intervention. Besides the patient, at least one "significant other" was interviewed. Finally, signs of hostility in interpersonal functioning during the interview were recorded.

Results

We were able to confirm previous observations indicating preponderance of suicide attempts in the low CSF 5-HIAA depressives compared to their normal 5-HIAA counterparts. In addition, the former group surpassed the latter in all signs of outward directed aggression that were studied (Table 1).

TABLE 1. Comparison of Patients With Major Depression, Melancholic Type (DSM–III) With Low Post-Probenecid CSF 5-HIAA ($n = 25$), and Those With Normal CSF 5-HIAA Post-Probenecid ($n = 25$).

Suicide Attempts and Signs of Interpersonal Hostility	$p \leq$
More suicide attempts	0.01
Greater number of contacts with police	0.05
Increased arguments with	
—relatives	0.05
—spouse	0.01
—colleagues	0.05
—friends	0.05
More hostility at interview	0.05
Impaired employment history (arguments)	0.05

Discussion and Conclusion

The high concordance of inward and outward directed aggression has been established in purely psychopathological studies as well. Weissman et al. (1973), comparing a group of suicide attempters with a group of depressed patients, found increased hostility in the suicide group to be the single most important distinguishing characteristic between the two groups. Another case in point is the high incidence of suicide in murderers amounting to more than 30 percent in some European countries (West, 1965). Psychoanalysts of old, of course, underlined the trivariate relationship between aggression, depression, and suicide (Freud, 1956). In conformity with our findings, Rydin et al. (1982) reported that depressed patients with low CSF 5-HIAA showed on Rorschach testing more hostility than comparable patients with normal 5-HIAA.

In conclusion, in depressives with low post-probenecid CSF 5-HIAA, suicide attempt and outward directed aggression are more frequent than in normal CSF 5-HIAA depressives. These data support the hypothesis of diminished central 5-HT metabolism being related to disordered aggression regulation or diminished impulse control.

Summary

Two issues are being discussed. In the first part of this paper methodological shortcomings of present day biological suicide research are discussed. Previous data are summarized and one flaw is added, i.e., the inadmissability of putting on a par different forms of suicidal behavior—such as suicidal ideation, recent suicide attempt and life-time history of suicide attempts—and generalizing about the biological findings. Evidence is presented that these behaviors are biologically heterogeneous, as they are psychopathologically.

In the second part evidence is presented that depressives with low CSF 5-HIAA show not only more signs of suicidal behavior than their normal 5-HIAA counterparts but more evidence of hostile behavior as well. These findings support the hypothesis that diminished central 5-HT metabolism and disordered aggression regulation (or impulse control) are interrelated, a hypothesis with which we have dealt in more detail elsewhere (van Praag, in press).

Acquired Immunodeficiency Syndrome (AIDS): Neuropsychologic and Psychoimmunologic Aspects

Co-Chairs:

T. Peter Bridge, M.D
Office of the Administrator
Alcohol, Drug Abuse, and Mental Health Administration
Rockville, MD 20857

Allan F. Mirsky, Ph.D.
National Institute of Mental Health
Bethesda, MD 20892

Introduction

T. Peter Bridge, M.D.,[1] and Donald I. Macdonald, M.D.[1]

Although considerable public preoccupation with the Acquired Immunodeficiency Syndrome (AIDS) presently exists, inclusion of a panel on AIDS by the American College of Neuropsychopharmacology reflects our recent awareness of the neuropsychiatric aspects of this illness. As we would expect, any fatal illness such as AIDS would have psychologic parameters. Some of these are unique to AIDS and have been addressed elsewhere (Holland & Tross, in press). What the papers in this panel demonstrate, however, is that neuropsychologic consequences, presumably secondary to a direct viral infection of the brain by the Human Lymphotropic Virus, Type III (HTLV-III) (Levy et al., 1985; Ho et al., 1985; Resnick et al., 1985), the etiologic agent for AIDS, are also present. As background, then, for the papers in this panel three points need to be stated:

1) AIDS is a medical problem of the highest priority to the American medical research community;

2) AIDS is an illness whose sequelae are likely to remain with us for a considerable period of time;

3) AIDS is an illness presenting the fields of neuroscience and behavioral research with challenges and opportunities compelling to pursue.

Few remain to be convinced of the importance of AIDS. The epidemiologic facts speak for themselves:

- 16,000 cases of AIDS in the United States have been reported to the Centers for Disease Control as of January 1986, with the number of cases doubling every 6 to 12 months in many areas. One half of these cases are already dead. No one is known to have recovered from AIDS (CDC Update: AIDS—USA, 1986).
- Estimates are that as many as 1 million people have been infected by HTLV-III (Curran et al., 1985).
- Current estimates are that at least 10 percent of those infected with HTLV-III will develop the full blown AIDS diagnosis during the 5 or more years of incubation period (Curran et al., 1985). This could translate to 100,000 dead by the end of this decade.

---

[1] Office of the Administrator, Alcohol, Drug Abuse and Mental Health Administration, Rockville, MD 20857.

- Among some high risk groups in metropolitan areas, prevalence rates for infection by HTLV-III approach 60 to 70 percent sampled (Fauci et al., 1985; Marmor et al., 1984).
- While AIDS has been an illness appearing first in certain high risk groups in this country [sexually active gay and bisexual men, intravenous (i.v.) drug users, recipients of blood products contaminated with HTLV-III, and sexual partners or infants born to these groups] (Curran et al., 1985), the likelihood of its spread to other groups (i.e., sexually active, non-i.v. drug using heterosexuals) in this country remains unknown.
- Data from central Africa, where the AIDS epidemic hypothetically originated, make clear the point that transmission of the virus among sexually active persons is male to male, male to female, and female to male (Fauci et al., 1985).

These facts make the point that AIDS is a present public health imperative. What data do we have that speak to whether AIDS will remain an imperative? It would be an all too easy leap of faith to observe that medical researchers have made extraordinary progress since AIDS was first described in late 1981. We know the etiologic agent for the illness (Fauci et al., 1985). We have serologic screening tests that can detect blood products contaminated with HTLV-III as well as processes to render clotting factors free from the virus (Curran et al., 1985). In 3 years medical research has accomplished what took decades with prior infectious illnesses. Unfortunately, the next phases of medical research do not appear likely to move so quickly.

- Antibodies to HTLV-III detected in enzyme linked immunosorbent assay or the ELISA test do not neutralize the virus (Fauci et al., 1985).
- Characteristic of the retroviruses, to which HTLV-III belongs, is the capacity to mutate frequently and spontaneously. Most of the mutations occur in the protein envelope surrounding the virus, to which vaccines are normally developed. To date more than 200 separate isolates of HTLV-III have been made (Benn et al., 1985). There may be, however, constant segments on the viral envelope to which a vaccine might be developed (Gallo, 1985).
- There are no currently effective treatments for AIDS. Treatment regimens must address both antiviral approaches as well as restoring immune function. Antiviral agents, while effective in reducing viral counts in AIDS patients, are extremely toxic and require ongoing administration to continue their antiviral action (Fauci et al., 1984). Effective immunostimulant treatments do not presently exist, although recent findings with Interleukin-2 may prove useful for AIDS patients eventually (Lane et al., 1984).

One does not wish to sell short the possibility of dramatic advances in the treatment and prevention of AIDS. They occur and hopefully they will happen and happen soon for those infected with HTLV-III. Our colleagues in cancer and immunologic research caution us, however, not to expect either effective vaccines or treatments soon (Gallo, 1985).

The papers in this panel make the point that neuropsychiatric symptoms—behavioral, affective, cognitive, and motoric—are part of the AIDS picture. Of course, there are sample to sample variations, but a consistent picture nonetheless emerges. Not only is there evidence of a global, and to date untreatable, brain disease present in AIDS patients, but this may also be one of the most critical issues determining choices in clinical care. The course of AIDS is characterized by intermittant infections, some of which are amenable to medical intervention. Between episodes of infection, these patients generally remain outside the hospital. When cognitive impairment appears, decisions about chronic institutionalization are generally made. Future research must address the issue of cognitive impairment from HTLV-III infection. Efficacious treatment for the immune defects in AIDS which do not act in the central nervous system (CNS) will likely result in a population of healthy, but demented, AIDS patients. As papers in this panel indicate, neuroreceptor and neurotransmitter research offer a most intriguing opportunity for AIDS research. At this point we must conclude that HTLV-III exhibits tissue specificity both for the T4 lymphocyte, perhaps the monocyte, and white matter in the CNS. Speculatively, data presented in these papers might lead us to consider the role of neuroreceptor and neurotransmitter research in the development of effective treatment and prevention strategies for AIDS.

While the development of vaccines and antiviral therapies generally are outside the purview of neuropsychopharmacologic research, many agents which have immunosuppressant actions do typically fall within this research area. We do need to learn much more about the role of cofactors in the progress of a viral illness such as AIDS. Various psychoactive agents including alcohol, nitrites, marijuana, heroin, as well as stressful life experience and affective illness have all been reported to be associated with immunosuppression (Morahan et al., 1979; Orangio et al., 1983; MacGregor & Gluckman, 1979; Ader, 1981). In an illness marked by progressive health deterioration secondary to impaired immunoresponsivity, we might speculate that agents which worsen immune function would hasten the course of this illness. More speculative would be the extent of such an effect or whether compromised immune function observed in many members of AIDS high risk groups is causally linked to the onset of HTLV-III infection. Research needs to replace speculation.

AIDS research represents one example of many illnesses which fall at the intersection of neuroscience, immunology, and endocrinology. Both predisposition and illness outcome may be expressed in behavioral terms. These are concepts and methodologies familiar to those in the field of neuropsychopharmacology. The progress that has been made to date in AIDS research is the result of rapid utilization of technologies already in place. The application of other technologies and the development of new technologies are needed to move the field of AIDS research forward. It is time to make use of the neuroscience and behavioral science technologies to advance AIDS research.

Psychosocial Aspects of AIDS Risk

David G. Ostrow, M.D., Ph.D.,[1] Jill Joseph, Ph.D.,[2] Andrew Monjan, Ph.D.,[3] Ronald Kessler, Ph.D.,[4] Carol Emmons, Ph.D.,[2] John Phair, M.D.,[5] Robin Fox, M.S.,[6] Lawrence Kingsley, D.P.H.,[7] Janice Dudley, D.P.H.,[8] Joan S. Chmiel, Ph.D.,[9] and Mark Van Raden, M.S.[10]

Introduction

Since its discovery in 1981 (Centers for Disease Control, 1981, 1981a) there have been approximately 20,000 cases of acquired immunodeficiency syndrome (AIDS) reported to the Centers for Disease Control (Centers for Disease Control, 1986). Central to all considerations of this usually fatal syndrome has been the concentration of cases in several specific risk groups, most notably homosexual or bisexual men (73 percent) and intravenous drug abusers (17 percent). Given the recency of AIDS and its varied clinical presentations and course, the National Institutes of Health (NIH) in collaboration with the National Cancer Institute (NCI) in 1983 set about the establishment of a series of natural history and epidemiology studies of immune function in homosexually active men in four cities including those with both very high and relatively low AIDS incidence rates. The Multicenter AIDS Cohort Study (MACS), as that cooperative research program has come to be known, began to enroll subjects early in 1984 in Los Angeles, Chicago, Pittsburgh, and Baltimore. The goal of the MACS is to investigate, in a relatively large cohort of homosexual men, the natural history of infections and other problems leading to the development of AIDS with particular attention to the sequelae of HTLV-III infection, early medical manifestations of AIDS, and transmissability of HTLV-III within subpopulations of the cohort. However, we also are focusing on the identification of potential cofactors or modulators associated both with the risk of developing HTLV-III infection once exposed to the virus and the subsequent development of specific medical endpoints such as AIDS and AIDS related illness in an individual. Between April of 1984 and March 1985, the full MACS cohort of over 1,000 men in each MACS center were enrolled and subjected to a medical history interview, physical examination, immunological and viral laboratory testing, specimen acquisition, and lengthy epidemiological investigation. Since then, each subject has returned on a 6-month basis for follow-up evaluation. In addition, those individuals showing recent seroconversion to a positive HTLV-III antibody test are currently being enrolled in a quarterly examination protocol to determine the sequence of immunological consequences of HTLV-III infection and, by attempting to isolate virus from various bodily tissues, to determine more precisely the infectivity and routes of transmission of the HTLV-III virus. Preliminary retrospective findings from the baseline MACS protocol have been summarized elsewhere (Multicenter AIDS Cohort Study, 1985). However, it is important to note that approximately 40 percent of the MACS cohort was HTLV-III antibody positive at baseline. The degree of seropositivity correlated with

clinical status: in asymptomatic men with no extrainguinal lymphadenopathy or other signs or symptoms of AIDS related complex (ARC), the positivity rate was only 20 percent. In contrast, in subjects with lymphadenopathy with or without other constitutional symptoms of ARC, the positivity rate ranged from 65 to 85 percent.

Methods

Because of the enormous psychological and social consequences accompanying being at risk for AIDS and the belief that psychological and other factors may be involved in determining disease course following HTLV-III infection, a group of investigators from the University of Michigan and the Chicago MACS team have undertaken a psychosocial study of the participants in the Chicago cohort of the MACS study. The "Coping and Change" study has as its principal objectives the determination of the psychological and social characteristics of the AIDS crisis as experienced and perceived by homosexual men participating in the MACS. We are assessing, using previously validated self-administered questionnaires, a broad set of psychosocial variables, including: perceived risk of AIDS, causal attributions, personality, lifestyle, life events, social support networks, and coping mechanisms (Joseph et al., 1984). As outcomes, we are studying behaviors which may place one at increased risk for acquiring HTLV-III infection, social functioning in a variety of settings, and various measures of psychological distress and symptomatology (Joseph et al., 1985). In addition, we are ultimately interested in examining the relationship between these psychological measures, immunological changes and clinical outcomes (AIDS, ARC, lymphadenopathy) taking place both independently and as the result of HTLV-III infection in the study population.

Results

The basic characteristics of our population are presented in Table 1. Our subjects are upper middle class, predominantly white, with at least 4 years of college and postgraduate education. The majority of subjects described themselves "exclusively homosexual" on the Kinsey sexual preference scale (Kinsey et al., 1948) and at least 20 percent have had a close sexual or social contact with an AIDS patient. An overview of the extent to which specific high-risk sexual behaviors were reported to have changed in our cohort at the time of baseline evaluation is shown in Table 2. We must caution that subsequent waves of analysis are indicating further behavioral change. We focus here on three specific high-risk behaviors, namely receptive oral-genital, receptive anal-genital, and insertive oral-anal intercourse. From 11 to 60 percent of subjects ever having performed a specific sexual behavior reported not having engaged in that behavior during the month prior to baseline evaluation. Of the remaining individuals, approximately half avoided exchange of ejaculate during oral-genital intercourse in line with recommended sexual practices modifications for the avoidance of transmission of HTLV-III infection. These modifications of either condom use or avoidance of ejaculation were less frequently used by persons continuing to engage in receptive anal intercourse. Pilot data indicated that this period of 1 month prior to questionnaire completion provides a valid and accurately remembered indication of current sexual activity.

The difficulty of completely eliminating high-risk sexual behavior is also indicated by the response to questions directly asking the subject to assess the extent and significance of their sexual behavioral changes. While three-quarters of our subjects replied that they feel they have changed a specific aspect

*Modification defined as behaviors which potentially interrupt exposure to semen such as condom use or withdrawal before ejaculation

of their behavior and made an effort to reduce the total number of sexual partners, only one-half of the cohort at baseline felt that they had changed "medically important things and been fairly consistent in those changes." This pattern of some behavioral change coupled with difficulty in maintaining that change is what we would expect for relatively established sexual behaviors for which rapid elimination is urged in order to reduce the risk of disease, a largely negative inducement. This is shown when we look at the degree of psychological stress associated with these changes. Subjects reported modest amounts of perceived stress in terms of making those behavioral changes that they had already accomplished. While the thought of eliminating the most frequently persistent behavior, oral-genital intercourse, was associated with the highest level of anticipated stress, over half of the subjects rated the anticipated stress of making further changes which would bring them into a low- or no-risk situation as either very stressful or fairly stressful.

Further examination of our data indicates that the pattern of behavioral change is creating subgroups within our cohorts. When we look at average number of sexual partners or frequency of any specific activity, we see a very skewed distribution with the mean numbers much higher than the mode (e.g., 6.0 vs. 1.0). Examination of the actual distribution of numbers of sexual partners (Figure 1) very clearly shows that the majority of our subjects have reduced the number of sexual contacts to relatively low numbers whereas a few subjects remain with very high numbers of sexual partners indicating two distinct patterns of sexual behavior in our cohort.

Examination of the reasons given for continued high-risk sexual behavior indicates several patterns of rationalization for persistent high risk behavior. Most frequent (75 to 80 percent) is the assertion that the individual feels he is at low risk by "limiting the number of sexual partners." However, almost as frequently given are statements that the activity is too enjoyable to stop despite prior resolutions. Between 30 to 40 percent also report that peer pressure and expectations by sexual partners are determining factors in the continuation of that activity. Finally, 25 percent of the cohort expresses some form of a sense of invulnerability—either they do not believe that their sexual activities place them at risk or that they believe that many more sexual exposures than they are having are necessary to develop AIDS. This is in spite of information given to the cohort stating very clearly that any sexual contact involving the exchange of bodily fluids places one at high risk of transmitting or contracting infection.

We have just begun to examine the psychological outcomes associated with the various behavioral and social consequences of being at risk for AIDS. We here present some ini-

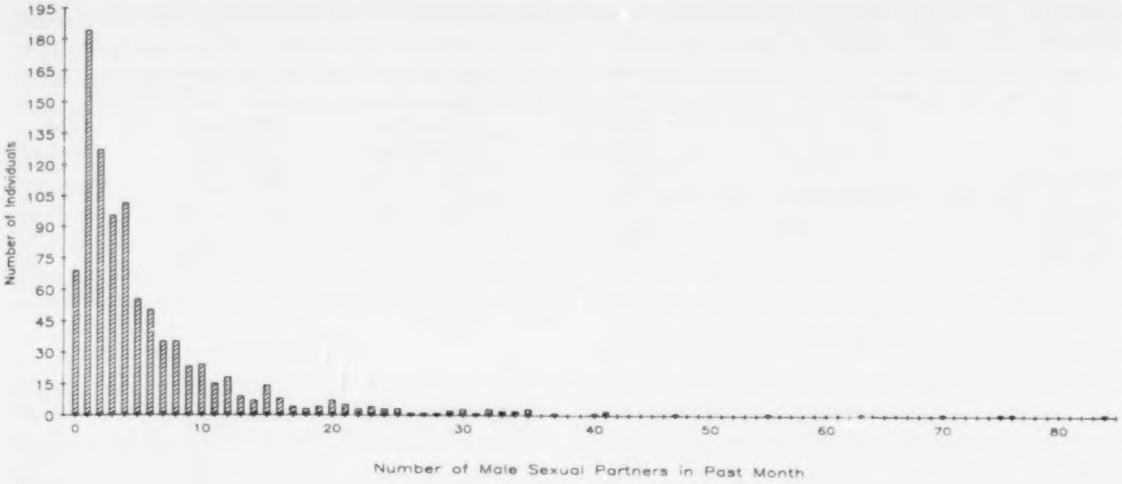

FIGURE 1

tial data utilizing the Center for Epidemiological Studies Depression Scale (CES-D) (Radloff, 1977) which has been and continues to be administered to all 5,000 members of the MACS cohort in all four cities. The baseline CES-D data indicates a remarkable degree of consistency in the patterns of responses in our cohorts between the four cities, indicating that at least in terms of this very broad measure of psychological function there is little difference between the cohorts whether they reside in Los Angeles, Chicago, Pittsburgh, or Baltimore. In comparing the overall responses of the MACS cohort to a published study of 680 married men (Ross & Mirowsky, 1984) we see that the former is more highly educated (16.3 vs. 13.1 years) and has a modest elevation in total CES-D score (9.75 vs. 8.88, $p < .01$). Table 3 shows the distribution of CES-D scores in our population as compared to the Ross and Mirowsky sample of married men with the MACS population separated on the basis of whether they were HTLV-III antibody negative or positive at the time of evaluation. Our subjects are elevated primarily in the depressed affect subscale of the CES-D when compared to the married male cohort. Differences between HTLV-III negative and positive members of the MACS cohort are seen only in the depressed affect and enervation subscales of the CES-D. Examination of the specific items endorsed more frequently by HTLV-III positive subjects in our cohort indicated a cluster of items (feeling blue, difficulty concentrating, poor sleep, lack of energy, and difficulty communicating to others) which suggested a higher level of anergy in HTLV-III exposed individuals. These symptoms are similar to those found by investigators looking at AIDS patients with CNS complications of HTLV-III infection (Perry & Tross, 1984). Univariate analysis of the relationship between a broad set of predictor variables (sex-

*$p < .01$. **$p < .001$.

ual and drug use behaviors, health, history and physical examination findings) revealed that self-reported lymphadenopathy was strongly associated with increased CES-D scores.

The effect of perceived lymphadenopathy on self-reported depression and anergy can be seen in Table 4 where CES-D scores are given for the eight subgroups according to HTLV-III serology status, lymphadenopathy observed on physical exam, and perceived lymphadenopathy. In almost all comparisons, subjects who denied the presence of swollen lymph nodes had CES-D scores as low as persons without actual and perceived lymphadenopathy. While the highest CES-D scores were obtained in seronegative subjects with recognized lymphadenopathy, in the seropositive group persons who reported lymphadenopathy which was not confirmed on physical examination had higher CES-D scores than those with examiner confirmed lymphadenopathy ($p < .05$). It is interesting that the three specific symptoms which were most elevated in healthy seropositive subjects who worried that they had lymphadenopathy were restless sleep, fearfulness, and "difficulty getting going."

The final data presented in Figure 2 show the relationship between the pattern of perception and actual presence of lymphadenopathy and an overall measure of cellular immune function, the T-helper: T-suppressor lymphocyte ratio. The higher the T-helper:T-suppressor ratio, the more likely that an individual has an adequately functioning cellular immune system. Looking at the left side of the figure, there was an effect of perception of lymphadenopathy in HTLV-III seronegative individuals with those perceiving themselves as having lymphadenopathy having significantly lower helper:suppressor ratios than those who did not ($p < .001$). However in the HTLV-III antibody positive portion of our cohort (right side of figure) only the effect of HTLV-III infection on this cellular immune parameter is seen. Any differences based on perception or presence of lymph nodes seen in the antibody negative group are lost once the overriding effect of this virus on the helper:suppressor ratio has taken place. These findings suggest that if we are to look for psychoimmunological correlates in cohorts at risk of AIDS, we must look for situations where we can factor out the overwhelming effect of virus infection from the more modest effects of psychological functioning upon the immune system.

In conclusion, this overview of the psychological and behavioral consequences of AIDS risk illustrates some of the profound changes taking place in the male homosexual population as the result of this health crisis. Coupled with the psychological consequences of the threat of developing AIDS are the secondary stresses of the behavioral change itself and the social isolation and stigmatization of the

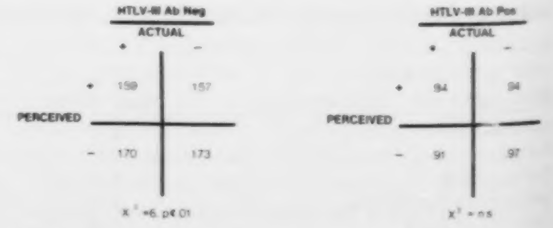

FIGURE 2. T-helper/T-suppressor ratio and lymphadenopathy status.

disease. We must now add the effects of CNS HTLV-III infection to the list of factors potentially contributing to the depression and anergy seen in our study population (Shaw et al., 1985; Ho et al., 1985). Carefully designed prospective examinations of psychological, cognitive, and neurological functioning in persons infected with HTLV-III are necessary if we are to sort out the relative contributions of these various factors to the overall mental health impact of AIDS.

Neuropsychiatric Aspects of AIDS

Russell T. Joffe, M.D.,[1] David R. Rubinow, M.D., [2] Kathleen Squillace, B.S.,[3] Clifford H. Lane, M.D.,[4] Connie C. Duncan, Ph.D.,[3] and Anthony S. Fauci, M.D.[4]

Neurological complications are a commonly observed feature of acquired immune deficiency syndrome (AIDS) (Snider et al., 1983). Several case reports have described AIDS patients, particularly those with subacute encephalitis, who present with clinical manifestations of a rapidly progressive delirium or dementia (Ochitill et al., 1984; Loewenstein & Sharfstein, 1983–84; Snider et al., 1983). There have also been reports of adjustment disorders with altered mood in patients after they have been diagnosed with AIDS (Ochitill et al., 1984). However, these case studies describe either patients with gross central nervous system dysfunction or patients who have been referred for psychiatric consultation specifically because of behavioral disorders or alteration in mental state. Therefore, very little is known about the neuropsychiatric characteristics of patients with AIDS unselected for psychiatric disorders or neurological complications.

In this paper, we report preliminary data from a systematic investigation of the neuropsychological functioning and occurrence of psychiatric disorders in a group of AIDS patients who had no clinical evidence of neurological disease.

Subjects

Thirteen male homosexual AIDS patients, who were electively admitted to the National Institute of Allergy and Infectious Disease for various study protocols, gave oral and written informed consent to participate in this study. All subjects were free of acute illness and had no clinical or laboratory evidence of systemic infection; three patients did have residual Kaposi skin lesions. Most patients were medication-free, and none had recently received psychoactive drugs.

Ten males were recruited by the volunteer office at the National Institutes of Health from the local homosexual community to serve as a control group. All were screened clinically and by routine laboratory tests for the absence of medical illness.

Method

A standardized psychiatric interview, using a modified version of the Schedule for Affective Disorders and Schizophrenia—Lifetime Version (SADS—L) (Spitzer & Endicott, 1978*a*) was performed on 10 patients and all the controls. Psychiatric diagnoses for the subjects and their first-degree relatives were derived from the interview according to Research Diagnostic Criteria (RDC) (Spitzer et al., 1978*b*). All subjects, at the time of interview, completed the Beck Depression Inventory (Beck et al., 1961) and the Symptom Checklist 90—Revised (SCL-90R) (Derogatis, 1984).

A neuropsychological test battery that evaluated general intelligence as well as specific cognitive functions was performed on all patients and controls. The specific cognitive functions tested include abstraction and categorization, visual-spatial organization and visual-motor performance, and attention and concentration. These tests included:

1) The Wechsler Adult Intelligence Scale—Revised (WAIS—R),
2) Trail Making Test,
3) Rey Osterreith Complex Figure Test,
4) Halstead Category Test,
5) Wisconsin Card Sort,

12) Babcock Story Recall Test,
13) Harris Hand Dominance Test.

In addition a personality profile was obtained with the Minnesota Multiphasic Personality Inventory (MMPI).

Details of these tests and their references are available from the authors on request.

Statistical analysis was by group *t*-tests and Fisher Exact Tests.

Results

a) *Psychiatric Interview.* Three patients (1—substance abuse disorder, 2—adjustment disorder with depressed mood) and three controls (adjustment disorders with mixed mood) fulfilled RDC criteria for current psychiatric disorders. Eight patients and six controls had a history of past psychiatric disorder (p = NS, Fisher Exact Test). Past major depressive disorder tended to be more common in patients (5 of 10) than controls (1 of 10) ($p = 0.07$, Fisher Exact Test). However, a history of past adjustment disorder tended to be significantly more common in controls (5 of 10) than patients (1 of 10) ($p = 0.07$, Fisher Exact Test). A family history of psychiatric disorder was evident in four patients and four controls.

AIDS patients had significantly higher scores on the Beck Depression Inventory than controls (14.4 ± 2.7 vs. 4.9 ± 1.2, $t = 2.90$, $p < .02$). There was also a nonsignificant trend for patients to have higher scores on the Depression Scale of the SCL-90R (1.16 ± .04 vs. 0.33 ± 0.2, $t = 2.01$, $p < .1$). However, only the two patients with adjustment disorder with depressed mood scored in the depressed range (more than 15) (Beck et al., 1961) on the Beck Depression Inventory.

b) *Neuropsychological Test Battery.* Patients and controls were well-matched for age (34.8 ± 7.0 years vs. 35.3 ± 6.9 years, $t = 0.20$, $df = 21$, p = NS), years of education (14.2 ± 0.6 years vs. 14.3 ± 0.7 years, $t = 0.02$, $df = 21$, p = NS), and right handedness (11 patients and 9 controls, p = NS, Fisher Exact Test).

All mean scores on the WAIS-R were within the normal range. However, AIDS patients had significantly lower scores than controls on Full Scale IQ ($t = 2.26$, $p < .05$), and Verbal IQ ($t = 2.30$, $p < .05$). (*See* Table 1.) There was a trend for performance IQ to be lower in AIDS patients as compared with controls ($t = -1.65$, $p < .1$). AIDS patients also scored significantly lower than controls on the following subtests: Vocabulary ($t = -3.05$, $p < .01$), Similarities ($t = -2.45$, $p < .05$), and Digit Symbol ($t = -2.93$, $p < .05$).

On the Halstead Category Test, patients, as compared with controls, had a significantly higher mean number of errors ($t = 2.61$, $p < .05$). Moreover, 5 of 8 patients as compared with 2 of 10 controls scored above 50, the upper limit of normal performance ($p = 0.07$, Fisher Exact Test). On the other hand, no difference was noted between patients and controls in either mean or perseverative error scores on the Wisconsin Card Sort, a test of categorization and abstraction that is particularly sensitive to frontal lobe dysfunction.

On the Cancellation Tests, timed vigilance and attention tasks which also measure motor skills, patients completed significantly fewer items and had significantly fewer correct responses than controls on each of the three sections, although no significant difference in number of errors committed was observed. On the CPT, however, a test of sustained visual attention, no significant difference was observed between subjects and controls in variables measured, including percentage of correct responses, omission errors, commission errors, and mean reaction time. Furthermore, AIDS patients did not differ from controls in their performance on the other test of attention and concentration, the Stroop Color-Word Test.

AIDS patients took significantly longer than controls to complete Trial B of the Trail Making Test ($t = 2.69$, $p < .05$). However, their mean score was within the normal range on Trial B, and there was no difference in performance on Trial A between patients and controls. The Trail Making Test is a measure of visual-conceptual and motor performance.

TABLE 1. Significant Differences in Neuropsychological Test Scores Between AIDS Patients and Controls.

Test	Description	AIDS Patients[1]	Controls	t^2	df

In contrast to the other tests, patients did better than controls on the copying but not the recall part of the Rey Osterreith Complex Figure Test, a test of visual-spatial organization. Patients as compared with controls had a higher percentile score on the copying component ($t = 2.12, p < .05$), but there was no significant difference in scores on immediate and 40 minute recall.

On all memory tests, The Wechsler Memory Scale, Buschke and Babcock, as well as the Raven's Progressive Matrices, the performance of patients was not different from that of controls and all mean scores were within normal limits.

On the MMPI, AIDS patients, as compared with controls, had significantly higher scores on only the hysteria (Hs) scale ($t = 3.63, p < .01$), although they tended to also have a higher score on the hypochondriasis (Hy) scale ($t = 1.99, p < .1$). With the exception of the hysteria and hypochondriasis scales, which were markedly elevated in the patients, scores for both subjects and controls were similar to those previously reported for homosexuals (Horstman, 1975).

Discussion

Our data show that a group of AIDS patients unselected for psychiatric morbidity are more likely to have a history of past depressive illness than a group of medically well homosexual controls. The implications of this finding are uncertain. However, depression has been associated with several measures of immune system dysfunction, and depressed patients have been reported to have increased susceptibility to cancer, infections, and allergic disorders, all of which may be associated with disorders of immune function (Kronfol et al., 1983). Speculation must clearly be limited pending replication of this observation in a larger group of patients.

Our neuropsychological test data show that AIDS patients, in the absence of evidence of active neurological disease, when compared with medically well homosexual controls matched for age and educational level, show reduced levels of general intellectual and specific cognitive function.

On the WAIS-R, the significantly lower Full Scale and Verbal IQ and the trend towards significantly lower Performance IQ is suggestive of lower general cerebral functioning in the AIDS patients compared with controls. In addition, the significantly reduced Similarities and Digit-Symbol subtest scores in the patients are consistent with other evidence of diffuse cerebral impairment (Lezak & Glaudin, 1972). On the other hand, the significantly reduced Vocabulary subtest score in the AIDS patients may be more consistent with lateralized, particularly dominant hemisphere, cerebral dysfunction, as this subtest is usually the least affected by diffuse brain dysfunction or psychiatric disorders (Lezak & Glaudin, 1972). Therefore, the Vocabulary subtest data, if not due to a sampling error, may suggest a dominant hemisphere dysfunction in the AIDS patients, and the significantly reduced Similarities subtest score, while suggestive of diffuse cerebral dysfunction, may also be consistent with such a reduction in dominant hemisphere function (Lezak & Glaudin, 1972).

The significantly fewer total and correct items on the Cancellation Test, the significantly longer time to complete part B of the Trail Making Test, and the reduced Digit-Symbol subtest scores in the AIDS patients as compared with controls are all suggestive of a slowing of visual-motor performance. On the other hand, on the CPT, also a timed test, no difference between patient and control groups were evident. However, the CPT differs from the Trail Making Test, Cancellation Test and Digit Symbol subtest in that items are presented at a steady rate determined by the test, not the subject, whereas the latter three tests are self-paced with speed rewarded. It is, therefore, possible that impairment on these tests may represent diminished motivation.

The mean score on the Halstead Category Test was in the abnormal range in the AIDS patients as compared with the controls. The abnormal Halstead Test scores are suggestive of abnormalities of abstraction and conceptualization as well as being a sensitive measure of general brain dysfunction (Halstead, 1947).

The significance of our neuropsychological data is unclear. It is possible that depressed mood could account for these abnormal findings, as depression can have an effect on all these tests, particularly on the more effortful, self-paced tasks such as the Cancellation Test, Trail Making Test, and Digit Symbol subtest. However, when the data were reanalyzed excluding the two patients who scored in the depressed range on the Beck Depression Inventory, significant differences between patients and controls remained the same. Obviously, reduced motivation may exist despite the absence of clinically evident depression.

The absence of differences in memory tests between the AIDS patients and controls suggests that there was preservation of memory function in the patient group despite evidence of general and specific cognitive dysfunction.

With the exception of the hysteria and hypochondriasis scales, the scores on the MMPI did not differ significantly between patient and control groups. Furthermore, the scores in both groups were not substantially different from those reported for both homosexual and heterosexual males (Horstman, 1975). The significantly elevated scores on the hysteria and the nonsignificantly elevated hypochondriasis and depression scales in the AIDS patients are similar to the elevated "neurotic triad" which has been described in neurological patients with no psychiatric disease (Lezak & Glaudin, 1972).

Our preliminary data, although requiring replication in larger samples, are similar to the data reported by Tross and Holland in this volume. Nonetheless, longitudinal, prospective studies of cognitive functioning in a larger group of AIDS patients are necessary to ascertain whether general cerebral and dominant hemisphere function in AIDS patients is impaired and if it progressively declines over the course of the illness. Further studies should also include a non-neurological medically ill control group to clarify whether the neuropsychological impairments are specific to AIDS or to medical illness in general. Finally, although the number of *t*-

tests performed in our data analysis increased the likelihood of observing significant differences on the basis of chance, the significant differences observed were almost uniformly (15/16) in the direction of greater cognitive impairment in the patients, thus suggesting that AIDS patients do perform more poorly than controls on at least some cognitive measures.

In conclusion, our findings suggest that AIDS patients, in the absence of clinical evidence of neurological complications, as compared with medically well homosexual controls, are more likely to have a history of past major depressive illness and to have evidence of reduced general and specific cognitive function. Our data are intriguing in the light of the recent report that the HTLV-III virus is trophic to brain tissue, perhaps in a site-specific manner (Shaw et al., 1985). Our findings, although preliminary, raise some important clinical issues. These include the potential prognostic importance of these neuropsychological findings, the extent to which their longitudinal course may parallel that of the illness, their potential reversibility if an effective treatment for AIDS is found, and their impact on the long-term rehabilitation of the AIDS patients. Further study of neuropsychological function in HTLV-III positive patients, with and without AIDS, will also advance our understanding of the relationship between immune system and central nervous system dysfunction.

Localization of the T4 Antigen/AIDS Virus Receptor in Monkey and Rat Brain: Prominence in Cortical Regions

Joanna M. Hill, Ph.D.,[1] William L. Farrar, Ph.D.,[2] and Candace B. Pert, Ph.D.[1]

Introduction

The acquired immune deficiency syndrome (AIDS) is a recently described cellular immunodeficiency disorder which is characterized by malignancies and opportunistic infections with a variety of pathogens (Gottlieb et al., 1981; Masur et al., 1981; Siegal et al., 1981).

Central nervous system involvement, as evidenced by intellectual and cognitive impairment (Joffe et al., 1986), language disorders, movement dysfunction, stroke symptoms (Wolcott et al., 1986), and delirium and dementia (Snider et al., 1983; Loewenstein and Sharfstein, 1983–84), is a common feature in AIDS patients and neuropathological complications, such as encephalitis, neoplasms, and vascular lesions, frequently occur (Snider et al., 1983).

The retrovirus, HTLV-III/LAV (human T lymphotropic virus type III/lymphadenopathy virus) has been implicated as the causative agent in AIDS (Barre-Sinoussi et al., 1983; Popovic et al., 1984; Levy et al., 1984). AIDS infection is found to deplete the helper/inducer T lymphocyte subset which is characterized by the presence of the T4 surface antigen (Klatzmann et al., 1984). HTLV-III/LAV binding, absorption, and replication in human (Klatzmann et al., 1985; McDougal et al., 1985; Dalgleish et al., 1985) and squirrel monkey (Ruscetti et al., in press) T cells can be inhibited by anti-T4 mab; therefore, it appears that the T4 antigen complex acts as the viral entry protein or receptor.

Spurred by the realization that immune cells and brain cells frequently share common antigens (Pert et al., 1985), as well as the report that HTLV-III/LAV associated retrovirus has been isolated from brain tissue (Shaw et al., 1985), we recently demonstrated that similar T4 antigen structures are present on lymphoid and brain structures (Ruscetti et al., in press). In contrast to the suggestion that the neurological/psychiatric symptoms of AIDS are the secondary results of opportunistic infections and/or reactions to the disease, we have suggested that the virus interacts with brain cells via an entry protein (receptor) shared in common with T cells, thus directly causing psychiatric and neuropathological dysfunctions (Ruscetti et al., in press).

Using a novel autoradiographic method, the present study visualizes the distribution of the T4 antigen/AIDS virus receptor on sections of squirrel monkey brain. We now also report that the T4 antigen is present on rat brain and is distributed in a manner analogous to that of the primate. Interestingly, the HTLV-III/LAV virus receptor is generally confined to cortical regions, a distribution consistent with the suggestion that AIDS dementia is the result of direct viral modulation.

Methods

As described by Herkenham and Pert (1982) adult squirrel monkeys, one male and one female, and male Sprague-Dawley rats (200 to 250 g) were decapitated and their brains were frozen and cut on a cryostat at 36 μm in the coronal or horizontal plane. Sections were thaw mounted on gelatin-coated microscope slides and stored under vacuum at 4°C until used.

Sections were incubated in RPMI-1640 with or without a 1:600 dilution of T4 monoclonal antibody (10 mg/ml, Ortho Diagnostics) at 0°C overnight. The following day the sections were rinsed in four 1-min washes of RPMI-1640 and crosslinked by immersion into phosphate buffered saline (PBS) plus 1 mM disuccinylsuberate (DDS) dissolved in dimethyl sulfoxide (DMSO) 45 min on ice. The sections were then rinsed in two 2-min washes of PBS, 2 min in 100 mM Tris in PBS and 3 min in RPMI-1640. Sections were then incubated in RPMI-1640 containing about 100,000 cpm ^{125}I-goat anti-mouse immunoglobulin (New England Nuclear) overnight at 0°C. Following incubation the sections were rinsed in four 1-min washes of PBS, dipped into deionized water, dried rapidly under a stream of cold air and fixed in paraformaldehyde vapors for 2 hrs at 80°C. Slides were exposed to LKB ultrofilm for 3 to 7 days after which the film was developed in Kodak D-19. Some sections were defatted in xylene and dipped into liquid emulsion (Kodak NTB-2) and exposed for 2 weeks. After exposure they were developed in D-19 and stained with thionine. Microscopic examination of these slides facilitated the identification of receptor distribution in brain microregions.

Results

T4 binding was widespread and detected in discrete areas in both monkey and rat brain forming a distinctive pattern of distribution (Figures 1 and 2). The highest density of binding occurred in the molecular layer of the dentate gyrus in both the monkey (Figure 1,D,E) and rat brain (Figure 2,B,C,D) followed by the hippocampus (Figure 1,D,E—monkey, Figure 2,B,C,D—rat). Receptors were prominent in the nuclei of the amygdala of both monkey (Figure 1,C,D) and rat (Figure 2,B) and in the superficial layers of the primate cortex especially in the cingulate (Figure 1,A,C,D,E), insular (Figure 1,A,C,D), opercular (Figure 1,A,C,D), temporal (Figure 1,C,D,E), medial temporal (Figure 1,A,C,D,E) and striate cortex (Figure 1,F). In the rat the frontal cortex (Figure 2,D), pyriform cortex (Figure 2,B) (especially near the rhinal fissure), cingulate cortex (Figure 2,D), and striate cortex had a higher density of binding than other cortical areas. A moderate density of binding occurred in the deep layers of the cortex, claustrum (Figure 1,A,C,D), caudate (Figure 1,A,C,D), putamen (Figure 1,A,C,D), hypothalamus (Figure 1,C,D), and substantia nigra (Figure 1,D) of the monkey and the accumbens, caudate/putamen (Figure 2,B), claustrum, and lateral septum of the rat. Among ancillary brain structures the choroid plexus (Figure 1,A,C,D—monkey and Figure 2,B,C—rat) and hypophysis (Figure 1,C,D) had a high density of binding.

Rat and monkey sections incubated in radiolabeled secondary antibody without prior incubation in the anti-T4 monoclonal antibody show no pattern and merely a low level of "background" optical density (Figure 1,B). Specificity is further demonstrated by our previous work in which a monoclonal antibody to the transferrin receptor revealed a different distribution pattern in rat brain using similar methods (Hill et al., 1985).

Most of the brain regions with a high density of T4 antigen are laminated cortical structures in which the prominent binding occurs in the superficial layers. This is evident in the hippocampal formation where binding is greatest in the molecular layer of the dentate gyrus and hippocampus (Figure 1,D,E—monkey; Figure 2,B,C,D—rat) and in the olfactory bulb (Figure 2,A), where binding is greatest in the external plexiform layer. In addition, in the neocortex of the monkey greatest binding is localized to superficial layers (Figure 1,A,C,D,E,F). These superficial layers are composed primarily of the dendritic and axonal branches of neurons, the cell bodies of which are in different lamina or structures. Consistent with this observation, microscopic examination of emulsion-coated slides revealed that receptor binding sites occur primarily throughout the neuropil; however, they were also observed over neurons and glial cells.

Discussion

The binding of T4 antibody to both the monkey and rat brain outlines the distinctive pattern of distribution of the T4 antigen in brain. The T4 antigen, initially known as a

marker for helper/inducer lymphocytes, now joins Thy 1.1 as an antigen first characterized in the immune system and only recently demonstrated to be present in the nervous system (Williams and Gagnon, 1982; Weber et al., 1986).

With few exceptions the T4 antigen is found in the same brain areas and with the same relative density in both monkey and rat. This, surprisingly, contradicts immunological theory which emphasizes the species-specificity of antibody reagents. However, immunological methodology such as cell sorting detects antibody binding only if very high affinity binding occurs. Our method, with its covalent cross-linking of primary antibody to antigen, can efficiently detect antibody-antigen binding with relatively low (10 nM) affinity. The similarity in distribution of the T4 antigen in the brain of two diverse mammals suggests that the pattern is stable in mammals and is therefore likely present in the same brain sites in man as in monkey and rat. Furthermore, this antigen, which appears to be conserved structurally as well as in its neuroanatomical organization, resembles in its pattern of distribution receptors for other "informational substances" which function in intercellular communication (Schmitt, 1984; Pert et al., 1985). An endogenous signal neuropeptide for the T4 antigen/receptor subserving nervous/immune system communication has not yet been described but might be expected on theoretical grounds. The presence of abundant receptors in molecular and superficial laminae, where neuronal communication occurs, supports this notion.

Since the T4 antigen acts as the receptor for the AIDS retrovirus, those brain areas with high densities of T4 antigen are targets for virus-induced behavior changes. T4 antigen is especially prominent in the cortical areas of the brain, being abundant in the hippocampus, amygdala, and many subdivisions of the neocortex. The area of highest binding, the hippocampal formation, plays an important role in learning and memory and, in addition, is a major component of the limbic system, which functions in the mediation of emotion. The amygdala, a second limbic structure, is also especially enriched with T4 antigen and is concerned with a variety of behaviors including agonistic behavior, feeding activities and sexual behavior (Kaada, 1972). Other limbic sites which have a moderate to high density of T4 antigen include the cingulate cortex, reported to be involved in maternal behaviors and vocalization (see review by MacLean, 1985); the hypothalamus, a center for the coordination of visceral functions; and the insular cortex, which functions in gustatory integration as well as being the highest way station of somatosensory integration (Friedman et al., 1986).

A moderately high concentration of T4 antigen is also found in the temporal and occipital cortices, which are involved in auditory and visual integration and in the caudate, putamen, and substantia nigra, brain areas which govern motor functions.

It should be emphasized that dense concentrations of T4 antigen are localized in all of the several cortical areas specialized for processing information from each sensory modality, i.e., olfactory, gustatory, visual, somatosensory, and auditory. Generally, it is the regions subserving "higher" cortical functions, i.e., progressively more highly processed sensory information (Turner et al., 1980), which we would predict would be most susceptible to viral modulation.

The predominantly cortical brain areas characterized by the presence of T4 antigen are thus involved in extensive and varied brain functions. The fact that these areas are the potential sites for AIDS virus infection could explain the variety of psychiatric and neuropathological abnormalities seen in AIDS patients.

Methionine Enkephalin: Enhancement of T-Cells in Patients With Kaposi's Sarcoma (AIDS)

N.P. Plotnikoff, Ph.D.,[1] J. Wybran, Ph.D.,[2] N.F. Nimeh, M.D.,[3] and G.C. Miller, Ph.D.[4]

Introduction

The enkephalins were originally described as endogenous opiate peptides modulating perception of pain (Hughes et al., 1975). Other behavioral functions for the peptides were identified including antidepressant and antianxiety actions (Plotnikoff et al., 1976).

More recently we reported that the enkephalins were immunomodulators, resulting in very significant activation of the T-cells in mice and men (Plotnikoff & Miller, 1983; Plotnikoff et al., 1983; Miller et al., 1983; Miller et al., 1984; Faith et al., 1984; Wybran, 1985). Based on the latter studies we started a series of *in vivo* studies in cancer patients.

Patient 1 (age 27) was admitted to Oral Roberts University School of Medicine with swollen lymph nodes, fever, and suspected Kaposi's sarcoma and pneumocystitis. Initially he was placed on Pentamidine therapy for suspected Pneumocystis carinii pneumonia. After the initial treatments with Pentamidine, the patient was placed on methionine enkephalin treatment. The schedule employed was daily infusion the first week for 5 days and twice a week thereafter. The dose employed was 10 μg/kg prepared in a normal saline solution and infused over a 30-minute time course. Twenty-four hours after infusion, blood samples were withdrawn and analyzed for T-cells (E rosettes), OKT 3 T lymphocytes, mature thymocytes, OKT 11 T lymphocytes-early development stage thymocytes, T helper cells (OKT 4), T suppressor cells (OKT 8), blastogenesis or mitogen stimulated proliferation, phytohemagglutinin (T helper cell mitogen), concanavalin A (a T helper and T suppressor cell mitogen), pokeweed (a T dependent B cell mitogen), and Staph A (a B cell mitogen). NK cell assay (natural killer cells) was conducted against the K-562 tumor cell line labeled with ^{51}Cr (7).

This patient received infusions of methionine enkephalin (10 micrograms per kilogram) each day of the first week (5 days, Monday through Friday). Blood samples were taken each day before infusion of methionine enkephalin. The data in Table 1 indicate that absolute number of T helper cells increased (57 to 94/mm^3) and the absolute number of suppressor cells (OKT 8) decreased from 382 to 264 per mm^3 on the fifth day. There was a slight increase in OKT 3 and OKT 11 cells. The T helper/T suppressor ratio rose from 0.149 to 0.354. The total lymphocyte count dropped from 516 on day one to 368 on day four and rose again to 550 on day five. Active T-cells rose significantly from 201 on day one to 396/mm^3 on day five.

No methionine enkephalin was infused on day six or day seven. On day eight blood samples were withdrawn followed by methionine enkephalin infusion (dose of 25 μg/kg) corresponding to one-half of the first week total dose. The T-cells were still elevated on day eight compared to day five. T helper cells were 119 compared to 94; T suppressor cells increased to 409 from 264; OKT 3 increased from 341 to 491/mm^3; and OKT 11 increased from 429 on day five to 558 on day eight. The active T-cells increased to 565/mm^3 on day eight compared to 396/mm^3 on day five. Furthermore, the total lymphocytes increased to 774/mm^3 on day eight compared to 550/mm^3 on day five. The NK cell assay on day eight was slightly decreased compared to day one values. Finally, there was a significant increase in interleukin 2 receptors.

On day 11 blood samples were taken once again followed by methionine enkephalin infusion. All of the T-cell subsets increased except active T-cells. The total lymphocyte count diminished slightly.

The patient was discharged from the hospital with signs of subjective improvement. Of great interest was that the original lesion of the sarcoma, including biopsy hole, was crusting and healing. Lymph nodes in the axillary and groin area were palpably smaller.

AIDS Patient Study*

Methionine enkephalin was given to Patient 2 (a 26-year-old male Caucasian AIDS patient from Zaire, Africa) whose clinical manifestations included resected cerebral lymphoma and opportunistic infections (Candida albicans and Mycobacteriumbovis). Methionine enkephalin (UCB, Brussels) was administered at a dose of 20 μg/kg in saline perfusion over a period of 30 minutes. Lymphocyte populations were studied using monoclonal antibodies (Ortho, Raritan, NJ, and Becton-Dickinson, Mtn. View, CA). After incubation with the monoclonal antibodies, the cells were further incubated with goat antimouse coupled particles of colloidal gold (Janssen Life Science Products, Beerse, Belgium) and the smears were put in a silver developer and counter-stained with May-Grunwald-Giemsa (Romasco et al., in press). This smear method allows morphology and is about 20 times more sensitive than immunofluorescence.

---

*By Dr. J. Wybran (Brussels, Belgium).

Results

Lymphocytes	Before (%)	After 2 h (%)	After 24 h (%)
OKT 3	30	26	27
OKT 10	45	53	49
OKT 11	31	34	31

Blood T-cells increased in number slightly as judged by the OKT 10 and OKT 11 antisera. Of special interest is the increase in OKT 10 which is similar to *in vitro* data obtained by incubating human lymphocytes with methionine enkephalin (Seligmann et al., 1984).

Discussion

The patient with Kaposi's sarcoma was diagnosed as an AIDS patient on the basis of defective T helper cell levels compared to T suppressor cell levels. Seligmann et al. have indicated that AIDS is characterized by a decreased OKT 4 lymphocyte subset (Seligmann et al., 1984).

The present study with methionine enkephalin is based on our earlier findings that methionine enkephalin stimulates PHA-induced blastogenesis (a T helper cell antigen) in mice and also markedly stimulated OKT 4 (T helper cell) production in normal volunteers (Plotnikoff & Miller, 1983; Plotnikoff et al., 1983). Similar elevation of T helper cells by methionine enkephalin was seen in the present AIDS patient with Kaposi's sarcoma. In addition there is a marked elevation of interleukin-2 receptors to 48 percent of the lymphocytes compared to 14 percent on day one. Recently Wybran reported that methionine enkephalin stimulated production of interleukin-2. In addition, the primary sarcoma lesion appears to be healing. Similar findings on T-cell subsets were seen in the AIDS patient studied by J. Wybran.

Molecular Biology: Relevance to Neuropsychopharmacology and Psychiatry

Chair:

Samuel H.Barondes, M.D.

University of California at San Diego
La Jolla, CA 92093

Introduction

It is now established that brain function depends, in large part, on the synthesis, processing, and degradation of many of its constituent proteins. There is also evidence that modification of a single brain protein can have dramatic structural and functional consequences. These general conclusions came from studies using classical molecular and genetic techniques.

Like the rest of biology, studies of brain function are being greatly facilitated by recent advances in molecular biology. These have, for example, dramatically increased our ability to detect new proteins that are critical for brain function. They also provide the opportunity to identify directly the genetic basis for psychiatric disorders. The contributions to this symposium describe exciting applications of molecular biology to neuropsychopharmacology and psychiatry.

Bloom's paper shows how recombinant DNA technology is being applied to identify messenger ribonucleic (RNA) molecules that are specific to brain, some of which code for precursers of neuropeptide transmitters. Beginning with a library of DNAs complementary to brain messenger RNAs, clones representing brain-specific messenger RNAs were isolated. This was achieved by first showing that these clones hybridized with messenger RNA from brain but not other tissues. In this way it was estimated that there are about 30,000 messenger RNAs unique to brain, and several have been studied in great detail. The major focus of Bloom's contribution is on the discovery of brain messenger RNAs that code for specific neuropeptides; and the subsequent use of other techniques to localize them and evaluate their function.

Herbert and colleagues describe the application of another general strategy to study a critical element in nervous system function. They have concentrated on factors that regulate expression of the genes that direct the synthesis of specific neuropeptides. They are also concerned with regulation of the processing of the protein precursors of these peptides by various cellular mechanisms. The focus of their contribution is on gene transfer techniques which have revolutionized the study of these regulatory processes. They describe how genes coding for protein precursors of neuropeptides can be introduced into a variety of cells. The techniques they use permit either stable integration of the transferred genes into the nuclear chromatin or their temporary expression in the cytoplasm of recipient cells. The transferred genes and their products are ideal subjects for studies of regulation of gene expression and of processing of gene products. This approach promises to markedly increase our understanding of regulation of brain protein and peptide metabolism.

What is particularly exciting about the introduction of recombinant DNA techniques into our specialized fields of interest is that it should greatly accelerate our detailed understanding of brain function and psychiatric disorders. Traditional psychiatric research has moved fairly slowly because each experiment is difficult to do and because the assays involved frequently take long periods of time. In contrast, the technologies described here promise rapid advances in knowledge, even in areas as complex as those of concern to this audience.

Identifying Neuropeptides by Gene Cloning

Floyd E. Bloom, M.D.[1]

A variety of specific molecules have provided insight into the limited knowledge of cellular operations in the brain. Neurotransmitter molecules, and the distinct molecular systems by which they are synthesized, stored, released, and recognized by their target cells, perhaps come most easily to mind. However, the catalog of neurotransmitters is far from completely compiled, and many important genetic and non-genetic disorders of the nervous system may only be amenable to diagnosis, treatment, and ultimate prevention when new transmitters are added to the list as probes of the pathology. Expanding the list of transmitter-related molecules thus can be taken to be as important to clinical problems of the brain as they will be to enlarging our understanding of the fundamental processes by which the brain performs its complex tasks. Our approach has been to attack the molecular specificity of the mature rat brain with a direct examination of the complexity of the genetic messages being expressed there. Every protein product being expressed in brain, as in all cells, depends for its synthesis on the transcription of a specific piece of genetic information into a messenger RNA that guides synthesis of the gene product. Using the powerful tools of recombinant DNA technology, my colleagues and I have embarked on a long-term study aimed at characterizing the messenger RNA molecules that are specific to brain. To do so, we have prepared an initial library of brain mRNA by recombinant cloning. Clones showing evidence of successful insertion of genetic information have been screened with RNA hybridization, so-called Northern blotting, and inserts representing brain specific mRNAs have been isolated. Those cloned brain mRNAs were then sequenced and the amino acid sequences of the products for which they code were deduced. Selected zones of these deduced peptides were then synthesized and used to develop peptide selective antisera. The antisera in turn were used to screen brain sections and protein extracts in order to document that novel molecules deduced from the structure of the mRNA being expressed selectively in brain were actually made and expressed in brain. Our results suggest that, on average, the mammalian brain derives its complexity through only 30,000 or so messenger RNAs specific to the brain, in that they are not detectible in other major organ systems. Among the more interesting of these highly specific, chemically determined marker molecules, we have found both neuron-specific and glia-specific examples. Our most intensively studied system has satisfied some, but not yet all, of the cellular, subcellular, and biochemical criteria of a neurotransmitter peptide pro-hormone. Thus, a genetic analysis of brain complexity and functional specificity is a potent and efficient strategy for molecular discovery.

Introduction

The topic of neuropeptide identification represents one of the most active aspects of cellular and molecular neuroscience with relevance to American College of Neuropsychopharmacology interests. In this short overview, I cover the major thrusts of such efforts. Molecular discovery in the neurosciences has, until recently, largely focused on neurotransmitters and hypothalamic hypophysiotrophic hormones. Historically we can view the topic of transmitter discovery as having had a "classical" period and a "modern" period. The "classical" period began with the discoveries of Dale, Loewi, Elliott, and their contemporaries when chemical signals were few, cellular arrays were confusing, and chemical isolation methods were primitive. Currently, we are in transition to an era

---

[1] Division of Preclinical Neuroscience and Endocrinology, Scripps Clinic and Research Foundation, La Jolla, CA 92037.

in which powerful molecular biological methods maintain a continued pace of discovery even after all the "easy" transmitter discoveries were already made.

Strategies of Transmitter Discovery

As we look back upon the growing list of consensus transmitters (*see* Bloom, 1984a,b) those discovered in the classical period can attribute their discovery to one of two strategies, depending on whether the factor was discovered before or after the biological actions for which it is now recognized.

In the "Factor First—Function Later" strategy are substances that bear mainly chemical names: acetylcholine, gamma amino butyrate, dopamine, glutamate, aspartate, glycine, or taurine. They earned chemical names because it was their chemical structure for which they were exclusively identified as biological products, without functional inferences. No peptides, until recently, were among this set.

In the "Assay First—Factor Later" strategy, the development of a bioassay for an unknown regulatory factor became the starting point for a purification-isolation process. This was the classical approach of Starling and the early gastrointestinal regulatory peptides, for insulin and glucagon, as well as "sympathin" of Cannon and colleagues. All of the largely peptidic messengers resulting from this approach carry functional names rather than chemical names: gastrin, cholecystokinin, prostaglandin, Substance P, angiotensin, oxytocin, vasopressin, as well as more conventional small molecules like the biogenic amines, adrenalin, histamine, and serotonin.

This methodology reached its zenith under the skilled prodding of Guillemin, Schally, McCann, and others who pushed their colleagues to detect the hypophysiotrophic factors conceived by Geoffery Harris in the mid-1940's and early 1950's (Guillemin, 1978; Krieger, 1983), requiring the development of sensitive new methods for peptide isolation, purification, and sequence analysis, as well as very large amounts of freshly dissected cattle brains. From this effort came the "Assay-First," functional names for thyrotropin releasing hormone, somatostatin, gonadotropin-releasing hormone, and prolactin, and including the last two of the originally postulated hypophysiotrophic factors predicted, corticotropin-releasing factor (Vale et al., 1981) and growth hormone-releasing factor (Guillemin et al., 1982) have been solved. This neo-classical approach is still being widely applied, as evidenced by the endorphins saga (*see* Snyder, 1984) and new families of gut and brain peptides.

Two Modern Strategies of Transmitter Discovery

Two series of developments over the past half decade have made their impressive effects on the emerging list of transmitters recognized. Both derive from the recognition of common chemical principles, but use different ways to exploit the general feature. Mutt and colleagues (Tatemoto & Mutt, 1980, 1981) looked at the frequent occurrence of C-terminally amidated peptides that functioned as messengers. Using chemical methods that detect C-terminally amidated peptide fragments, they were able to identify other important molecules with this common structure. Using this approach, they found new peptide members of the Glucagon-VIP family and the pancreatic polypeptide family, using the biochemical test as the primary assay for their isolation and classical structural determination.

The second new approach is based on the central dogma of molecular biology—all peptides are synthesized under the direction of a specific messenger RNA (mRNA) encoded by the gene for that peptide. With the emergence of recombinant DNA technologies, restriction endonucleases, and nucleotide sequencing, a new opportunity for molecular discovery became available. Nakanishi et al. (1979) were the first to use molecular biological methods to determine the sequence of the pituitary mRNA that encodes the expression of the common precursor of corticotropin and β-endorphin. Starting with the mRNA purified from 40 bovine pituitaries, they were able to analyze a cDNA library and identify this specific mRNA, determine its nucleotide sequence, and deduce the amino acid sequence of the gene product. In addition to revealing the continuous encoding of corticotropin and β-lipotropin, this mRNA sequence deduction also revealed a third biologically relevant peptide, termed gamma-melanocyte stimulating hormone (MSH) based solely from the mRNA sequence on the basis of its structural analogy to alpha and beta MSH.

Subsequently, the recombinant DNA approach has been employed to obtain the prohormone structural sequences, and some of the genomic sequences for almost every one of the previously identified neuropeptides: all of the major branches of the endorphin family (Gubler et al., 1982; Kakidani et al., 1982; Nakanishi et al., 1979; Noda et al., 1982); somatostatin (Goodman et al., 1982; Montminy et al., 1984); VIP (Itoh et al., 1983); neuropeptide tyrosine (Minth et al., 1984); oxytocin and vasopressin (Schmale & Richter, 1984; Ivell & Richter, 1984); gastrin (McDonald et al., 1983); corticotropin releasing factor (Furutani et al., 1983); growth hormone releasing factor (Gubler et al., 1983; Mayo et al., 1983); Substance P (Nawa et al., 1983); cholecystokinin (Deschenes et al., 1984; Gubler et al., 1984); luteinizing hormone/releasing hormone (Seeburg & Adelman, 1984): and the amphibian skin pro-thyrotrophin releasing hormone (Richter et al., 1984). Most recently, a neuropeptide with the properties of an endogenous benzodiazepine antagonist (Alho et al., 1985) and the previously uncertain prolactin-inhibitory factor peptide (Nikolics et al., 1985; Phillips et al., 1985) have been identified by similar methodology and their neuronal locations determined immediately.

Potentially new, previously unsuspected coexpressed peptides were suggested strictly from mRNA sequences to predict a new form of VIP (Itoh et al., 1983) and Substance P (Nawa et al., 1983). Moreover, pursuit of the pro-hormone for calcitonin led Rosenfeld and Evans and their collaborators to the recognition that rearrangements of parts of the mRNA domains of the pro-calcitonin could give rise to a "calcitonin-gene related peptide" (Rosenfeld et al., 1983) which in fact was found in special segments of the rat CNS and had unsuspected biological activity. In fact, the recombinant approach has yielded so many new molecules, all roughly equivalent candidates for consideration as neurotransmitters, that the next major phases of the investigation, localization and assessment of function, have lagged far behind.

Another Possible General Strategy for Transmitter Discovery

The appearance of the report suggesting that "pro-opiocortin" was actually "pro-opiomelanocortin" gave rise to the idea that better analysis of brain mRNAs could reveal unexpected multiple, biologically important, cleavage products. Believing that such an approach might not only yield neurotransmitters but might also yield information important to the complete characterization of the properties of neurons and their cell assemblies, my colleagues and I began an effort to employ recombinant DNA methods as a broad open-ended approach to characterizing important but unpredicted agonists and response systems of the brain. The continuous stream of results (Bloom et al., 1985; Milner & Sutcliffe, 1983; Milner et al., 1984; Malfroy et al., 1985; Sutcliffe et al., 1983a,b, 1984) suggest that all of our opportunistic wishes may be realizable.

Molecular Biologic Approaches to Identification

We have used molecular cloning methods to purify randomly chosen copies (cDNAs) of rat brain messengers RNAs (mRNAs). Poly(A)$^+$ RNA was purified from the brains of adult rats, copied into double stranded cDNA, and inserted into the plasmid pBR322 for cloning in *E. coli.* Clones bearing cDNA inserts that were at least 500 base pairs in length were nick translated and evaluated for their patterns of hybridization to mRNAs isolated from brain, liver, and kidney. Those clones that hybridize to brain mRNAs, but not to mRNAs extracted from other organs, we define as being brain-specific.

This categorization has been extremely productive since such basic quantitative characterizations had not previously been available. For example, Milner and Sutcliffe (1983) determined the approximate sizes of the mRNAs in brain, their relative abundances, and the total complexity of the brain mRNA population. Since the average length of brain-expressed mRNAs could thus be specified (approximately 4,000–5,000 nucleotides), and since the overall length of mammalian mRNA complexity has also been estimated (at 1.4 × 10^8 nucleotides in length), it is possible to calculate that approximately 30,000 mRNAs are expressed in the brain. The brain-specific mRNAs tend to be larger and more rare than the mRNAs found in other major organ systems, suggesting that genetic messages in brain may encode for more complex translation products. By using the method of "Northern Blot Analysis," one can separate the mRNAs transcribed in a given organ, like brain, liver, or kidney, and use the radioactive cDNA probes of brain-derived mRNAs to determine their presence or absence in other organs. Using such methods, mRNAs expressed in brain, but not detectable in liver or kidney, are operationally defined as "brain-specific" (Milner & Sutcliffe, 1983) and constitute over half of those expressed in brain.

Mapping the Brain With Molecular Biologically Defined Markers

Attempts to define the specific properties of the nervous system have generally begun with comparative analysis of its chemical or functional differences with cells of other organ systems. Likewise, attempts to clarify the uniquely complex structural organization of the brain were first approached through empirically derived cell staining methods supplemented later by more powerful and specific circuit tracing methodologies. During the past decade, anatomic studies have been powerfully extended by immunocytochemical probes specific for products known or inferred to be produced by neurons or glia. However, most neurotransmitter substances and their related synthetic or catabolic enzymes and receptors are not exclusive to the nervous system, being detected also in endocrine and exocrine tissues. Thus, relatively few brain-specific or neuron-specific molecules have been detected as yet.

An alternative approach to the specific, but unknown, properties of neurons, both generally and individually, is the direct analysis of the gene products expressed in brain, as noted above. Our examination of one apparently "brain-specific" protein product, as defined by our criteria, seems especially relevant to complete our documentation of the powers of neuropeptide localization. The clone 1B236 corresponds to a brain-specific mRNA of approximately 2,500 nucleotides, from which we have sequenced and deduced the amino acid order of a protein some 318 amino acids in length which was never previously identified. In RNA or "Northern" blotting analyses, 1B236 mRNA is found to be unequally distributed in the adult rat brain, with an abundance roughly following a caudal-to-rostral gradient in macroregional dissections (Sutcliffe et al., 1983a,b). Antisera raised against three fragments of the deduced amino acid sequence (Peptides 5,6,7 or P5, P6, P7; Figure 1), provided preliminary evidence of cellular heterogeneity of this presumptive gene product in pontine, cerebellar, cortical, and limbic structures (Sutcliffe et al., 1983).

An extensive, but virtually identical, pattern of immunoreactive fibers was visualized throughout the normal rat CNS with antisera raised against P5, P6, or P7. The immunoreactivity was especially dense in olfactory bulb and several other specific nuclei and defined regions (*see* Bloom et al., 1985). Virtually identical patterns of immunoreactivity were demonstrated by antisera against either of three synthetic peptides corresponding to non-overlapping regions of the carboxy-terminal of the presumptive polypeptide. These superimposable maps provide strong support for the interpretation that this protein corresponding to an mRNA cloned and selected as brain-specific (Sutcliffe et al., 1983a,b) is expressed in brain, and that this gene product is shared by a number of neuronal systems.

Given this array of features, as well as the evidence from mRNA hybridization studies already reported that attribute the 1B236 mRNA to neuronal and not glial sources (Sutcliffe et al., 1983a,b), we conclude that 1B236 protein is expressed by a selective set of central neurons. The peptides P5, P6, and P7 were initially selected as immunogens because these sequences were flanked in the primary 1B236 sequence by basic dipeptides that we considered to be possible proteolytic cleavage sites. Ongoing studies aimed at defining the molecular forms of the 1B236 peptide (Malfroy et al., 1985) indicate that small

FIGURE 1. Structure of the 1B236 protein. (A) The 1B236 mRNA, the p1B236 cDNA clone, and the 1B236 protein are schematically represented (2). The mRNA is ≈2,500 nucleotides in length: the cDNA clone p1B236 corresponds to the 3′ 1,500 nucleotides. The open reading frame in the cDNA sequence is shown by the filled bar; the 3′ noncoding region is shown by the open bar. Also indicated are the positions of peptides P5, P6, and P7. (B) The carboxyl-terminal sequence of the 1B236 protein is shown with peptides P5, P6, and P7 underlines. Notice the pairs of basic amino acids flanking the underlined peptides (*see* Malfroy et al., 1985).

peptides, similar in size to those selected for use as immunogens, and sharing immunoreactivity with them, may be formed by posttranslational processing. Such evidence will be critical to validate the hypothesis (Sutcliffe et al., 1983a,b) that the 1B236 protein is the precursor for a series of possible smaller messenger peptides. Until such issues can be firmly established, the observed ability of P5 and P6 to influence spontaneous or elicited activity of hippocampal or neocortical neurons (S.J. Henriksen, personal communication) and spontaneous locomotor behavior (G. Koob, personal communication) lack any direct transmitter-like connotation. However, the generally superimposable cellular maps, the vesicular location, the predominance of P6 immunoreactivity in those neurons which do become visualizable after colchicine pretreatment, and the loss of terminal like staining for all three peptides when cell body immunoreactivity is enhanced are consistent with the view that there is a large precursor form of the protein, which is processed during its transit through the perikaryal cytoplasm en route to nerve terminals.

Interpretations

Every new neuronal marker, including those that are likely to act as intercellular signals or signal transducers, has relevance for the College because it not only helps us sort out the structural and functional puzzles of the normal human brain, but it also provides specific markers to be used in diagnostic tests. The advent of molecular biological methods, especially that aspect of molecular biology that has been dubbed "cloning" has greatly accelerated the pace and breadth of molecular hunting expeditions. The avenues which my colleagues and I have embarked upon have already yielded more than a half dozen profoundly insightful molecular markers that are, in preliminary evidence, easily detected in human brains. The evidence seems clear therefore that knowledge such as this will remain of importance for generations to come.

Use of Gene Transfer Techniques to Study Neuropeptide Gene Regulation

Edward Herbert, Ph.D.,[1] Audrey F. Seasholtz, Ph.D.,[1] and Michael Comb, Ph.D.[2]

Introduction

Studies of vertebrate and invertebrate nervous systems over the past 20 years have suggested that simple forms of behavior and modifications of behavior attained through learning are expressed by changes in neurotransmitter levels at synapses and by changes in post-synaptic neurons that govern responses to neurotransmitters. In this model, an increase in neurotransmitter release may lead to learning by strengthening a synaptic connection of a complex neuronal circuit mediating that learning behavior. Persistence of the change in neurotransmitter release will create memory of the learning experience. Changes due to learning are imprinted on post-synaptic elements possibly through alterations of receptors and transmitted to other neurons or effector organs to produce a behavioral response.

What mechanisms underlie these changes at the synapse? Are specific genes turned on or off or activated to produce these changes in neurotransmitter levels or receptor levels? In the past 10 years, advances in molecular genetics and biochemistry have provided the tools necessary to answer these questions. These tools make it possible to clone genes that code for neuropeptides, neuropeptide receptors, and neuropeptide processing enzymes and to determine how their expression is regulated by intracellular and extracellular control factors.

Neuropeptides

A milestone in the field of neuroscience has been the discovery of a vast repertoire of neuropeptides that mediate specific behavior patterns in animals. Upon release at the synapse, neuropeptides like other kinds of neurotransmitters combine with receptors on post-synaptic neurons or target cells to initiate an intracellular cascade that leads to an electrical or chemical response. All of these processes (neuropeptide production and release, receptor function and intracellular cascades) must be defined at the molecular level to achieve an understanding of behavior. Molecular biology has provided us with methods and tools necessary to define these processes.

The impact of molecular biology on neuroscience is no more apparent than in the study of opioid peptides. Since the discovery of Met- and Leu-enkephalin in 1975 by Hughes et al., a large family of peptides exhibiting opioid activity have been isolated and subsequently shown by recombinant DNA techniques to be derived from three different precursor proteins (Figure 1). Proopiomelanocortin (POMC) gives rise to β-endorphin, ACTH, and melanocyte stimulating hormones (MSH) (Mains et al., 1977; Roberts and Herbert, 1977; Nakanishi et al., 1979). Proenkephalin (proenkephalin A) contains six Met-enkephalin sequences and one Leu-enkephalin sequence and gives rise to Met- and Leu-enkephalin as well as a variety of larger enkephalin containing peptides (Noda et al., 1982; Gubler et al., 1982; Comb et al., 1982; Legon et al., 1982). Prodynorphin (proenkephalin B) contains three Leu-enkephalin sequences and gives rise to α- and β-neoendorphin and dynorphin A and dynorphin B related peptides (Kakidani et al., 1982). Each opioid precursor undergoes proteolytic processing to generate biologically active peptides during its maturation and transport through the secretory pathway to storage vesicles (Douglass et al., 1984; Udenfriend and Kilpatrick, 1983). Recent evidence suggests that all three opioid precursors can be cleaved to different sets of biologically ac-

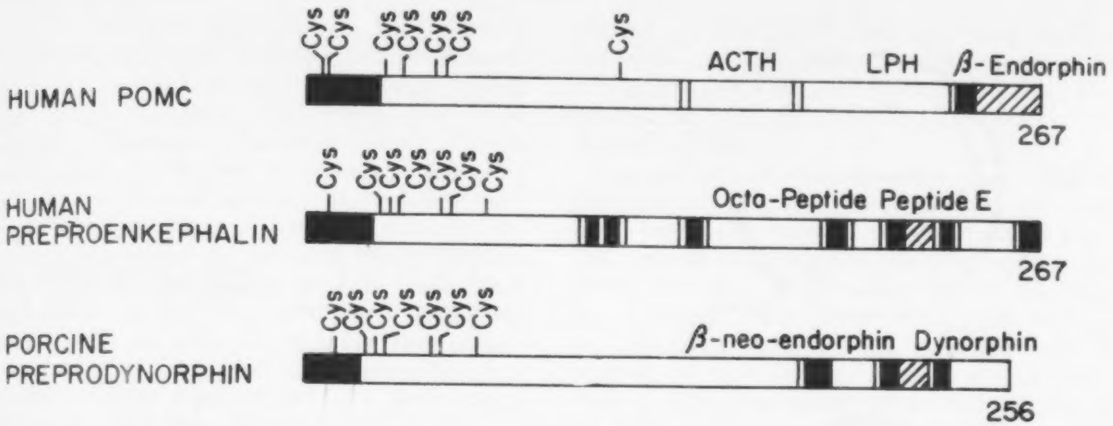

FIGURE 1. Structure of the three opioid peptide precursors; proopiomelanocortin (POMC), preproenkephalin and preprodynorphin. The black box at the left end of the precursors represents the signal sequence. The smaller black boxes are enkephalin sequences (Met- or Leu-enkephalin) and the double lines flanking the bioactive peptide domains represent pairs of basic amino acid residues.

tive peptides in the different tissues in which they are expressed (Douglass et al., 1984; Udenfriend and Kilpatrick, 1983; Seizinger et al., 1984). For example, POMC is cleaved in the anterior lobe of the pituitary to produce ACTH, β-LPH, and an N-terminal fragment while in the intermediate lobe of the pituitary this same molecule is processed to β-endorphin, α-melanocyte stimulating hormone (MSH), and a C-terminal fragment of ACTH which have different biological activities and target tissues (Herbert, 1981) (Figure 2). Similarly, proenkephalin is cleaved to free enkephalins in several brain regions while processing in the adrenal medulla yields a variety of large enkephalin containing peptides and very little free enkephalin (Udenfriend and Kilpatrick, 1983; Seizinger et al., 1984; Herbert, 1981; Liston et al., 1983).

Regulation of synthesis and release of peptides derived from opioid precursors is also tissue specific. Synthesis and release of POMC peptides, for example, are stimulated by corticotropin releasing factor (CRF) and vasopressin and inhibited by glucocorticoids (Vale et al., 1981; Rivier et al., 1982; Axelrod and Reisine, 1984) in the anterior lobe of the pituitary, whereas in the intermediate lobe, synthesis and secretion of POMC peptides are not affected by these agents but rather by input from dopaminergic neurons with cell bodies originating in the hypothalamus (Rosa et al., 1980).

The release and synthesis of proenkephalin are also differentially regulated in a variety of tissues. Chronic administration of haloperidol causes a twofold increase in Met-enkephalin immunoreactivity in rat striatum and globus pallidus, but not in hypothalamus, septum, or medulla oblongata where it is also expressed (Tang et al., 1983). In bovine adrenal medulla, neural input regulates the release of enkephalin-containing peptides (Lewis et al., 1981). In cultures of chromaffin cells from bovine adrenal medulla, the levels of enkephalin peptides and proenkephalin mRNA are dramatically increased by treatment with cAMP analogs (Quach et al., 1984) or activators of adenylate cyclase (Eiden et al., 1984). At present we know very little about the mechanisms involved in the action of these agents. Do these compounds cause an activation or repression of the opioid genes? What are the molecular mechanisms involved in these types of regulation of gene expression?

Gene Transfer Approaches to the Study of Neuropeptide Gene Expression

The availability of cloned genes and the development of new methods which permit their efficient transfer into eukaryotic cells have revolutionized the field of gene regulation and provided the means of examining the questions raised above. A variety of gene

transfer techniques are now available which allow us to study the regulation of expression at a variety of levels. Transcriptional regulation appears to be controlled by a variety of DNA sequences in the structural gene (*cis*-acting elements) and *trans*-acting regulatory elements (factors that interact with *cis*-elements). The DNA sequences involved in *cis*-acting transcriptional regulation are quite diverse in function and structure, and act in the general stimulation of transcription (promoters and enhancers), tissue-specific gene expression, or the induction (or repression) of transcription by the action of specific agents. The *trans*-acting regulatory elements are often specific protein factors which interact with the *cis*-acting DNA sequences. Methylation patterns may also play a role in controlling the transcriptional activity of a gene. Gene transfer techniques can also be used to examine the sequences in the gene or cDNA which provide signals for post-translational modification, processing, and secretion. Therefore, by constructing specifically mutated genes and analyzing their activity in a variety of expression systems, it is now possible to determine the role of specific DNA sequences in different aspects of gene expression.

Gene transfer experiments with cloned genes can be divided into two major categories: a) stable transfections, and b) transient assay systems. To study stably transfected cell lines, one isolates a clone of eucaryotic cells that has integrated the foreign gene into its chromosomal DNA. The major advantage of this system is the ability to isolate stable cell lines which can be grown indefinitely in culture and used to study a variety of regulatory phenomena. The gene of interest can be introduced into the eucaryotic cells by several different methods: a) chemical methods such as the calcium phosphate precipitation method or the DEAE-dextran method; b) physical methods such as microinjection or electroporation; c) viral-mediated DNA transfer; and d) fusion of DNA-containing membranous vesicles such as liposomes, envelopes of Sendai virus particles, or protoplasts to cells.

The calcium phosphate precipitation method is the most widely used procedure, but is somewhat limited at the present time in the range of target cells which give high transfer efficiency. Microinjection and fusion techniques can be used to introduce the gene of interest into almost any mammalian cell, and microinjection of fertilized mouse embryos has allowed the performance of regulation studies in transgenic animals. Both RNA and DNA viruses have also been used very successfully as gene transfer vectors. However, all of the long term assay systems (regardless of the method used for gene transfer) suffer one limitation: an inability to control or evaluate the region of the genome into which the introduced gene is integrated. Thus, different clones carrying the same gene may show significant variability in RNA and protein production depending upon differences in location of the foreign gene in the host.

The second gene transfer approach involves the use of transient expression systems. In these systems, the foreign gene or cDNA is introduced into eucaryotic cells and its expression is assayed within a few hours to days prior to integration into the genome. The advantages of these assays are simplicity and rapidity. Furthermore, because the transferred molecules remain episomal (extrachromosomal), the problems associated with random chromosomal integration can be avoided. The major disadvantages are the relatively low levels of expression and the inability to conduct experiments over more than a few days. A variety of transient systems are presently available. In the first system the control region of the gene of interest is fused to the coding sequence of a gene which is readily assayed by enzymatic means such as *E. coli* chloramphenicol acetyltransferase or herpes thymidine kinase. With this type of system one can assay the transcriptional activity of the foreign gene by a simple and rapid enzymatic assay. A second transient assay utilizes the *Xenopus* oocyte. *Xenopus* oocytes will efficiently transcribe and translate an injected gene and can therefore be used to study transcriptional regulation and post-translational processing. The third transient assay system involves the use of vaccinia virus as a gene transfer vector. Vaccinia is a cytoplasmic virus with a broad host range and is therefore best-suited for examining the role of specific DNA sequences in controlling the processing and secretion of a protein in different cell lines.

We are currently using these gene transfer techniques to study the regulation and expression of the human proenkephalin gene and several other opioid genes. A mouse anterior pituitary corticotrophic cell line has been stably transfected with the human proenkephalin gene and the characteristics of several of the isolated clones will be discussed. The expression of proenkephalin in two transient systems will also be discussed: a) proenkephalin fusion genes, and b) vaccinia virus. By studying the expression and regulation of the wild-type human proenkephalin gene and a variety of site-specific mutants in both the stably transfected cell lines and a variety of transient expression systems, we hope to gain a better understanding of the DNA sequences involved in the expression and control of this gene.

Stably Transfected Cell Lines

The human proenkephalin gene has been introduced and expressed in AtT-20 cells in order to study the transcriptional regulation of this gene and to elucidate the mechanisms underlying processing of proenkephalin (Comb et al., 1985). The AtT-20 cell line was selected as the host system for these studies because the cells do not express proenkephalin, but possess well developed secretory vesicles and store and release large amounts of ACTH and β-LPH. They also respond to physiological regulators and process POMC in a manner similar to that of anterior pituitary cells. Hence these cells provide a well characterized secretory pathway in which to examine the processing and chemical modifications of neuropeptide precursors.

A recombinant plasmid containing the human proenkephalin gene ligated to pBR322 was introduced into AtT-20 cells by cotransformation with pRSVneo, a plasmid containing the *neo* gene which confers resistance to the aminoglycoside drug G418 and therefore acts as a dominant selectable marker as shown in Figure 2. Stable transformants which had one or more copies of the human proenkephalin gene integrated into the mouse chromosomal DNA expressed a 1.45 kb mRNA identical in size to authentic human proenkephalin mRNA.

Analysis of protein extracts from AtT-20 transformants using a radioimmunoassay specific for Met-enkephalin demonstrated that these cells synthesize proenkephalin protein and cleave it to form free Met-enkephalin. This result suggests that the processing enzymes present in AtT-20 cells can also recognize and efficiently process the cleavage sites flanking the Met-enkephalin sequences in the proenkephalin precursor. The secretion of Met-enkephalin from these cells was also examined. Treatment of cells with corticotropin releasing factor (CRF) resulted in a twofold stimulation of secretion of both ACTH and Met-enkephalin immunoreactivity. Therefore, these stably transformed cell lines will be very useful for studying the molecular mechanisms involved in processing and secretion of the proenkephalin protein along with the transcriptional regulation of the gene.

Transient Expression Systems

Fusion Genes: In these studies the putative regulatory region of a gene is linked to an enzymatic reporter function which is readily assayed in eucaryotic cells. The amount of enzyme activity reflects the amount of protein produced under the control of the linked regulatory region and thus provides a direct indication of the level of gene expression. We have selected the *E. coli* chloramphenicol acetyltransferase (CAT) reporter function developed by Gorman et al. (1982) because a) CAT activity is easily and sensitively assayed; and b) there is no interfering endogenous activity since CAT activity is not present in mammalian or avian cells. By fusing the 5′ end of the human proenkephalin gene to the CAT gene, we can analyze the efficiency of the proenkephalin gene promoter, map transcriptional control elements, and test for elements of the gene required for cell-specific expression following transfection into mammalian cells.

The fusion gene contains the first 406 base pairs (bp) of the human proenkephalin gene (193 bp of 5′ flanking region and 213 bp of human proenkephalin DNA including exon I, intron A, and exon II) fused to the CAT gene. The 3′ untranslated sequences, poly A addition sites and 3′ flanking sequences of the human proenkephalin gene were also placed 3′ to the CAT gene. In this fusion gene plasmid (called ENKAT-12), CAT expression is driven by the linked human proenkephalin promoter and utilizes both 5′ and 3′ human proenkephalin control signals (such as the transcription termination signal; Figure 3). This fusion plasmid was transfected into eukaryotic cells for transient expression by the calcium phosphate precipitation method. The cells were harvested at 36 to 48 hours post-transfection, and cell extracts were then assayed for CAT activity using ^{14}C-chloramphenicol and acetyl CoA. The production of chloramphenicol acetate was assayed by thin layer chromatography.

The transient expression of ENKAT-12 was examined in a variety of cell lines: rat adrenal PC-12 cells, mouse pituitary AtT-20 cells, human HeLa cells, mouse L cells, and monkey CV-1 cells. Relatively high levels of CAT expression were demonstrated 36 to 48 hours after transfection in all the tested cell lines, with values ranging from 20 to 80 percent of the level of expression directed by RSVcat, a plasmid containing the strong rous sarcoma virus promoter in front of the CAT gene. Thus, the 5′ 406 bp of the human proenkephalin gene contains an efficient promoter region capable of directing high levels of CAT expression.

The ENKAT-12 plasmid was also used in these transient assays to identify potential regulators of the human proenkephalin gene. Several groups have reported that proenkephalin mRNA levels are regulated by cAMP analogs (Quach et al., 1984) or activators of adenylate cyclase (Eiden et al., 1984). cAMP is thought to act as a second messenger system in transcriptional regulation of eucaryotic genes. Activation of adenylate cyclase by a variety of different mechanisms causes increased levels of intracellular cAMP. Increased cAMP concentrations cause increased cAMP dependent protein kinase activity, and changes in protein phosphorylation may be responsible for modulation of gene transcription. Thus, activators of adenylate cyclase, analogs of cAMP (8BrcAMP), or

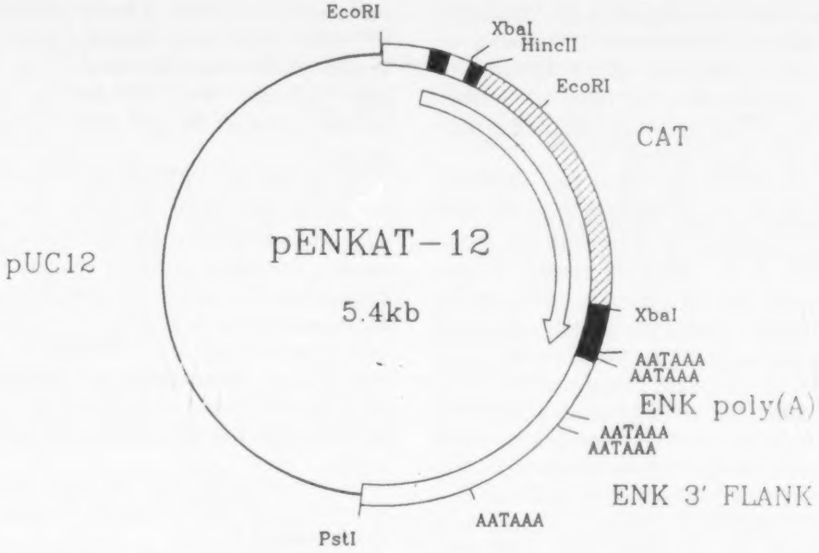

FIGURE 3. Structure of the human proenkephalin/CAT fusion gene.

phosphodiesterase inhibitors (IBMX) which prevent breakdown of intracellular cAMP may all affect gene transcription by a similar second messenger system.

When cAMP regulators were added to the media 18 hours after ENKAT-12 transfections, an increase in CAT activity was observed. 8BrcAMP (0.9 mM) alone caused a five-fold increase in CAT activity while 8Br-cAMP and IBMX (0.5 mM) together caused an 18-fold increase in CAT expression. These data suggest a clear role for cyclic AMP as a second messenger involved in mediating proenkephalin gene expression. Cholera toxin and forskolin, other stimulators of adenylate cyclase, also produced increases in ENKAT-12 directed CAT expression.

To localize the DNA sequences in the proenkephalin gene which were responsible for the cAMP transcriptional regulation, several plasmids were constructed which contained deletions or insertions in the 5′ flanking region of the human proenkephalin gene. Plasmid ENKAT B lacks the DNA sequence from −60 to −155 base pairs upstream of the human enkephalin cap site. Transfections with this plasmid gave a several-fold reduction in basal CAT activity and no induction with cAMP analogs. Reinsertion of the −60 to −155 sequence into the plasmid but in the opposite orientation restored both the basal and regulated expression. Thus, this region of the 5′ flanking sequence of the gene contains sequences required for both basal and regulated expression, and these sequences can work in an orientation independent fashion as enhancer elements in other genes.

It was also exciting to find that this region was capable of conferring cAMP regulation on a different promoter. The DNA sequence from −60 to −155 bp upstream of the human proenkephalin cap site was fused to a POMC-CAT fusion gene containing only 84 bp upstream from the POMC cap site. The POMC-CAT fusion gene expresses low basal CAT activity and shows very slight (two-fold) increases in CAT activity in response to cAMP. However, fusion of the DNA sequence from the human proenkephalin gene 5′ to the 84 bp of upstream sequences in the POMC-CAT construct showed increases of basal expression and conferred a larger (greater than 20-fold) induction by cAMP. This finding suggests that this region of the human proenkephalin 5′ flanking sequence is sufficient to confer cAMP inducibility on an intact promoter.

In order to map the exact location of the DNA sequences responsible for cAMP regulation, a series of 5′ deletion mutants have been constructed using Bal 31 exonuclease. We hope to be able to localize the regions responsible for basal activity and cAMP regulation using these deletions so that these sequences can be examined more fully with site-specific mutagenesis and used as probes to search for trans-acting proteins which may be involved in these processes.

Vaccinia Virus: Vaccinia virus has recently been introduced as a eucaryotic cloning and expression vector. There are several good reasons for this: a) broad host range of vaccinia virus which allows genetic information to be shuttled into a variety of species and cell types; and b) vaccinia is a cytoplasmic virus and therefore replicates, transcribes, and processes the vaccinia viral genes in the cytoplasm of the infected cells. Therefore, if the cDNA for a gene of interest is inserted downstream of a vaccinia promoter, it will be rapidly transcribed (within a few minutes) and expressed at high levels in the host cell cytoplasm. This system is very useful then for examining the expression of neuropeptides, such as proenkephalin, in a variety of different cell lines to address questions regarding the post-translational maturation of these proteins and the enzymes which normally catalyze the processing events.

To achieve this goal, a recombinant vaccinia virus was constructed which contains and expresses the human proenkephalin cDNA (G. Thomas, unpublished studies). Four different cell lines were infected with this recombinant vaccinia virus. Two of the cell lines, AtT-20 and GH_4C_1 (rat pituitary), contain a full complement of secretory organelles. The other two cell lines, BSC-40 (African green monkey kidney cells) and Ltk^- (mouse fibroblast), do not contain stored granules typical of secretory cells. Twenty-four hours after infection, cell extracts and culture media were collected for separation on a TSK-125 high performance liquid chromatography sizing column followed by radioimmunoassay for Met-enkephalin. BSC-40 cells infected with the recombinant virus revealed two prominent peaks of Met-enkephalin immunoreactivity (IR). The faster migrating peak eluted at the expected size for human proenkephalin (28,000 daltons). The slower migrating peak eluted with an apparent molecular weight of 16,000 daltons. Similar results were obtained with the GH_4C_1 and Ltk^- cells. The media of the BSC-40 cells were also analyzed. These results demonstrated that only the larger peak of Met-enkephalin IR was secreted from the cells and this protein was shown to be authentic proenkephalin by purification and sequence analysis.

In contrast, AtT-20 cells infected with the recombinant virus showed five major peaks of Met-enkephalin IR. The slowest migrating peak coeluted with authentic Met-enkephalin. Therefore, the AtT-20 cells are processing the proenkephalin protein to Met-enkephalin and will therefore be useful for examining the enzymes necessary for this process and for elucidating the proenkephalin processing pathway in these cells.

Conclusions

Gene transfer methods have given us the opportunity to examine the molecular mechanisms involved in the regulation of expression at almost every level: transcription, translation, processing, and secretion. It is our hope that by using a variety of gene transfer approaches to study regulation, we will be able to examine each level of regulation in detail. By then integrating the information which we have attained from each system, we hope to be able to gain a more complete understanding of the cellular mechanisms involved in the control of neuropeptide expression by hormones and neurotransmitters from the point at which these regulators interact with cell surface receptors to the activation of the intracellular cascade that leads to turning neuropeptide genes on and off.

Interactions of Alcohol and Drugs of Abuse

Monique C. Braude, Ph.D.[1]

The focus of this symposium is the discussion of a number of critical issues concerning pharmacological intervention in alcohol and drug abuse disorders. Kreek and Stimmel (1984) published an excellent overview of this topic. This paper will cover more specifically what we know at present regarding interactions of alcohol with abused substances, i.e., compounds used either therapeutically like benzodiazepines and opiates, or on the street like amphetamines, cannabinoids, and cocaine.

Interactions between alcohol and other drugs fall into three basic categories: 1) additive/synergistic: the separate effects of each drug adds to the effect of the other when taken together, 2) potentiation when the resulting effect is greater than that of each component, and 3) antagonism.

A direct interaction is the result of the pharmacologic effects of the drugs. Indirect effects include pharmacokinetic interactions (in which a drug alters the absorption, distribution, metabolism, or excretion of another) and tolerance phenomena in which a drug alters the response of the target tissue to itself or another drug. Tolerance to alcohol has been reported after repeated use. Cross tolerance between alcohol and other drugs occurs when the physiologic changes induced by alcohol, for instance, carry over to another drug such as a barbiturate and the observed effect of the second drug is diminished. Interactions between alcohol and other drugs can usually be understood in terms of one or more of these phenomena.

Why are we interested in drug interactions? The important consequences of psychotropic drug interactions for an individual and society include the following:

1) Unexpected degree of impairment in performing daily tasks associated with a serious potential for injury (driving a car, operating machinery).

2) Accidental death from overdose.

3) Increase in behavioral toxicity (cognitive functions, memory impairment, etc.).

The concomitant oral ingestion of alcohol and other drugs could theoretically affect the absorption of these drugs but information is mostly lacking in this area and the existing evidence does not point to clinically significant effects. Alcohol in the body is primarily metabolized by the liver alcohol dehydrogenase to yield acetaldehyde. Research in the last 10 years also indicates that acute and chronic administration of alcohol can inhibit the biotransformation of many drugs that are normally degraded by hepatic microsomal mixed function oxidases. The most prominent result of this alcohol-induced inhibition of microsomal enzymes *in vivo* appears to be a prolongation of the plasma life of drugs such as pentobarbital, meprobamate, amphetamines, and others—but not phencyclidine (PCP). The amount of alcohol use as well as the direction of its use over a long or short period are also important factors in drug interactions.

---

[1] National Institute on Drug Abuse, 5600 Fishers Lane, Room 10A-31, Rockville, MD 20857.

Whereas acute alcohol intoxication usually inhibits the biotranformation of drugs, the long-term ingestion of alcohol can lead to hepatic microsomal enzyme induction and produce enhancement of the formation of intermediate metabolites that may be toxic to the liver thus increasing the hepatotoxic effect of alcohol. Such appears to be the case with cocaine. Finally, alcohol can influence the elimination of other drugs indirectly by causing hepatic dysfunction and/or nutritional deficiencies.

An excellent review by Muhoberac et al. (1984) on the mechanism(s) of ethanol-drug interaction focuses on the structure/function relationship of drugs at the microsomal levels. It complements two comprehensive reviews by Sellers (1978) and Linnoila (1979) that emphasize the pharmacokinetic aspects of drug interactions with alcohol.

Interactions of Alcohol With Central Nervous System (CNS) Depressants and Benzodiazepines

Interactive effects between alcohol and CNS depressants such as barbiturates, benzodiazepines, and methaqualone are frequent. In terms of CNS depression, use of these drugs with alcohol is usually additive. With drugs which are metabolized by the hepatic microsomal enzyme system, such as phenobarbital and pentobarbital, synergism has been reported leading to increased toxicity and death in humans.

Benzodiazepines have now significantly replaced barbiturates as anxiolytics and sedative hypnotics.

Benzodiazepines and Ethanol

The most extensively studied drug interactions have been those of benzodiazepines, and ethanol. Two recent reviews (Sellers, 1982; Chan, 1984) evaluate the effects and consequences of these interactions.

As noted in the review by Sellers, ethanol and benzodiazepines interact both at the pharmacokinetic and pharmacodynamic levels in a predictable manner qualitatively or quantitatively by enhancing each other's effects. However, benzodiazepines do not seem to potentiate the effects of alcohol as much as other sedatives do.

Kinetically, acute doses of alcohol impair the disposition of benzodiazepines that are metabolized by demethylation or hydroxylation. For instance, it increases the blood levels of orally administered diazepam but not of oxazepam which undergoes glucuronide conjugation. Chronic ethanol ingestion, on the other hand, increases the clearance of benzodiazepines that are demethylated or hydroxylated.

In general, alcohol and benzodiazepines when studied alone produce sedation, impair motor coordination, reaction time, memory acquisition, retention, and recall in a dose-related manner. Many studies indicate that the acute combination of both drugs produces the same impairment at a lower dose than given separately or reveals an impairment not apparent with the control dose of the drug alone. In this enhancing effect, alcohol appears to be the dominant partner. Although alcohol/benzodiazepine interactions are considered by Sellers less important than those involving alcohol and other psychotropic drugs such as cannabinoids, neuroleptics, stimulants, and antidepressants, Chan points out that this combination is associated with drug-induced deaths, drug overdoses, traffic accidents, and fatalities.

Interestingly, a major clinical use of benzodiazepines has been in the short- and long-term treatment of alcoholics as benzodiazepines were found very effective in alleviating alcohol-withdrawal symptoms. This is now controversial as some studies have pointed out that alcoholics may be more at risk of developing benzodiazepine or alcohol/benzodiazepine dependence than the general population. There is therefore a dire need for large scale controlled studies concerning the efficacy of benzodiazepines in the long-term treatment of alcoholics.

Alcohol and Cannabinoids

Marijuana and alcohol are ubiquitous. The combined use of ethanol and marijuana in variable amounts, frequencies, and settings has become a well-established fact (Mello, 1978). Animal studies performed by Siemens (1980) in rats showed that simultaneous administration of tetrahydrocannabinol (THC) and ethanol resulted in an increased rate and magnitude of ethanol tolerance and physical dependence. Complete ethanol tolerance was established within 12 to 16 days in animals receiving both drugs, whereas only minimal ethanol tolerance or cross tolerance was detected in ethanol- or THC-treated rats, respectively, at this time.

A few studies in humans have indicated that the acute administration of THC, the primary psychoactive component of marijuana, in combination with alcohol results in enhanced impairment of physical and mental performance, more marked subjective effects such as pupil size, and a greater increase in pulse rate and conjunctival congestion compared to ingestion of either drug alone (Manno, 1971; Bird, 1980). However, the magnitude of the enhancement of the drug effects was not very great.

In more recent studies, Belgrave and Chesher (1979a) from Australia using a battery of cognitive, perceptual, and motor function tests also found that both THC and ethanol produce significant decrements in the general performance factor but there was no evidence of any interaction between THC and ethanol and the effects of a combination of both compounds were no more than additive. The same was true when this group looked at the effect of cannabidiol (CBD) with alcohol using the same battery of tests (Belgrave, 1979b). CBD did not produce any demonstrable effects either alone or in combination with alcohol. However as CBD is one of the major components of some marijuana plants, there is still the possibility that there may be a THC-CBD-ethanol interaction. Consroe (1979) reported that the combination of alcohol with CBD in humans resulted in significantly lower blood-alcohol levels compared to alcohol given alone. However, he found very few differences between the pharmacological effects of alcohol given alone or given with CBD. Hollister (1986) who has reviewed this field many times concluded that there is no more than an additive effect between the cannabinoids and alcohol (both acting as CNS depressants) and that further studies in this area may not be necessary.

Alcohol and Opiates

Concomitant alcohol and narcotic abuse is very common. More than half of the "overdose" cases with heroin or methadone are in fact cases in which concomitant abuse of alcohol has played a prominent role. Most of the work on interactions of alcohol and opiates, especially exogenous opiates, comes from the laboratory of Mary Jeanne Kreek at the Rockefeller Institute and was reviewed by her in 1984.

Several studies have shown that alcohol may have a biphasic effect on the disposition of another opioid. During chronic use of large quantities of alcohol and at times when high blood levels of alcohol are present, alcohol may inhibit the metabolism of other drugs such as methadone. But when alcohol is no longer present in the body, drug metabolism may be accelerated due to the fact that, in the chronic alcoholic, alcohol has produced an enhancement of the hepatic microsomal P–450 enzyme dependent system. The presence of chronic alcoholic-induced liver disease may result in significant alterations in methadone disposition and prevent achievement of the steady state during methadone treatment. An interesting possible interaction between the opiate antagonist, naloxone, and ethanol gave promise for using an opiate antagonist to alleviate the ethanol-induced performance impairment. However, recent studies by Mendelson (1986) using the antagonist Naltrexone to assess the efficacy of this compound in attenuating acute alcohol intoxication in humans failed to find any significant differences between reported subjective levels of intoxication and detection of alcohol effects or blood alcohol levels following Naltrexone compared to placebo administration.

Combined Abuse of Alcohol and Stimulants: Amphetamines and Cocaine

Surprisingly few studies have dealt with the interaction of alcohol and amphetamines in humans in spite of the widespread use of both. Most of the studies that have investigated the effects of combined alcohol and amphetamine use have utilized either animal or volunteer subjects rather than members of the subculture directly involved in such abuse. Although synergism between alcohol and amphetamines was demonstrated in some preclinical studies, a large majority have reported antagonism between the two. As a result of the clinical evaluation of several patients for treatment of alcohol abuse, Kipperman and Fine (1974) made an interesting finding, i.e., that the clinical histories of these patients indicated the existence of two types of abuse patterns, one primarily concerned with the effects of amphetamine and the other with the effects of alcohol; the latter type of patients using amphetamine only to help them maintain a wakeful state.

A naturally occurring alkaloid, cocaine is a powerful and rapid CNS stimulant of short duration, which has recently become a prominent and favored drug of abuse. Cocaine is rapidly hydrolyzed in the body by esterases. It may also undergo hepatic microsomal oxidation to N-dealkylated metabolites. Smith, Freeman, and Harbison (1981) have shown that pretreatment with alcohol for 5 days at first reduces the immediate mortality rate produced by a large dose of cocaine, probably through a stimulation of the monooxygenase system which speeds up the degradation of cocaine. But this process can also produce greater amounts of intermediate metabolites that are toxic to the liver and delayed mortality (1 to 7 days after cocaine ingestion) is increased. The hepatic cytochrome P–450 content was doubled in ethanol-treated animals. These observations suggest that the early toxicity of cocaine is due to the parent drug and that ethanol pretreatment provides protection by enhancing the elimination of cocaine through induction of the cytochrome P–450 system. However, the more rapid degradation of cocaine produces greater concentration of norcocaine, an N-demethylated metabolite that is more toxic than cocaine.

Interactions of Alcohol and Other Abused Substances at the Perinatal Level

Another aspect of the combined use of alcohol and abused substances that requires further attention is the effect of combined perinatal exposure to these drugs on the fetus and offspring.

It was not until recently that it was shown by Abel (1985) that alcohol produced an enhancement of marijuana-induced fetotoxicity in rodents. The combination of marijuana and alcohol caused a 100 percent fetomortality that differed significantly from vehicle treatment. These studies suggest a potential danger to pregnancy resulting from the combined use of two commonly used drugs which is far greater than that associated with the use of either drug alone. This is especially significant in view of a recent study by Lex, Griffin, Mello, and Mendelson (1986) on concordant alcohol and marijuana use in women. This study shows strong correlations between alcohol and marijuana use, with the female heavy marijuana smokers reported drinking significantly more alcohol than female light marijuana smokers.

Epidemiology studies on the patterns of prevalence of combined use of alcohol and abuse substances by pregnant women are definitely called for.

Conclusion

In summary, most of the abused compounds interact with alcohol in a predictable manner. What is important to remember is that the pharmacokinetic and pharmacodynamic interactions of a given drug with alcohol is in part dependent on the length of the individual exposure to alcohol. The end response may be enhanced in the acutely intoxicated individual who does not have a history of alcohol abuse. Conversely, it may be diminished in the otherwise physically healthy but alcohol-dependent individual.

In general, appreciation of alcohol-drug interactions should provide a useful basis for the management of alcoholic patients and the prevention of accidental overdoses.

Epidemiologic and Clinical Findings of Significance to the Design of Neuropharmacologic Studies of Obsessive-Compulsive Disorder

Steven A. Rasmussen, M.D., and Ming T. Tsuang, M.D., Ph.D.[1]

Over the past decade, neuropharmacologists have devoted increasing effort to understanding the neurobiologic basis of anxiety. Until recently, clinical researchers have focused their attention almost exclusively on panic disorder. Obsessive-compulsive disorder (OCD) has been relatively neglected, due to the general perception that it is a rare illness with a poor prognosis. This belief has been challenged by recent epidemiologic and treatment outcome studies that have set the stage for a resurgence of interest in OCD over the next decade. Recent data from the Epidemiologic Catchment Area (ECA) survey suggest that the disorder is 50 times more common than was previously believed (Myers et al., 1984; Robins et al., 1984). The average patient with OCD can currently look forward to a 70-percent chance of significant clinical improvement due to advances in behavioral and pharmacologic treatments developed over the past 15 years (Insel & Murphy, 1981; Marks, 1981). Newer pharmacologic treatment strategies for the treatment resistant patient have also begun to show increasing promise (Rasmussen, 1984).

When we initiated this project, we were surprised to discover that there had been no large scale phenomenologic or epidemiologic study of OCD in the last 20 years (Rasmussen and Tsuang, 1984). This paper describes our experience in establishing an obsessive disorders clinic over the past 2½ years. Preliminary results of a clinical descriptive study of a subgroup of these patients are described. Problems facing researchers interested in studying the neurobiology of the disorder are reviewed, and future clinical and epidemiologic studies that should proceed in concert with neuropharmacologic and treatment outcome studies are suggested.

Given its intrinsic clinical and phenomenologic interest, why has research in OCD been so limited up until now? Undoubtedly, the single most important factor has been the mistaken belief that OCD is a rare illness. This belief was based on a series of followup studies initiated in the 1950's and 1960's. These studies were consistent in finding that the incidence of OCD in psychiatric inpatient and outpatient settings was only 1 to 2 percent (Rasmussen and Tsuang, 1984). In our own review of over 10,000 psychiatric charts in the Rhode Island, Southeastern Massachusetts area, only 0.6 percent of inpatients and 1.8 percent of outpatients were found to have OCD. Most investigators felt that these figures significantly underestimated the disorders prevalence in the general population. In 1953, Rudin estimated the disorders prevalence in the general population at 0.5 percent. In 1984 preliminary results from the ECA were published. Among the most striking findings were the high lifetime, 2.5 percent (Robins et al., 1984), and 6-month point prevalence rates (1.6) of OCD (Myers et al., 1984).

If these figures are valid, it would make OCD the fourth most common psychiatric disorder, twice as prevalent as schizophrenia or panic disorder in the general population, and 50 times more common than Rudin's 1953 estimate. Critics of the ECA study have noted that the structured interview schedule questions for OCD may not have used a strict enough criterion for measuring significant impairment in social and occupational functioning. There is also debate about whether the severity of illness was reliably measured. Both of these would result in the inclusion of subjects who did not have clinically significant illness, leading to an overestimate of the true prevalence. There is a need for a study that compares a large OCD population from a typical clinical sample with an ECA OCD cohort using identical structured instruments. Future funding for biologic research and treatment outcome studies will be dependent on proving that the true prevalence and clinical significance of the illness are greater than has generally been held up until now.

Over the past 2½ years we have identified over 150 patients who meet criteria for DSM-III-R OCD in the Rhode Island, Southeastern Massachusetts area. Our success in recruiting this size sample in a 2½-year period supports our belief that the disorder is not rare. Our sample is representative of a clinical population that would typically present to a primary or secondary care setting. To this end, none of the patients were recruited by advertisement or articles in the media and all had presented to a physician or mental health professional for their obsessive compulsive (OC) symptoms. Unlike previous OC samples at the Maudsley Hospital or NIMH, 45 percent of this group had never been hospitalized.

We began to recruit the sample by reviewing the charts of all neighboring hospitals and mental health centers between 1965 and the present for an admission or discharge diagnosis of OCD. We found that most patients who were contacted, even up to 10 to 15 years after hospitalization, continued to suffer from significant symptoms, and were more than willing to participate in the research. In addition, talks were given at all the hospitals and mental health centers in the area, as well as at the local branch of the APA. Many patients came from direct physician referrals. Treatment resistant patients were offered pharmacologic or behavioral treatments that were not available elsewhere in the community.

We began to study the heterogeneity of OCD and its coexistence with other psychiatric disorders in a subgroup of 44 patients who meet DSM-III-R criteria for OCD by administering a semistructured interview to each of the probands (Rasmussen and Tsuang, unpublished). The interview covered demographics, obsessive and compulsive symptoms, course of illness, a checklist of symptoms for depression, psychosis, other anxiety disorders and personality disorders, and family history. We attempted to answer the following questions: (1) is OCD a heterogeneous diagnosis and, if so, can it be divided into homogeneous subgroups; (2) what are the difficulties one can encounter in the differential diagnosis of OCD; and (3) what are the disorders that are likely to coexist with

TABLE 1. Description of the Obsessive-Compulsive Sample ($n = 100$).

Sex	(%)	Race	(%)
Male	38.0	White	93.0
Female	62.0	Black	7.0
Mean Age at Admission	(%)	Religion	(%)

Single	40.0	Other	18.0
Ever Married	55.0		
Ever Divorced	5.0		

OCD? Demographic characteristics of the sample are given in Table 1.

Can OCD be subdivided by symptoms or course of illness? The most common obsession, found in 24 (55%) of the patients, was fear of contamination. This obsession took many forms, among the most common being the fear of unseen dirt, germs, poisons, or toxins. Included in this group were several patients who developed morbid fears of potentially carcinogenic chemicals such as insecticides or asbestos. Twenty-five (57%) of the patients had cleaning rituals. Of those patients with contamination obsessions 83 percent also had cleaning rituals. Thirty-five (80%) of the patients had checking rituals, and nine (21%) had counting rituals. The next most common obsessive thought, present in 22 (50%) of the patients, were aggressive obsessions, typified by fears of harming or cheating others on purpose or inadvertently. A young mother who was obsessed with the fear that she would strangle her 6-month-old baby, a nurse who felt she would give a patient the wrong medication on purpose, and a mother who felt compelled to buy whatever she touched while shopping because she thought she had damaged it are a few illustrative examples. Eighty-four percent of the patients with aggressive obsessions also had checking rituals.

Thirty-two percent of the patients complained of sexual obsessions. These were most commonly fears of acting on sexual impulses that went against their value system, or fears of sexual perversions. As with the patients with aggressive obsessions, these patients were often unable to make a clear distinction between having an unacceptable thought and acting on it. Fifteen (68%) patients with aggressive obsessions also had fears about their sexual impulses. As a group the patients with sexual obsessions were usually preoccupied with guilt, at times of near delusional proportions. The patients with sexual obsessions followed in our clinic tended to have internal conflicts between their sexual and aggressive impulses and their value systems. They tended to have difficulty in expressing their anger and sexuality and were almost always neurotic as opposed to psychotic.

Sixteen (36%) of the patients had obsessive thoughts that involved what we have termed the need for symmetry or exactness. Examples would be the man who felt he had to walk through an office door exactly in the middle and sit at an 90° angle to the therapist, a woman who had to lean objects at just the right angle before she could complete an action, and a man with Tourette's syndrome (TS) who, if he had a certain number of tics on one side of his body that were involuntary, had to "even them up" with the same number of voluntary movements mimicking the tics on the other side. Patients could usually not express the reason behind these obsessions, other than a fear that something bad would happen if they did not "even things up." Many patients with this symptom also had developed checking and counting rituals. Most were perfectionistic and had had compulsive personalities from an early age. This obsession was significantly more common in men than women ($\chi^2 = 8.05, f = 1, p < .05$).

Fifteen (34%) of the patients had somatic obsessions. Their lives were dominated by incessant, compulsive checking rituals carried out to reassure them that they did not have a serious illness. Illustrative examples are the surgeon who was obsessed by the thought he had a hernia and who was compelled to examine himself continually to the point of creating an inguinal ulceration, and the woman who was compelled to examine her breasts up to 100 times a day to check that she had not developed cancer. Almost all of these patients had other associated obsessions or compulsions. Of the 15 patients with somatic obsessions, 73 percent had checking rituals. Six (14%) of the patients had obsessions classified as "other."

The most common compulsions were checking, cleaning, and counting rituals. Eighteen (41%) of the patients exhibited more than one ritual, and 26 (59%) exhibited multiple obsessions. Only two (4.5%) of the patients had obsessions with no compulsions, and only one (2%) had rituals without obsessions. Patients did not always carry the same symptoms throughout the course of their illness. Thus, patients, whose clinical picture was dominated by aggressive and sexual obsessions associated with checking rituals during an exacerbation of illness at one time could develop fears of contamination and handwashing rituals during another episode.

Each patient's course of illness was determined as falling in one of three categories: episodic, continuous, or deteriorative. Four patients had the onset of their illness within the year of admission. Therefore, these patients were classified as having acute-onset OCD. The remainder of the group had a mean ± difference between age of onset and age at interview of 15.5 ± 10.12 years. Only one (2%) of the patients had an episodic course, 37 (84%) were classified as having a continuous course, and six (14%) were classified as having a chronic deteriorative course. Many of the patients with a deteriorative course had given up resisting their obsessive or compulsive symptoms and had a tendency to manifest severe anxiety that did not habituate with flooding or desensitization techniques. Eleven (25%) of the patients could identify an environmental precipitant that appeared to trigger their illness and 31 (70%) could not. Data on precipitants were not available for two (5%) of the patients. Increases in responsibility such as the birth of a child, promotion to a new job, or significant losses such as the death of a family member or loss of a job were the most common precipitants noted. Almost all of the patients reported an increase in obsessive compulsive symptoms coincident with stressful life events.

While the most obvious way of subdividing the disorder is by type of obsessions, compulsion, or by course of illness, there are other possibilities that should be examined more closely with a larger sample in the future. Some of these include: (1) whether the OC symptoms are brought on by an internal or external cue, i.e., the fear of an internal drive versus an external object or situation; (2) whether the patient has insight into his illness and manifests high resistance towards the obsessions and compulsions versus poor insight and low resistance; and (3) those with impulsive vs. compulsive personality traits.

The development of valid and reliable exclusion criteria presents another dilemma for those interested in studying OCD, due to the extensive overlap of OCD with schizophrenia, major depression, and other anxiety disorders. Coexisting psychotic and affective symptoms may interact with obsessions and compulsions, thereby influencing the results of treatment outcome and neurobiologic studies. For example, it has been reported that OC patients resistant to standard behavioral treatment almost always have significant coexisting affective or psychotic symptoms (Foa, 1979). The differential diagnosis of OCD includes major depressive disorder, schizophrenia, panic disorder, phobia, (TS), hypochondriasis, and post-traumatic stress syndrome.

It can be extremely difficult to distinguish the OCD proband with prominent obsessions (e.g., somatic) from the patient with a primary major depression with ruminations. While guilt, obsessions, ambivalence, and anhedonia are clinical features of both OCD and major depression, true compulsions are rarely seen in the latter. Patients with a major depression also tend to have a later age of onset and are more likely to have an episodic course with normal intercurrent functioning. Patients with major depression as well as patients with OCD have a high frequency of dexamethasone nonsuppression. Both groups have abnormal REM latencies (Insel et al., 1985) and a negative response to yohimbine challenge (Rasmussen et al., unpublished). While both disorders respond to clomipramine (CMI), major depression also can be treated successfully with ECT, other tricyclics, and MAO inhibitors.

Two recent papers have described a subgroup of OCD patients who present with psychotic features (Solyom et al., 1985; Insel et al., unpublished). Separating patients suffering from severe OC symptoms who have little insight into their obsessive thoughts and no resistance from delusional schizophrenics with compulsions can also be difficult at times. About 10 percent of schizophrenics have true compulsions. Both illnesses have a chronic deteriorative course and a similar age of onset. Hallucinations and a formal thought disorder occur rarely in OCD. As a rule, schizophrenics show a more favorable treatment response to neuroleptics than obsessive compulsives with psychotic features.

Similarities between OCD and panic disorder with agoraphobia include the fact that both syndromes are characterized by high levels of generalized and anticipatory anxiety as well as a chronic waxing and waning course. They have a similar age of onset and sex distribution. Both disorders have a high incidence of coexisting depression, and both illnesses respond well to behavioral treatment. Patients with both disorders have episodes of panic anxiety. However, these episodes are triggered by thoughts or compulsions in OCD patients and can usually be distinguished from spontaneous attacks. While panic level anxiety tends to result in avoidance in probands with panic disorder, it causes an increased frequency of compulsions in OCD.

Several authors have commented on the significant incidence of obsessions and compulsions in patients with TS and their first degree family members (Nee et al., 1980; Pauls et al., 1984). Distinguishing a complex tic from a compulsion can be difficult. TS patients tend to suffer from aggressive and sexual obsessions. They also frequently exhibit the need for symmetry. In spite of some similarities between the illnesses, important distinctions exist. Phenomenologically, if you ask TS patients what it feels like to withhold a tic, they will describe a feeling of increasing tension that rapidly builds to a crescendo. They tend to describe that tension in physiologic terms (e.g., it's like I have to sneeze and I can't). In contrast, OCD probands, if asked what it feels like to stop a compulsion, will report that the feeling of increasing tension is inextricably linked to anxiety. In addition, TS has a male predominance and an earlier age of onset. TS is usually neuroleptic responsive while OCD is not. In contrast, CMI has been of little therapeutic benefit in TS but remains the best pharmacologic treatment for OCD.

Inclusion or exclusion of some or all of these patients who present diagnostic dilemmas will have an important effect on the outcome of neurobiologic and treatment efficacy studies. Although the inclusion of these patients may result in increased variance, excluding them may limit our knowledge of how these disorders interrelate.

The frequency of coexisting Axis I psychotic disorders in the sample we have interviewed is given in Table 2. One third of the

TABLE 2. Coexisting Psychiatric Symptoms and Diagnoses.

Depressive Symptoms (*n* = 44)	(%)	Psychotic Symptoms (*n* = 44)	(%)
Depressed mood	81.0	Delusional	5.0
Inadequacy	63.0	Hallucinations	4.0
Hopelessness	52.0	Thought Disorder	0
Secondary DSM-III Diagnoses			
Axis I	(%)	Axis II	(%)
Major depressive disorder	30.0	Compulsive	54.6
Simple phobia	6.8	Histrionic	9.1
Tourette's syndrome	4.5	Schizoid	6.8
Panic disorder	4.5	Dependent	4.5
Pervasive developmental	2.3	None	34.0
Alcohol abuse	2.3		
Mixed substance abuse	2.3		
None	47.0		

Lifetime History of Associated DSM-III Anxiety Disorder

Diagnosis	Simple Phobia	Social Phobia	Separation Anxiety	Panic Disorder	Agoraphobia	Tourette's Syndrome
%	27.3	18.2	17.6	13.8	8.9	6.8

patients had a major depressive disorder on admission. The next most common secondary diagnoses were simple phobia, TS, panic disorder, and substance abuse. Other Axis II diagnoses included histrionic, schizoid, and dependent personalities. Lifetime diagnosis of coexisting anxiety disorders suggests that OCD patients have an increased vulnerability to almost all of the other anxiety disorders. The incidence of lifetime major depression was 55 percent, a figure close to that seen for lifetime major depression in panic disorder.

One can also look at the coexistence question by asking how many patients with other primary psychiatric diagnoses have significant OC symptoms. Breier et al.'s (unpublished) interview study has shown that about 15 percent of patients with panic disorder have significant obsessions or compulsions. Chart review studies of the Iowa 500 (Rasmussen and Tsuang, unpublished), Chestnut Lodge Followup study (Fenton and McGlashan, unpublished), and records from the Maudsley Hospital (Rosen, 1958) have all shown that about 10 percent of schizophrenics have obsessions or compulsions. Several authors have found that a high percentage of TS patients have coexisting OCD (Nee et al., 1980; Pauls et al., 1984). Gittleson (1966) studied OC symptom patients who were psychotically depressed, while Videbach (1975) reported on depressed patients with compulsive personality traits. The incidence of obsessions and compulsions in a clinical sample of major depression is unknown. A controlled interview study that is designed to determine the frequency of obsessions and compulsions in representative clinical samples of patients with the above diagnoses has yet to be done.

The high frequency of coexistence between OCD and other psychiatric disorders is substantiated by findings from the ECA study (Boyd et al., 1984). The odds ratio for the coexistence of OCD with other DSM-III/Diagnostic Interview Schedule psychiatric disorders in subjects who were selected to represent the general population were as follows: panic disorder 20.6, schizophrenia 12.3, agoraphobia 10.9, major depression 10.8, and simple phobia 9.7.

In summary, several problems have limited neurobiologists' interest in OCD. The belief that OCD is a rare illness has recently been brought into question by data from the ECA study that suggests that OCD is the fourth most common psychiatric disorder. The heterogeneity of the illness, difficulties in establishing valid and reliable exclusion criteria, and OCD's coexistence with other psychiatric disorders all can directly or indirectly influence the results of biologic and treatment outcome studies. Several other problems face the neuropharmacologist who wishes to study OCD. First, psychosocial factors probably play an important role in OCD's pathogenesis. Our preliminary observations support previous data suggesting that the strictness of parental and religious upbringings may play an important role. This makes it more difficult to separate the biologic and genetic factors that may be involved in pathogenesis for OCD in comparison to an illness like panic disorder. Second, the presence and severity of OC symptoms are often dependent on environmental context. For example, it is not unusual for an OCD patient to be 2 hours late to a challenge procedure because he got stuck checking when leaving his house in the morning for his appointment. However, upon reaching the hospital where the test is to take place, he may report that he is asymptomatic and is not having any difficulties with obsessions and compulsions whatsoever. The dependence on environmental context can also be very useful, as behavioral challenges with phobic objects can be utilized to reliably elicit anxiety and compulsive behavior. Third, the degree of state anxiety or depression may have an important influence on the expression of OC symptoms. The importance of collecting ratings of anxiety and depression along with OC ratings in pharmacologic studies is clear. A fourth problem is the lack of a valid and reliable OC rating scale that adequately measures change over time. Finally, there is no short acting pharmacologic agent such as yohimbine or lactate for panic disorder that will reliably reproduce or diminish OC symptoms.

Future studies of the neuropharmacology of OCD need to be completed in tandem with clinical and epidemiologic studies that are designed to overcome or minimize some of the difficulties enumerated above. A more careful characterization of the heterogeneity of the illness and its coexistence with other psychiatric disorders in a large OCD sample is needed. It would be equally important to determine the incidence and significance of OC symptoms in panic disorder, schizophrenia, major depression, and TS. A comparison between a large clinical population and a cohort of OCD subjects identified in the ECA study using identical structured instruments is necessary to determine the true prevalence rate of the disorder in the general population. A careful controlled family study is needed to help determine the relative contribution of genetic and psychosocial factors to the pathogenesis of the illness. Finally, a prospective followup study of the children of adult patients in this sample would help to provide information about the natural history, high risk factors, and pathogenesis of OCD.

A Possible Genetic Relationship Exists Between Tourette's Syndrome and Obsessive-Compulsive Disorder

David L. Pauls, Ph.D.,[1] James F. Leckman, M.D.,[1] Kenneth E. Towbin, M.D.,[1] Gwendolyn E.P. Zahner, Ph.D.,[1] and Donald J. Cohen, M.D.[1]

The diagnostic convention of DSM-III excludes the diagnosis of obsessive-compulsive disorder (OCD) in the presence of Tourette's syndrome (TS). However, prominent obsessive-compulsive symptoms (OCS) have been reported in TS patients from as early as 1885, when Tourette published his first descriptions (Tourette, 1885). Other reports (Meige & Feindel, 1907; Kelman, 1965; Fernando, 1967; Morphew et al., 1969; Nee et al., 1980; Jagger et al., 1982; Montgomery et al., 1982; Stefl, 1984) have suggested that the prevalence of OCS among TS sufferers has increased, with several large surveys reporting ranges from 55 to 74 percent (Jagger et al., 1982; Montgomery et al., 1982; Stefl, 1984). This represents a significant increase when compared to a reported population prevalence of 0.05 percent to 2.0 percent for OCD (Rudin, 1953; Robins et al., 1984). In OCD, 50 percent of patients will have the onset prior to age 25 and incidence peaks between ages 10 to 14 (Black, 1974). This is in contrast to OCS in TS which appears to increase in incidence as duration of illness increases (Montgomery et al., 1982). The present study is an attempt to look more closely at the relationship between OCS and TS by examining first-degree relatives of TS patients for the presence of OCS as well as tics. The proposed hypothesis is that TS and OCS are etiologically related and that OCS may be an alternative expression of the same etiology responsible for the expression of TS itself.

Methods

This study is part of an ongoing family study of TS. The methods of the family study have been described in an earlier publication (Pauls et al., 1984). Briefly, subjects were randomly ascertained from the Connecticut TS Association membership. After obtaining informed consent, the diagnosis of TS was verified by a semi-structured interview instrument which also screens for all major psychiatric disorders including OCD. An instrument devised by Carey was also administered by direct interview to further screen for OCS in all cases. For probands under age 16, parents were interviewed about their children. After obtaining permission, all first-degree relatives were contacted and, if they consented to participate, interviewed with the same instruments. Ninety-five percent of first-degree relatives were interviewed directly. Family history reports were obtained from each interviewed family member about each other family member. Best estimate diagnoses (Leckman et al., 1982) were made on each family member from all available data obtained. Diagnostic estimates were dichotomized according to the level of certainty. For the purposes of data analysis, "definite" and "probable" TS, Chronic Multiple Tics (CMT), and OCD diagnoses were combined in one group, while "possible" and "no" diagnoses were considered as unaffected.

In this study, OCD diagnoses were based on inclusionary DSM-III criteria; that is, the presence of obsessions or compulsions were sufficient to be awarded the diagnosis, so long as concomitant major depression, schizophrenia, or other major neuropsychiatric disorder was not also present. The exclusionary criterion in the presence of TS was dropped. Respondents described a range of obsessional and compulsive symptoms all having the basic features of being recognized as senseless, psychological in origin, or originating from the respondent, and were involuntary, insuppressible, clearly disruptive, unpleasant, and gave rise to some, though variable, degree of resistance.

Results

The subjects of the current report are 27 probands and their 103 first-degree relatives. Of the probands, 14 of 27 (51.8%) met criteria for both TS and OCD. The TS with OCD probands (TS + OCD)were clinically and demographically indistinguishable from the probands without OCD (TS−OCD) except that the TS + OCD probands had a mean age higher than the TS−OCD probands, 25.0 years vs. 16.5 years respectively. In addition, TS + OCD probands were on average lower in socioeconomic status (SES) according to the Hollingshead Scale ($p < 0.07$). On other demographic features (sex, marital status, religion, and education) the subgroups were essentially identical. On clinical features the two subgroups were also similar. There were no differences in tic frequency, tic disruption, age of onset, age of maximal severity, and, importantly, medication history.

By sub-dividing the 103 first-degree relatives according to proband diagnoses, comparisons could be made between those who were relatives of TS + OCD and TS - OCD probands. Figure 1 compares the frequency of the mutually exclusive categories of TS, Chronic Multiple Tics (CMT), and OCD among the relatives of TS + OCD and TS - OCD probands. In this study: 1) the rate of "definite" and "probable" OCD among these relatives (OCD + [TS + OCD] + [CMT + - OCD]=22/103, 22.3%) is elevated beyond what is expected for the general population, pected for the general population, whether the proband had OCD or not, and 2) the diagnosis of OCD is as prevalent among relatives of TS−OCD probands (12/45, 26.7%) as among those who were related to probands with TS + OCD (11/58, 19.0%). The interpretation of these data suggests that the risk of developing OCD in these relatives was increased and independent of whether the proband had OCD. The high frequency of "OCD only" among relatives also suggests that some OCD may be etiologically related to TS.

Discussion

The high frequency of OCD diagnoses in first-degree relatives of probands with TS−OCD and the development of OCD without tics in first-degree relatives of TS−OCD probands point to an etiologic relationship between TS and OCD. However, several weaknesses could call such an interpretation into question. Foremost among these is the difficulty in making accurate diagnoses of OCD. As several authors (Rachman et al., 1980; Rachman et al., 1978;

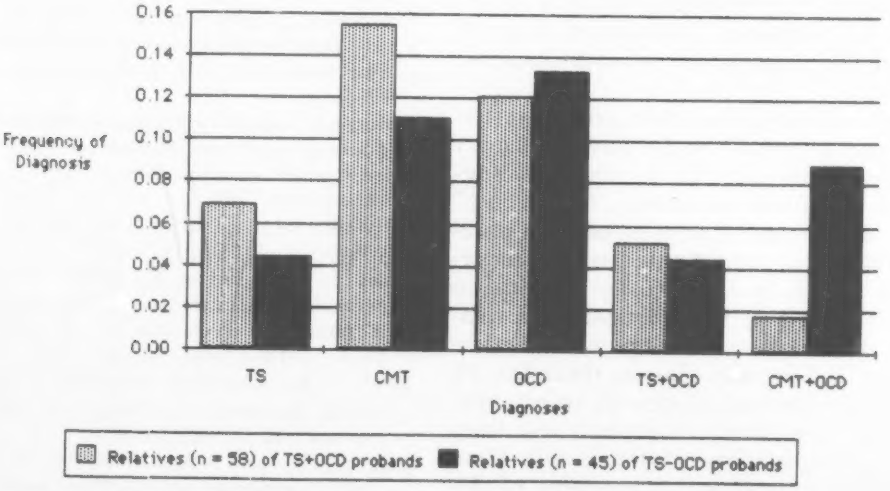

FIGURE 1. Frequency of diagnoses among first-degree relatives ($N = 103$).

Philpott, 1975; Insel, 1982) have pointed out in discussions of the epidemiologic and treatment literature on OCD, the response to a semi-structured questionnaire is not identical to a clinical diagnosis of OCD, and it is likely that occasional obsessions are normal phenomena (Rachman et al., 1980). Most of the disagreements appear to stem from disputes which are either over diagnostic criteria or over the validity of the methods used to ascertain symptoms. In this project the risk of over-estimating prevalence was lessened by the "best estimate" methodology, including in the diagnostic process interview data from family members about each subject and a specific self-rated instrument developed by Carey (unpublished), designed to provide detailed information about possible OCS. Descriptions provided by family members about each subject are of substantial assistance in making diagnostic decisions, especially when subjects are equivocal. When family members reveal that behaviors are carried to extremes infringing on day-to-day functioning, then OCD diagnoses become more credible. Even so, it must be acknowledged that a consensus on methods for accurately diagnosing OCD has not been reached.

What is particularly striking, nevertheless, is that even if these criticisms are taken into account, the rates of OCD found in this study are significantly increased when compared to those from the Epidemiologic Catchment Area Study, in which similar methodology was employed. The frequency of OCD in relatives of TS probands is increased 9 to 13 times over the population estimate obtained from the ECA.

Where previously it has been proposed that OCS are late symptoms in the natural history of TS, the findings of this family study suggest that, in some instances, "OCD only" could be an alternative expression of a putative TS gene. It is remarkable that the recurrence risk for OCD was virtually identical to that for TS itself in these first-degree relatives and that subjects developed OCD without TS or CMT at rates close to those for TS only. Work is currently underway to examine whether the hypothesis raised by these findings strengthen evidence for a simple Mendelian dominant mode of transmission of this complex behavioral disorder, as proposed by several other investigators (Kidd et al., 1982; Comings et al., 1984; Devor, 1984). These findings also suggest that there may be a TS-related form of OCD. Further efforts are, therefore, needed to characterize such features as the symptoms, course, and treatment response of the OCS observed in TS families. The study of the "OCD-only" relatives is of particular interest in this regard.

If these findings are replicated, there are several important implications for OCD research. The most important is the need to reevaluate the assumptions about etiologic homogeneity. If OCD is heterogeneous, methodologic changes in OCD studies will be necessary. Consideration of co-morbid conditions during diagnosis and allocation of subjects and the routine implementation of strategies to make accurate psychiatric diagnoses in relatives are imperative in any future studies. Findings from previous investigations about heredity, phenomenology, and treatment response may need to be re-evaluated in the light of a possible discrete etiologic subgroup.

Role of the Serotonergic System in the Postmortem Analysis of Suicide

Michael Stanley, Ph.D.,[1*] J. John Mann, M.D.,[2] and Lee S. Cohen, M.D.[3]

Suicide is a major cause of death in the United States (National Center for Health Statistics, 1979). Major efforts are underway to examine the personality, psychosocial, and biochemical correlates of this potentially preventable form of death; antemortem and postmortem studies are two of the biochemical parameters currently under investigation to examine their role in suicide. Experimental evidence derived from several research groups has suggested an association between suicidal behavior and the serotonergic system.

The following review will examine early and currently available postmortem data on the serotonergic system. This will include work on serotonin (5HT). Examination of receptors studies in this system will include 3H imipramine and $5HT_2$ binding sites, 5-hydroxyindoleacetic acid (5HIAA), and the degradative enzyme monoamine oxidase (MAO) as they pertain to postmortem suicidal research.

The advantages of human postmortem neurochemical studies must be balanced against those disadvantages which are inherent in these investigations. In postmortem research there are numerous confounding variables that may contribute to inconsistencies within a study or across studies. In this review we will assess the impact of the variables age, postmortem interval, and regional brain dissection on several of the neurochemical measures described above.

MAO

5HT is a substrate for MAO-A, an enzyme system that has been investigated in postmortem research. Three studies have examined postmortem MAO activity in suicide victims.

One study reported no differences in MAO activity compared with controls (Grote et al., 1974). A second study found reduced MAO activity in patients where the suicide was associated with alcoholism but not in depressives

without a history of alcoholism (Gottfries et al., 1975). These studies, however, both include a significant proportion of patients who had died by carbon monoxide poisoning or drug overdose, which may have altered this enzyme's activity. They also employed a single substrate concentration, a method that is less informative and less sensitive than enzyme kinetic studies.

Our group assayed MAO-A and B in the frontal cortex of suicide victims and controls (Mann & Stanley, 1984) using labeled 5HT and phenylethylamine (PEA) as substrates for MAO-A and B respectively. Suicide methods in this study were generally by violent means with the exception of one overdose. There were no significant differences between the suicide and control groups with respect to factors such as age, sex, and postmortem interval. The results of our kinetic study show no significant difference between the groups for either substrate (5HT or PEA) with respect to maximal velocity *(V_{max})* or affinity *(K_m)*. There was a significant positive correlation between age and MAO-B V_{max} for both groups. There was no correlation between postmortem interval and MAO enzyme kinetics.

Our series of suicide victims was distinguished from those of other studies of brain MAO in suicide largely because we excluded those who died by overdose, thereby avoiding the potential problem of drug effects contaminating the results. Our data suggest that the reported lower brain MAO activity in alcoholic suicides, if confirmed, may be related primarily to alcoholism rather than suicidal behavior.

Serotonergic System

Initial postmortem suicide studies typically measured 5HT and 5HIAA in brain stem areas where serotonin cell bodies are concentrated in the raphe nuclei. Of note is that, in those studies where information was available, approximately 50 percent of the suicide victims carried a diagnosis of a major depressive episode, the remaining cases carried diagnoses of alcohol abuse, adjustment disorder with depressed mood, schizophrenia, or a personality disorder (Shaw et al., 1967; Cochran et al., 1976; Beskow et al., 1976; Korpi et al., 1983), again suggesting that the altered 5HT and 5HIAA levels were primarily associated with suicidal behavior rather than depression per se.

A total of 11 studies have investigated levels of 5HT, 5HIAA, or both in suicide victims. Significant reductions in levels of 5HT, 5HIAA, or both in suicide victims have been reported in eight of the aforementioned studies. Four of the 11 mentioned studies report no significant change in levels of 5HT or 5HIAA in suicide victims (Table 1).

In all the foregoing studies, however, factors such as method of suicide, i.e., drug overdose, carbon monoxide poisoning, extensive postmortem delay, and lack of appropriate age-matched control groups may affect the interpretation of these studies. These variables may also account in part for the lack of uniformity of findings among these postmortem studies.

(3H) Imipramine Binding

Imipramine binding has been shown in animal experiments to be associated with presynaptic serotonergic nerve terminals (Brunello et al., 1982). These binding sites have been characterized on platelets and various regions of the brain. Some of the additional experimental evidence linking imipramine binding with 5HT is that 1) radioautography studies of 3H imipramine binding sites

show distribution-similar serotonergic terminals (Rainbow et al., 1982), 2) chemical and electrolytic lesions of the raphe nucleus cause a significant reduction in serotonin level and in the number of imipramine binding sites (Brunello et al., 1982), 3) the use of an irreversible ligand results in reduced 3H imipramine binding and serotonin uptake, (Rehavi et al., 1981), 4) the potency of antidepressant drugs to inhibit serotonin uptake is significantly correlated with their potency to inhibit 3H imipramine binding (Paul et al., 1981), 5) serotonin is the only neurotransmitter known to inhibit 3H imipramine binding (Paul et al., 1981; Langer et al., 1980), and 6) there is a similar pharmacologic profile between brain and platelet 3H imipramine binding sites (Rehavi et al., 1980).

Initial studies of imipramine binding in the platelets of patients with a major depressive episode have indicated decreases in the number of binding sites (Langer et al., 1983). The combined association of imipramine binding with 5HT function as well as the significant reduction in binding density in depressives suggests a possible alteration in imipramine binding in suicide victims.

To test this hypothesis our group examined imipramine binding in the brains of suicide victims and controls (Stanley et al., 1982). In this study there were no significant differences between the two groups with respect to age, sex, or postmortem interval. Additionally, the mode of suicide studied in the suicides and controls was of a sudden and violent nature, e.g., gunshot wound, jumping from height, and hanging.

Our findings indicate a significant reduction in the number of imipramine binding sites (B_{max}) (Figure 1) with no difference in binding affinity (K_d) in suicide victims as compared with matched controls.

These results are consistent with the accumulating evidence suggesting the involvement of 5HT in suicide. Specifically, reduced imipramine binding (associated with presynaptic terminals) may be indicative of reduced 5HT release and would be in agreement with those reports of reduced postmortem levels of 5HT and 5HIAA in suicides cited above.

Additional work in imipramine binding has shown significant decreases in this parameter in completed suicides (Paul et al., 1984; Crow et al., 1984) and in depressed patients who died from natural causes (Perry et al., 1983). One study, however, indicated increased imipramine binding in completed suicides (Meyerson et al., 1982).

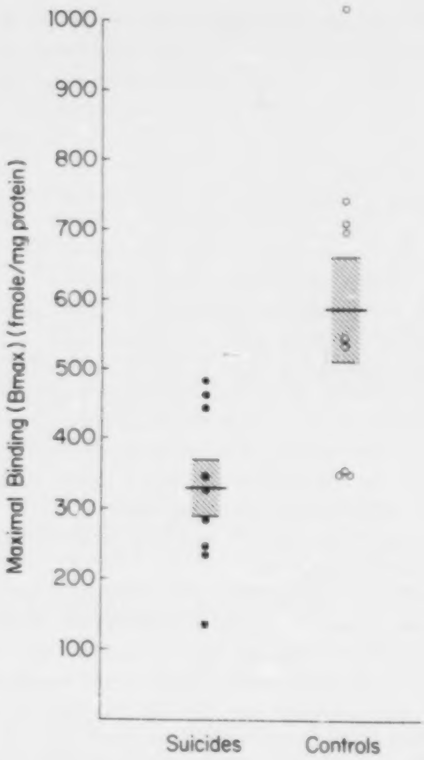

FIGURE 1. Suicide victims show a significant reduction in imipramine binding sites as compared with controls with no difference in binding affinity.

In addition to examining presynaptic neurotransmitters and receptor sites our group has studied postsynaptic 5HT binding sites using ^{3}H spiroperidol (specifically 5HT$_2$ receptor) (Stanley, Mann, & Gershon, 1983).

In our study we found a significant increase in the number of 5HT$_2$ binding sites with no change in affinity (Figure 2) in patients who committed sudden, violent suicide, i.e., gunshot wound, hanging, trauma from falling and stabbing, as compared to controls when matched for age, sex, and postmortem interval. This is consistent with an upregulation of this site in response to previously mentioned decreases in levels of 5HT, 5HIAA, and imipramine binding sites.

The finding of raised numbers of $5HT_2$ (postsynaptic) binding sites in the frontal cortex of suicide victims further supports the involvement of 5HT in suicidal behavior. Further work (Owens et al., 1983) in nonmedicated suicide victims compared to controls reported a trend towards an increase in $5HT_2$ binding with no difference in $5HT_1$ receptors; one study showed no change in $5HT_1$ or $5HT_2$ receptors (Crow et al., 1984).

These combined findings of decreased imipramine binding and increased $5HT_2$ binding are consistent with a decrease in the utilization of 5HT in suicide victims (Table 2).

In view of the above data we may postulate that the serotonergic system is altered as evidenced by changes in 5HT and 5HIAA levels, imipramine binding sites, and 5HT receptor binding sites in suicide victims as compared with controls.

However, as previously indicated in postmortem tissue analysis, a number of intervening variables such as age, postmortem interval, and regional brain dissections may have a significant impact on the above measures of serotonergic functioning in suicide victims. The following is a review of the role of these factors.

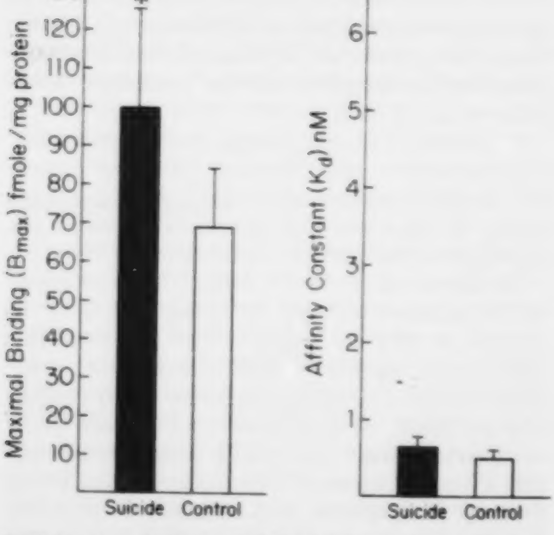

FIGURE 2. Number of $5HT_2$ binding sites increases significantly with no change in affinity.

Age

Our group examined the relationship between age and 5HT, 5HIAA, homovanillic acid (HVA) in the cortex, and caudate and found no effect (Stanley, McIntyre, & Gershon, 1983). An additional study (Severson et al., 1985) examining 5HT and 5HIAA levels in human postmortem samples also noted that age did not appear to influence 5HT or 5HIAA levels or 5HIAA to 5HT ratio. Our group also (Stanley, unpublished) examined the effect of age on imipramine binding in human brain finding a positive correlation between age and the density of imipramine binding sites. This is confirmed by another study showing a positive correlation between advancing age and the density of specific binding sites for imipramine in postmortem samples of human hypothalamus, frontal and parietal cortex (Severson et al., 1985). This is in direct contrast to another study (Langer et al., 1980) indicating that platelet imipramine binding decreases as a function of aging.

The latter finding is of interest since imipramine binding in brain and platelet were thought to be identical. Examination of imipramine binding in cats (Arbilla et al., 1981) that received chronic administration of the tricyclic antidepressant imipramine shows reduction in this binding site in brain and platelets. It is problematic though to argue that drug-induced changes, i.e., down regulation, reflect what is seen in the nondrug state. Our data for imipramine binding in the untreated rat platelet and brain (Stanley, unpublished data) do not indicate a significant correlation between imipramine binding in these two sites. Needless to say, findings such as these raise numerous questions regarding the validity of peripheral measures in general to serve as indices of central systems.

Postmortem Interval

In postmortem research, postmortem interval (PMI) or delay (i.e., that time between death and the time the brain tissue is removed and frozen) may contribute to discrepancies in research results. In our human postmortem studies we have assessed the influences of PMI on 5HT and 5HIAA levels (Stanley, McIntyre, & Gershon, 1983). We found a significant positive correlation between frontal cortex 5HT levels and PMI. No significant findings were noted between 5HIAA or HVA levels and PMI. Additional work by our group in rat brain (McIntyre & Stanley, 1984) indicate a similar influence of PMI on 5HT level, with no change seen in 5HIAA levels. Another study (Severson et al., 1985), however, found a negative correlation between 5HT levels and PMI. One possible explanation for this discrepancy may be the difference in the length of PMI between the two studies. In our study PMI was approximately 15 hours (range: 6 to 45 hours) while in the aforementioned study finding a negative correlation PMI averaged approximately 36 hours (range: 27 to 54.7 hours). It may well be that while 5HT levels appear to rise initially with a shorter PMI they subsequently fall with a more extensive delay.

Previous research has shown that amines such as dopamine (DA) and 5HT are more sensitive to PMI than are their acidic metabolites. Our group looked at the influence of PMI on DA, 3,4-dihydroxyphenylacetic acid (DOPAC), and HVA levels (Wilk & Stanley, 1978; McIntyre & Stanley, 1984). Essentially DA, not DOPAC or HVA levels, is positively correlated with postmortem delay.

Regional Changes

In addition to the above data indicating the influence of age and PMI on measures of serotonergic function, regional or nonspecific brain dissection may also affect results. In an attempt to investigate possible regional differences of 5HT and 5HIAA concentrations within the cortex we dissected homogenous samples corresponding to frontal, temporal, and occipital cortex. In this experiment, the frontal cortex showed significantly higher concentrations of 5HT and 5HIAA compared to temporal or occipital samples. In a second experiment three progressive 1 mm slices of the frontal cortex were examined in a rostral to caudal fashion for regional concentration differences of 5HT and 5HIAA levels (McIntyre & Stanley, 1984). Additional variation was noted within the frontal cortex with a rostral to caudal increase in 5HIAA levels; 5HT levels were consistent. Therefore, differences are found not only among the general areas of cortex, i.e., frontal, temporal, and occipital, but differences are found within each area.

Summary

The above data indicate a strong correlation between various measures in the serotonergic system and suicidal behavior in postmortem studies. This is made evident by the data presented on 5HT and 5HIAA levels, imipramine binding studies, and $5HT_2$ receptor binding studies. From research of this nature it becomes evident that variables such as age, postmortem interval, and regional brain area dissection may have a role in the inconsistencies of data in postmortem evaluations.

Aminergic Receptor Binding Correlates of Suicide: Methodological Issues

J. John Mann, M.D.,[1,2] P. Anne McBride, M.D.,[1] and Michael Stanley, Ph.D.[3]

Animal studies of monoamine receptor binding in the central nervous system (CNS) have generated important hypotheses regarding the mechanism of therapeutic action of somatic antidepressant treatments (Sulser et al., 1978) and antipsychotic agents (Creese et al., 1976). Our laboratory and others have demonstrated the feasibility of assaying monoamine receptors in human postmortem brain tissue (Maggi et al., 1979: Stanley & Mann, 1983). Such studies have yielded important findings in schizophrenia (Snyder et al., 1974), Parkinson's disease, and suicide (Stanley & Mann, 1983). Most of these studies controlled to varying degrees for factors such as age, gender, antemortem drug effects, postmortem delay, and method of death. However, little information exists regarding the relative importance of these variables. This paper will address the impact of these factors upon monoamine receptor binding in postmortem human brain tissue and their specific relevance for findings in suicide research.

Methods

Samples were collected from 35 control subjects and 20 suicide victims with a postmortem delay to autopsy of less than 24 hours. All brains underwent macroscopic and microscopic examination to exclude neuropathology. Clinical history, autopsy findings, and toxicology were used to exclude alcoholism and drug abuse. All samples were stored at −70°C until assay. Details of tissue handling have been described elsewhere (Mann et al., 1986).

Beta-adrenergic receptors were assayed using 45 pM (^{125}I) iodopindolol and 10 μM (−)-propranolol to define specific binding. Serotonin-1 (5-HT$_1$) receptors were assayed using the ligand ^{3}H-serotonin (4 nM) and 10 μM serotonin to define specific binding. Serotonin-2 (5-HT$_2$) receptors were assayed with 0.2 nM H-spiroperidol and 1 μM ketanserin. Dopamine-2 (D2) receptors were assayed with 0.2 nM ^{3}H-spiroperidol and 1 μM (+)-butaclamol. These methods have been previously described (Mann et al., 1986). All ligands were purchased from New England Nuclear, Massachusetts. Complete saturation binding isotherms for 5-HT$_1$ and 5-HT$_2$ receptors were carried out on a limited number of samples. Binding was quantified in terms of protein content (Lowry et al., 1951) and calculated using a Scatchard transformation.

Results

1. *Effects of Postmortem Delay.* The only significant effect of postmortem delay on the monoamine receptor binding indices measured was a decline in cortical β-adrenergic binding that correlated with the time delay before refrigeration at 4°C. This effect was accounted for by samples with a >4 hour delay to storage at 4°C. For other receptors no significant correlations were found between binding and overall time to autopsy (5-HT$_1$, $r = -0.2$; 5-HT$_2$, $r = -0.2$; D$_2$, $r = -0.12$).

2. *Effects of Age.* A significant age-related decline was observed in 5-HT$_2$ binding in frontal cortex ($r = -0.42$, $p < 0.01$, $n = 34$). This was due to fewer binding sites (B_{max}) and occurred in the absence of a change in K_D. In contrast no statistically significant age-related changes were observed in 5-HT$_1$, β-adrenergic, or D$_2$ binding. However it should be noted that the age range of the samples assayed for β-adrenergic and D$_2$ binding included too few samples from younger sub-

jects (mean ages 61.7 and 64.9 years, respectively) and therefore an age effect could not be excluded with certainty. In fact, when separated on the basis of median split for age, older subjects had 40 percent less β-adrenergic binding than younger subjects (3.1 ± 0.9 versus 4.9 ± 1.1 fmol/mg, respectively).

3. *Effect of Gender*. Gender did not appear to affect any of the monoamine receptor binding indices. Furthermore, although the number of samples from premenopausal women was small, no suggestion was found for an effect due to menopause.

4. *Method of Death: The Effects of Violence and Hypoxia*. In the control subjects no effect of violent versus nonviolent cause of death was found upon either 5-HT$_2$ or β-adrenergic binding (99.9 ± 18.4 versus 103.7 ± 16.3; 10.1 ± 2.7 versus 8.9 ± 2.5, fmol/mg, respectively). Similar data were not available for the suicide victims since the protocol required the exclusion of subjects dying from drug overdose and therefore the bulk of the remainder used violent means for suicide.

The effects of hypoxia were assessed by comparing suicide victims who died by asphyxiation to those who died by other methods. No significant differences were found in 5-HT$_1$, 5-HT$_2$, and β-adrenergic binding. D$_2$ binding was not determined in suicide victims.

Discussion

The apparent selective susceptibility of β-adrenergic binding to delays of >4 hours prior to refrigeration at 4°C indicates the importance of distinguishing between overall time to autopsy and time to storage at 4°C. Autopsies on suicide victims are usually carried out by medical examiners or their equivalent, and there is usually a longer delay to refrigeration at 4°C than with hospital cases where the autopsy is carried out inhouse. Since we and others have demonstrated changes in β-adrenergic binding in suicide victims, it is clearly of importance to use appropriately matched controls, preferably collected from the same source.

We found a 50 percent decline in the number of 5-HT$_2$ binding sites in frontal cortex between the ages of 15 and 70 years. A similar age-related decline in β-adrenergic sites could not be excluded on the basis of our preliminary data. The same receptor sites were found to be upregulated in suicide victims relative to matched controls. Clearly matching for age is essential in studying these systems in suicide victims.

Paradoxically, there is an age-related decline in most measures of noradrenergic indices including norepinephrine cell bodies in the locus coreleus, norepinephrine, MHPG, tyrosine hydroxylase, and dopa decarboxylase. A compensatory upregulation of postsynaptic β-adrenergic receptors may be hypothesized on the basis of this evidence of a decline in presynaptic noradrenergic activity. However, our findings indicate that this does not occur. Animal studies are even clearer and indicate an age-related decline in β-adrenergic binding. Therefore, apart from an age effect upon presynaptic noradrenergic function, there appears to be an additional effect upon the postsynaptic receptors.

In the serotonergic system the consequences of aging appear to differ significantly from what is observed in the noradrenergic system. Levels of 5-HT, 5-HIAA, and in animal studies tryptophan hydroxylase do not alter significantly with aging. In the absence of an alteration in presynaptic serotonergic indices, the finding of a loss in postsynaptic 5-HT$_2$ binding sites suggests a direct aging effect on the as yet unidentified cortical neuron on which the 5-HT$_2$ receptor is located.

As mentioned previously in contrast to 5-HT$_2$ receptors we found no age effect on 5-HT$_1$ receptors. However, considerable evidence exists to indicate that 5-HT$_1$ and 5-HT$_2$ receptor populations are independently regulated and have a different regional distribution in the brain. Therefore, the relative sparing of the 5-HT$_1$ receptors in normal aging may be another example of this independent regulation. Also consistent with this dissociation is our finding that, although 5-HT$_2$ receptors are upregulated in suicide victims, 5-HT$_1$ binding indices are unaltered.

Several laboratories have reported an age-related decline in nigrostriatal dopaminergic neurons and a fall in dopamine levels (Carlsson et al., 1980). Such an apparent reduction in dopaminergic function does not result in a detectable increase in D$_2$ binding, and it is possible that aging may impair this homeostatic adjustment. Animal studies actually report an age-related loss of D_2 binding sites. The direction of change is therefore indicative of a postsynaptic aging effect on these receptors.

Gender is an important factor in determining the prevalence of affective disorders (2 to 3 times greater in females) and suicide (2 to 3 times more common in men). In normal controls with no known psychiatric history no gender differences were seen in monoamine receptor binding. This finding is consistent with the absence of gender differences in levels of norepinephrine, 5-HT, 5-HIAA, and dopamine (Gottfries, 1980). Thus, gender does not appear to affect monoaminergic measures. However, it should be noted that most studies assayed tissue from the frontal lobe where there are relatively few estrogen receptors and therefore important gender-related differences in monoamine may have been missed.

Other factors such as violence or suddenness of death or a hypoxic death did not appear to affect binding indices. While this study tended to exclude samples from subjects with confounding antemortem drug use, it should be noted that psychotropic drugs can affect binding. Antidepressant drugs have been shown in animal studies to reduce the B_{max} of 5-HT_2 and/or β-adrenergic binding sites after chronic administration. Antipsychotics are competitive inhibitors of D_2 and 5-HT_2 sites and would therefore alter K_D. Since these classes of compounds are frequently used in depression and schizophrenia and their effects on β-adrenergic and 5-HT_2 binding are in the opposite direction to that found in suicide victims and perhaps depression, it is critical to exclude subjects where antemortem use of these drugs can be established.

An important area for future work involves the study of regional differences using techniques such as quantitative autoradiography and immunocytochemistry. Regional studies will yield information about the distribution of effects and will assist in the distinguishing presynaptic system effects from localized regional effects. Confident interpretations of the significance of disease-related findings can only be made against a background of such normative data.

Neuropeptides as Stimulators of Feeding

John E. Morley, M.D.,[1] James E. Mitchell, M.D.,[2] and Allen S. Levine, Ph.D.[3]

The complexities of the ingestive process make it extremely unlikely that any *single* neurotransmitter will be found to regulate this behavior. Over recent years it has become clear that a variety of neurotransmitters can modulate ingestion (Morley & Levine, 1985). For simplicity, the regulation of feeding can be divided into a peripheral satiety system and a central feeding system. This model suggests that the majority of hormones and neurotransmitters released during the passage of food through the gastrointestinal tract are responsible for relaying inhibitory messages to the central nervous system (CNS). Two exceptions to the rule that peripherally released hormones produce satiety are the well-recognized hunger provoking effects of insulin administration and the fact that motilin increases food intake in starved rats (Garthwaite, 1985).

Within the CNS, it appear that the regulation of feeding involves the interaction of a variety of neurotransmitters. Based on neuropharmacological data it has been suggested that these neurotransmitters are arranged in a cascade system similar to the well-recognized cascade systems responsible for the regulation of blood clotting and complement fixation (Morley, 1980). Growing evidence also suggests that there are, in fact, a number of systems arranged in parallel allowing the food selection process to take place.

Within the CNS a number of these neurotransmitters appear to be primarily stimulators of feeding (Table 1). The classical CNS stimulator of feeding is the monoamine, norepinephrine, which appears to exert its effect predominantly within the paraventricular nucleus (Leibowitz, 1980). Dopamine can also stimulate feeding at low concentrations; while at higher concentrations, the development of dopamine-induced stereotypy inhibits feeding (Morley et al., 1982). The amino acid neurotransmitter, gamma amino butyric acid, and its analog, muscimol, will stimulate feeding when applied to the medial hypothalamus while inhibiting feeding in the area of the lateral hypothalamus (Morley et al., 1981). Recently, Kyrkouli et al. (1985) have shown that the 29 amino acid peptide, galanin, which co-exists with norepinephrine in the paraventricular nucleus, will stimulate feeding. Growth hormone-releasing hormone has been shown to stimulate feeding at low concentrations while inhibiting it at

        - Peptide Y
    Galanin
    Growth Hormone Releasing Hormone

higher concentrations (Vaccarino et al., 1985). Two other families of peptides, the opioid peptides and the pancreatic polypeptide family, have also been demonstrated to be potent stimulators of feeding, and the remainder of this brief review will address the effects of these neurotransmitters.

Opioid Peptides and Feeding

The ability of opioid peptides to stimulate feeding and for the opioid antagonist, naloxone, to inhibit feeding has been comprehensively reviewed recently (Morley et al., 1983). There is now increasing evidence that the kappa opioid receptor is primarily responsible for the ability of opioids to stimulate feeding. In particular, the endogenous kappa ligand, dynorphin, appears to be a potent stimulator of feeding (Morley & Levine, 1981). Although the primary opioid system involved in the stimulation of feeding is the kappa opioid system, there is also evidence for a second non-mu, opioid feeding system (Morley et al., 1985c). It appears that opioids can regulate feeding within at least three separate areas within the CNS, viz. the paraventricular nucleus, the amygdala, and the globus pallidus (Gosnell et al., 1984, 1986; Stanley et al., 1984).

A number of studies have now demonstrated that naloxone will decrease the amount of food eaten over a single meal (Atkinson, 1982; Cohen et al., 1985; Morley & Levine, 1982; Trenchard & Silverstone, 1983). Of particular interest is the fact that naloxone decreased food intake without altering the perception of satiety (Trenchard & Silverstone, 1983). Similarly, we found that while butorphanol tartrate, a mixed opiate agonist/antagonist which preferentially binds to the kappa receptor, could increase food intake in normal subjects over 6 hours, it failed to alter the perception of hunger (Morley et al., 1985a). Using the longer acting analog of naltrexone, nalmafene, we found that food intake could be suppressed for up to 24 hours (Billington et al., 1985). In these studies we found that opioid antagonism predominantly decreased fat intake, which is in keeping with previous studies in rodents (Marks-Kaufmann & Kanarek, 1981). It needs to be pointed out, however, that fat-containing foods tend to be the most palatable; and, thus, the effect of opioid antagonism may be more specifically directed towards palatability rather than fat *per se*.

Unfortunately, it appears that tolerance to the effects of opiate antagonism on food intake develops rapidly. We gave naltrexone (300 mg/day or placebo) for 8 weeks in a double-blind, controlled trial to obese males. We could demonstrate no advantage of naltrexone over placebo as far as weight loss was concerned. In addition, naltrexone produced mild hepatotoxicity in some of the subjects.

The animal literature has suggested that opioids may play a particularly important role in the induction of stress (Morley & Levine, 1980) and 2-deoxy-glucose induced feeding in humans is inhibited by naloxone (Thompson et al., 1983). We, therefore, examined the effect of naloxone on binge-eating episodes in bulimic patients. Our preliminary data show that naloxone infusion attenuates the amount of food consumed during binge-eating episodes. Cholecystokinin was ineffective at altering binge-eating behavior. These results support the hypothesis that the endogenous opioid system is involved in the maintenance of binge-eating behavior in patients with bulimia.

Anorexia occurs commonly in the elderly. Although it is often precipitated by bereavement and, in some cases, is accompanied by depression, in many patients there appears to be no physical or psychological cause for the onset of anorexia. These patients often appear unaware of the dramatic effects of the associated weight loss and repeatedly deny that they wish to die. In some instances, the patients chew food and then spit it out. This syndrome of senile marasmus bears certain similarities to anorexia nervosa. Recent animal studies have shown that opiates are relatively ineffective at stimulating feeding in older rats and mice (Gosnell et al., 1983; Kavaliers & Hirst, 1985). Naloxone also fails to decrease feeding in older rodents. These animal studies suggest that an attenuated opioid feeding system may play a role in the pathogenesis of the anorexia associated with the development of senile marasmus.

We have previously suggested that the original function of opioid peptides was to stimulate food seeking with the analgesic functions of opioids developing as a genetic mutation when the food seeking animal was forced to forage for food, thus coming into contact with danger and pain (Morley & Levine, 1982). Many of the other functions of opioids fit with this general construct. Thus, opioids also enhance immune function, decrease gastric acid secretion, elevate blood glucose, and decrease sexual function and luteinizing hormone secretion (Morley, 1980). Further, when opioid function is reduced by feeding or the administration of naloxone, memory is enhanced, thus allowing the animal to fix in its memory the details of its successful foraging expedition!

Pancreatic Polypeptides and Feeding

The pancreatic polypeptide family consists of pancreatic polypeptide, neuropeptide Y, and peptide YY. The latter two peptides were isolated by Tatemoto and his colleagues (1982) and are characterized by having tyrosine at both ends of the molecule and hence the designation YY and Y (Y being the biochemical nomenclature for tyrosine). Neuropeptide Y (NPY) is widely distributed throughout the central and peripheral nervous systems, whereas peptide YY occurs mainly in peripheral tissues. High concentrations of NPY are found within the paraventricular nucleus, suggesting that it may play a role in feeding.

Clark et al. (1984) demonstrated that both human pancreatic polypeptide and, to a greater extent, NPY increased feeding after injections into the third ventricle of ovariectomized rats. Stanley and Leibowitz (1984) reported a similar potent increase in feeding in intact male rats after direct injection into the paraventricular nucleus. Studies in our laboratory confirmed the potent orexigenic effect of NPY in intact male rats (Levine & Morley, 1984). Not only does NPY increase feeding during the daytime when rats don't normally eat, but it also increases nocturnal feeding and feeding in animals after 24-hour starvation. NPY is inactive after peripheral administration. NPY also causes a major increase in water ingestion and this increase in water ingestion is still present, although diminished, in the absence of food. NPY is a highly specific enhancer of the ingestion of carbohydrate-rich foods, being much more potent than norepinephrine in this regard.

As NPY was shown to coexist with norepinephrine within the CNS, a number of studies have attempted to examine the relationship between norepinephrine and NPY on ingestive behaviors. Neither our group (Levine et al., 1984) nor Stanley and Leibowitz (1985) could block the effects of NPY on feeding with the alpha antagonist, phentolamine. In addition, we could demonstrate no synergistic or additive effects of NPY and norepinephrine on feeding. Table 2 compares the effects of NPY and norepinephrine on feeding based on studies in our laboratory. Perusal of these results clearly suggests that NPY and norepinephrine produce their effects on feeding through different mechanisms.

We compared the potency of NPY to PYY and rat pancreatic polypeptide (Morley et al., 1985). We could find no effect of rat pancreatic polypeptide on food or water intake in male rats. PYY, on the other hand, proved to be significantly more potent than NPY. This is in keeping with the potencies of NPY and PYY in the brain receptor assay and in the biological responses in the rat vas deferens as reported by Chang et al. (1985). Of interest is that in the chicken avian pancreatic polypeptide is a far more potent stimulator of feeding than is NPY (Steinman and Morley, unpublished observations).

Chronic administration of PYY every 6 hours for 48 hours leads to a marked increase

TABLE 2. Comparison of the Effects of Neuropeptide Y (NPY) and Norepinephrine on Feeding

	NPY	Norepinephrine
Food Intake	Increase by 7-10 g after ICV injection	Increase by 2-4 g after ICV injection
Water Intake	Increased	No change or decreased
Nutrient Selection	Carbohydrate	Carbohydrate and fat
Blocked by Phentolamine	No	Yes
Site of Action	Anterior VMH and PVN	PVN
Blocked by Vagotomy	No	Yes
Blocked by Adrenalectomy	No	Yes

in food intake (Morley et al., 1985b). There is no tolerance to the orexigenic effect of PYY. Of particular interest in this study was the profound distension of the gastrointestinal tract observed at the end of the 48 hours. The food intakes and stomach distension of the PYY-injected animals attest to the fact that central factors can override the physiological satiety signals from the periphery. Stanley et al. (1985) have demonstrated that rats given repeated NPY injections for 10 days doubled their daily food intake and increased body weight compared to vehicle-injected animals.

These studies suggest that NPY is among the most potent endogenously occurring orexigenic agents yet to be described. The magnitude of food intake seen following NPY is greater than that observed after central administration of any other neurotransmitter. The fact that NPY also produces a selective increase in carbohydrate suggests to us that consideration should be given to the possibility that NPY plays a role in the pathophysiology of bulimia. Should this prove to be the case, we suggest that the term "bulimin" might be used as a suitable descriptive trivial name for NPY.

Acute Exacerbation of Methamphetamine Psychosis and Lasting Dopaminergic Supersensitivity—A Clinical Survey

Mitsumoto Sato, M.D.[1]

Introduction

Methamphetamine (MAP) psychosis has characteristic psychotic features very similar to those of paranoid schizophrenia. In Japan, the number of persons arrested for offenses against the Amphetamine Control Law has increased steadily for more than a decade (Figure 1). Although it is almost impossible to calculate the exact number of MAP abusers, it is presumed that there are 10 to 15 abusers for each person arrested. Accordingly, the total number of abusers in 1984 was estimated to be between 200,000 and 300,000. Thus, the incidence of both MAP abuse and MAP psychosis has dramatically increased in Japan in the last decade, forming a second peak following the first peak of MAP abuse seen shortly after World War II. This clinical survey was made first to re-evaluate the clinical course of MAP psychosis after abstinence and the relapse of the paranoid psychotic state after MAP re-use. It appears important to distinguish between at least two kinds of psychiatric abnormalities: the abnormality related to the acute but transient psychotomimetic action of MAP, and the abnormality resulting from chronic MAP abuse that persists for a long time after abstinence from MAP. Secondly, the prophylactic effect of neuroleptics on the relapse of the paranoid psychotic state was examined in patients with MAP psychosis.

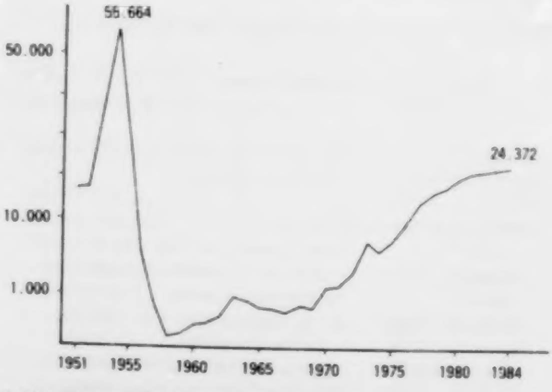

FIGURE 1. Number of persons arrested.

---

[1] Department of Neuropsychiatry, Okayama University Medical School, Okayama 700 Japan

Methods

Two hundred forty-six patients with MAP-use disorders who were admitted to 21 mental hospitals were included in this study. A questionnaire method was applied to 164 patients by team members as a special project of the Japanese Ministry of Welfare (1983–1984). In addition, individual clinical charts of 82 inpatients with MAP psychosis were also examined. The background data of all of the patients are summarized in Table 1.

Most patients used MAP for several years and had a social or occupational impairment due to the pathological pattern of MAP use or the acute pharmacological action of MAP. The drug was self-administered intravenously, and the mean amount of MAP for one injection was estimated by the police to be 30 mg. High-quality MAP in a fine crystal powder form was used. Smuggled MAP produced illicitly in other Asian countries is supplied by Japanese organized crime.

Results

The Mental Symptoms When Admitted to the Mental Hospitals

The symptoms observed in more than half of the 246 patients were: psychomotor excitement, auditory hallucination, delusion of persecution, suspiciousness, anxiety, irritation, emotional lability, and sharpened sensation. Visual hallucination, illusion, delusion of reference, and delusional perception were observed in 25 to 49 percent of the patients. This result is consistent with previous reports by Connell (1958) that the clinical picture of MAP psychosis is primarily a paranoid psychosis with delusion of persecution and hallucination under clear consciousness.

TABLE 1. Background Data of 246 Patients.

Sex	male vs. female = 7.5 : 1
Age when admitted	30's > 20's > under 19 > more than 40
Poly-user	66% (alcohol>glue>hypnotic>other)
Re-admitted case	139 of 246 patients
Methamphetamine (MAP) abuse	
Period	5 to 10 years
Pattern	Inability to reduce or stop use
Route	Intravenous injection
Amount of MAP	30–90 mg/injection, 1 to more than 10 injections/day
Form of MAP	High-quality fine crystal powder
Supply	Smuggled MAP produced illicitly

MAP = methamphetamine

Duration of the Psychotic State After Admission

By treatment with antipsychotics and abstinence from MAP, the active paranoid psychotic state disappeared within 10 days in 64 percent, while it continued for more than 11 days in 36 percent, and for more than 1 month in 18 percent (more than 6 months in 10 percent) of the 82 inpatients. Since the urine MAP test turns negative within 3 to 5 days after abstinence, it is clear that the paranoid psychotic state with hallucination may continue for a long time after excretion of MAP.

Period of MAP Abuse Necessary to Produce an Initial and a Secondary Psychotic Episode (Relapse)

A significantly shorter period of MAP abuse was sufficient to reproduce the psychotic state than to produce the initial episode (Figure 2). Sixty of 101 patients had a relapse after reusing MAP for less than 1 week, while no patient had an initial psychotic episode within 1 week of MAP use. These findings indicate a lasting susceptibility to relapse of the psychotic state after the initial episode.

There was a marked individual variation in the MAP abuse period up to the first admission with the initial psychotic episode. This result is consistent with previous reports (Tatetsu et al., 1956), suggesting a possible role of disposition, such as a pathoplastic factor, in MAP psychosis. In addition, no relation was found statistically between the duration of MAP abuse before the initial episode and that before the relapse. Occurrence of the initial psychotic episode itself, rather than the period of MAP abuse for the initial episode, may indicate the emergence of biological susceptibility to relapse of the psychotic state.

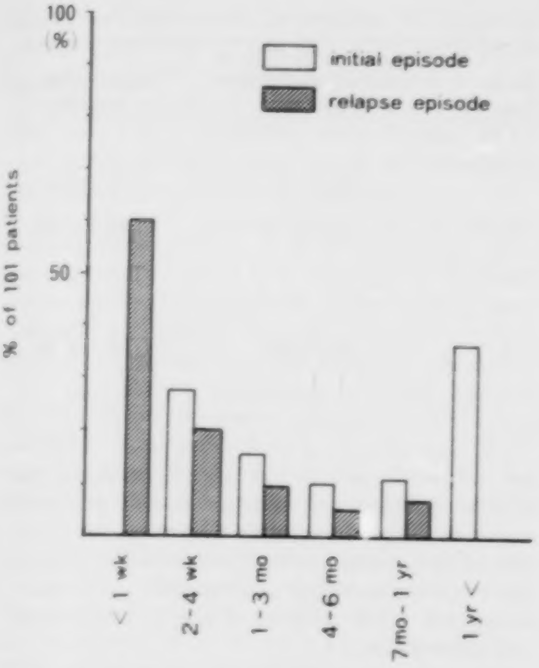

FIGURE 2. Duration of MAP abuse.

Pattern of Acute Exacerbation by MAP Reuse

Twenty-one patients were selected according to four criteria: 1) a history of MAP use of more than 1 month, 2) an experience of MAP-induced psychotic state similar to acute schizophrenia, 3) the reactivation of any psychotic state with re-exposure to MAP with an abstinence interval of more than 1 month, and 4) the availability of reliable information about the status of MAP use given by a third person.

The clinical pictures during the initial psychotic episode and relapses were compared (Table 2). Bizarre delusions included delusions of being controlled, thought insertion, or thought broadcasting. The incidence of each psychotic item in relapses of the psychotic episode did not differ significantly from that in the initial psychotic episode. This result indicates that relapse of the psychotic state is almost identical to the initial psychotic episode.

Patterns of the Relapse. With a long abstinence interval, acute exacerbation of the psychotic state was observed after a single injection in 10 cases and after a few injections in 6 cases (Table 3). A single injection of a smaller amount of MAP than the initial injection was enough to cause recurrence of the psychotic state in 4 patients.

Prophylactic Effects of Antipsychotics on Relapse of MAP Psychosis

There were 8 patients who used MAP again without the knowledge of the doctor, while they were receiving neuroleptics in the outpatient clinic. All of them had an initial psychotic episode in the past, and 3 of them had one or more relapses after using MAP again (Table 4). Two to 3 mg/day of haloperidol prevented the recurrence of any paranoid psychotic state when the patients injected themselves with 30 to 90 mg of MAP once a day or 10 times within a few days. One patient who took 1.5 mg/day of haloperidol and injected himself with 30 to 90 mg several times a day developed a marked suspicious tendency and illusional experience, but he did not develop a paranoid psychotic state resembling the initial psychotic episode. One hundred mg of levomepromazine and trifluperazine also prevented recurrence of the psychotic state, but 30 mg/day of thioridazine was insufficient to prevent the relapse completely.

Discussion

The present study indicates two types of clinical course in MAP psychosis after abstinence. Type A is a psychotic state which begins to improve along with a disappearance of

TABLE 2. Clinical Manifestations of the Acute Phase of 21 MAP Patients.

Symptoms	Episode	
	Initial	Relapse
Bizarre delusion	23.8%	37.5%
Delusions with jealous or persecutory content	100.0	100.0
Hallucinations		
Auditory	76.2	93.8
Visual	38.1	43.8
Incoherence, loosening of association	19.0	18.8

MAP = methamphetamine.

the acute central action of MAP. This type suggests a paranoid psychotic state which is dependent on the MAP-induced hypercatecholaminergic state, probably hyperdopaminergic state. In Type B, the psychotic state continued for more than 11 days in 36 percent and for more than 1 month in 18 percent of the patients, even though MAP is metabolized and excreted rapidly. This suggests a paranoid psychotic state in which the clinical course is independent of a MAP-induced hyperdopaminergic state. Thus, chronic MAP use results in a lasting change in both brain dopaminergic and non-dopaminergic systems that relate to the paranoid psychotic state. The data from this study do not allow us to discuss a difference in the clinical picture of the paranoid psychotic states in Types A and B. However, the content of delusions and hallucination in Type A was realistic and characterized by great suspiciousness, while that in Type B was bizarre and unrealistic.

Since no urine MAP test was performed in most cases, it is hard to exclude the possibility completely that the patients continued to use MAP after admission, although it seems almost impossible. Another possibility is that MAP brought about a worsening of a preexisting schizophrenic state from which the patient was unable to recover. Although there were some reports indicating exacerba-

tion of schizophrenic symptoms by amphetamines (Janowski & Davis, 1976), such exacerbations were transient and cannot explain the clinical course of Type B patients. Type B may indicate a possibility that chronic MAP can result in the same kind of biological changes as those of schizophrenia.

The present study showed that a significantly shorter period of MAP use, even a single injection with a lesser amount of MAP than before, reproduced a psychotic state identical to that in the initial episode after years of abstinence. This result indicates a very long-lasting augmentation and qualitative alteration of the response to MAP presumably established during the chronic MAP abuse. In addition, this study showed that acute exacerbation by reuse of MAP was prevented by a small dose of haloperidol. Since haloperidol has an antipsychotic action by blockade of dopamine$_2$ receptor sites, a lasting dopaminergic hyperreactivity may play an important role in the long-term susceptibility to relapse of the paranoid psychotic state.

The clinical course of MAP psychosis with susceptibility to relapse (Sato et al., 1983) can be reproduced in animal experiments (Figure 3). As in the psychotic state of MAP psychosis in humans, the chronic intermittent administration of MAP produces progressive and enduring changes in animal behavior, a phenomenon known as behavioral sensitization.

In both cases, behavioral abnormalities are easily reproduced when the drug is administered again after a long time of abstinence. Since this behavioral sensitization has been regarded as an animal model of MAP psychosis, there have been many attempts to identify a lasting change in the brain of amphetamine-treated animals. Up to date, several working hypotheses have been proposed from the animal studies to explain the mechanisms for acute exacerbation of the psychotic state. With regard to an excessive brain dopaminergic response to MAP and/or psychological stress, a lasting subsensitivity of presynaptic autoreceptors in the striatum (Antelman & Chiodo, 1981) and nucleus accumbens (Kashihara et al., in press), lasting increase in postsynaptic DA receptors in the nucleus accumbens (Akiyama et al, 1982), lasting enhancement in frontal cortex DA utilization (Robinson et al., 1985), and many other findings have been reported. As to a change outside of the brain DA system, a lasting decrease in TRH receptor sites in the striatum has been reported (Kajita et al., 1985). However, it should be stressed that dopaminergic hyperreactivity may be crucial for relapse of the paranoid psychotic state by MAP reuse and/or stress, rather than maintainance of the induced psychotic state.

FIGURE 3. Chronological pattern of MAP psychosis and its experimental reproduction.

Summary

The present clinical survey of MAP psychosis in Japan showed the following: 1) chronic MAP abuse produced a paranoid psychotic state similar to that of schizophrenia, 2) the paranoid psychotic state continued for more than 1 month in 18 percent, while it disappeared within a week in 64 percent of 82 patients, 3) the psychotic state of the relapse was identical to that of the initial episode, 4) relapse of the psychotic state resulted from a lesser amount of MAP reuse even after a long abstinence, and 5) a small amount of haloperidol prevented the relapse by MAP reuse.

These results indicate that chronic MAP may result in a long-lasting qualitative change in the acute psychotomimetic action of MAP and increase susceptibility to relapse and, in some cases, prolong psychotic features. The well-known DA hypothesis of schizophrenia relates especially to triggering, rather than maintaining, the paranoid delusional state of schizophrenia as well as MAP psychosis.

Reverse Tolerance to the Ambulation-Increasing Effect of Methamphetamine in Mice as an Animal Model of Amphetamine-Psychosis

Sakutaro Tadokoro, M.D., Ph.D.,[1] and
Hisashi Kuribara, Ph.D.[1]

Amphetamine Abuse in Japan

Before World War II, serious drug-abuse problems had been seen rarely in Japan. However, immediately after the end of the war in 1945, the country experienced an amphetamine abuse epidemic. In 1955, it was estimated that approximately 2 million people abused amphetamines (mainly methamphetamine) and that 200,000 people showed mental disorders, namely amphetamine-psychosis (Tatetsu et al., 1956; Snyder, 1974). This first prevalence period was almost completely suppressed in 1958 by legal regulation, and only a few abusers were observed until 1970.

However, beginning 15 years ago (1970), methamphetamine abuse has made a comeback in Japan, and the number of abusers arrested has progressively increased (the second prevalence period). According to an official report of the Japanese Ministry of Welfare and Public Health in 1985, more than 20,000 methamphetamine abusers have been arrested annually since 1980. These data suggest that approximately 400,000 to 500,000 people may abuse methamphetamine in Japan. Simultaneously, various types of criminal cases, including indiscriminant homicide, have been linked to methamphetamine abuse.

Figure 1 shows the trend in the number of methamphetamine abusers arrested annually since the regulation law went into effect in 1951. The first and second prevalence periods of abuse are clearly demonstrated.

Problems of Amphetamine Abuse

The problems of amphetamine abuse divide mainly into two categories. The first is based on the circulation network of the drugs, mainly methamphetamine. In general, the drug is illegally produced and imported through Korean, Taiwanese, and other Southeast Asian routes, and the black-marketing is controlled mainly by gangster groups (Yakuza or Boryoku). Furthermore, all abusers know that even the possession of the drug is completely illegal; therefore, it is extremely difficult to remove the drug from the black market, and dissuade the abusers from self-administration.

The second category is based on its pharmacologic properties. The problems of amphetamine abuse are not based on drug-taking behavior itself, but rather on the psychotoxic effect of the drug, which induces paranoid-hallucinatory schizophrenia-like symptoms (amphetamine-psychosis) (Tatetsu et al., 1956; Snyder, 1974). It has been considered that amphetamine-psychosis is frequently induced by repeated abuse of amphetamines, i.e., showing a reverse tolerance (sensitization or supersensitivity). In contrast, a tolerance to the euphorogenic effect, which is the main reinforcing effect of amphetamine abuse, is easily induced (Yanagita, 1980). This results in an increase in dosage, frequency, and number of abuses, and simultaneously accelerates the development of amphetamine-psychosis. It has been suggested that schizophrenia-like symptoms appear in about half of the people who have abused daily (30 to 100 mg of amphetamines) for 2 to 3 months (Tatetsu et al., 1956). Moreover, the reverse tolerance to the psychotoxic effect, once produced, persists for a long period, and frequently causes an acute exacerbation of the schizophrenia-like symptoms (Sato et al., 1983).

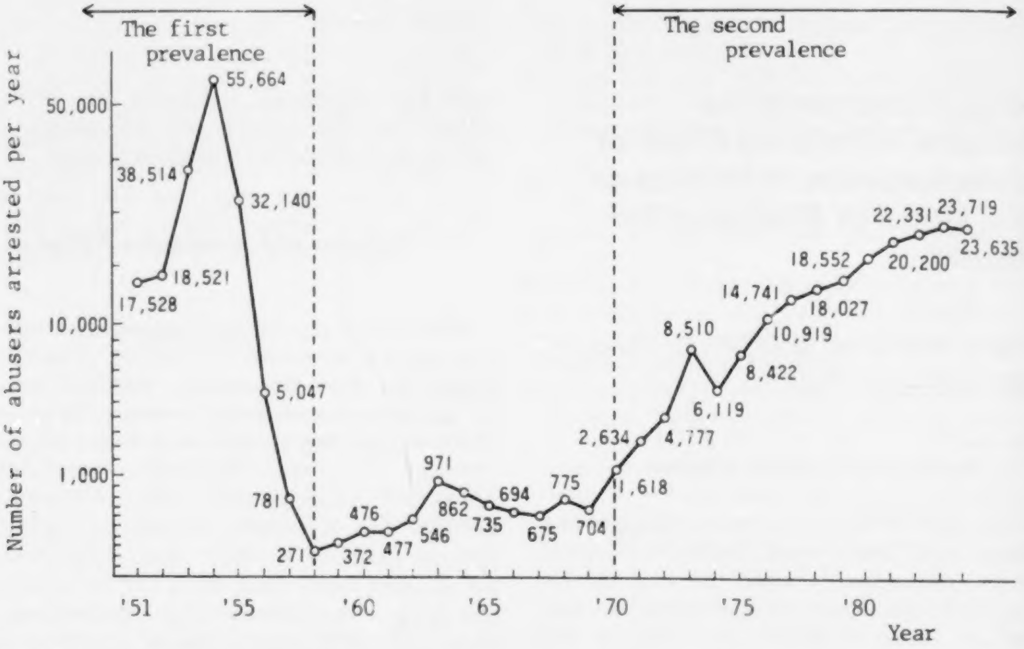

FIGURE 1. Trend of amphetamine abusers arrested annually in Japan since 1951.

In these clinical respects, it is important to study the behavioral effects of amphetamines not only after single but also after repeated administration, in particular concerning reverse tolerance phenomena.

Reverse Tolerance to Amphetamines in Animals

When amphetamines are administered to mice and/or rats, they show a hyperactivity (marked increase in compulsive ambulation or locomotion), and stereotypy such as sniffing, licking, gnawing, backward locomotion, pivotting, etc., depending on the doses administered. Since such behavioral effects of amphetamines have been considered to be intimately related with psychotoxic effects of these drugs in humans, reverse tolerance phenomena to the behavioral effects have been extensively investigated in animals (cf. Kilbey and Sannerud, 1985). In particular, study of the stereotypy-producing effect of comparatively higher doses of amphetamines has been carried out. Although it is difficult to estimate the doses abused in human cases, the usual amount of methamphetamine abused in Japan is considered to be less than 1 mg/kg according to the official report of the Japanese Ministry of Welfare and Public Health. Therefore, the authors have mainly studied the reverse tolerance phenomena to the ambulation-increasing effect of relatively smaller doses of amphetamines in mice. This is because the ambulatory activity and stereotypy shift depending on the doses (Tadokoro, 1985). Furthermore, the ambulatory activity can be measured quantitatively, automatically, and continuously.

Figure 2 shows temporal changes in the ambulatory activity counts after administration of 1 to 16 mg/kg s.c. of methamphetamine in drug-naive mice (Hirabayashi and Alam, 1981). The ambulatory activity of mice was individually measured by a tilting-type ambulometer (Model AM-10; O'Hara & Co. Ltd., Tokyo) which had been assembled originally in the authors' laboratory (Hirabayashi et al., 1978).

Low doses of methamphetamine (1 to 4 mg/kg) increase the ambulatory activity in a dose-dependent manner, whereas no marked stereotypy is observed at these doses. The

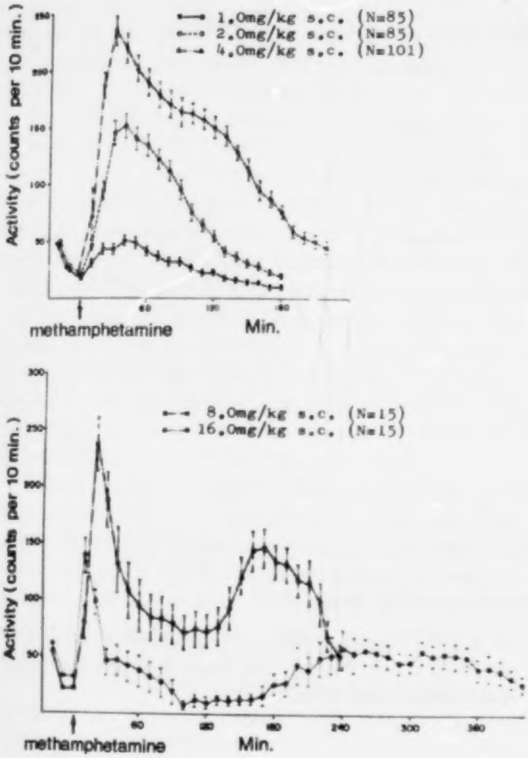

FIGURE 2. Temporal changes in the mean ambulatory activity counts after administration of methamphetamine (1, 2, 4, 8, and 16 mg/kg s.c.) in drug naive mice.

ambulation-increasing effect of methamphetamine attains a peak at 40 to 60 min and persists for 2 to 4 hr after the administration as shown in the upper panel of Figure 2. The behavioral effect of methamphetamine is somewhat stronger than that of *d*-amphetamine. When 8 and 16 mg/kg of methamphetamine are administered, the mice frequently show stereotypy, and the rate of occurrence and the grade of the stereotypy increase in a dose-dependent manner. Since the stereotypy strongly modifies the ambulatory activity, the temporal change in the activity shows irregular patterns at high dosage as demonstrated in the lower panel of Figure 2. Therefore, doses of less than 4 mg/kg have to be used to study reverse tolerance phenomena to the ambulation-increasing effect of methamphetamine in mice.

Figure 3 shows dose-response relations after repeated administration (10 times) of methamphetamine (1, 2 and 4 mg/kg s.c.) at intervals of 1, 3 to 4, and 7 days (Kuribara and Hirabayashi, 1985). The mean overall ambulatory activity counts during a 3 hr observation period in the 1st, 3rd, 5th, 7th, and 10th administration are presented. The ambulatory activity counts progressively increase according to the repetition of the drug administration, showing a development of reverse tolerance to methamphetamine.

Since such reverse tolerance to methamphetamine in animals is similar to enhancement of psychotoxicity of the drug in humans, it is expected that it will be possible to find the basic mechanism of the reverse tolerance to the psychotoxic effect as well as its clinical therapy from the animal studies. The following sections present characteristics of the reverse tolerance to the ambulation-increasing effect of methamphetamine in mice obtained in the authors' laboratory.

1) Doses and Administration Intervals

As demonstrated in Figure 3, there is an optimum dose necessary to observe a clear reverse tolerance to the ambulation-increasing effect of methamphetamine. Two mg/kg s.c. is considered to be optimum in mice.

Administration intervals strongly affect development of the reverse tolerance. For example, repeated administration of *d*-amphetamine at short intervals (e.g., 3-hr intervals) rarely produces a clear reverse tolerance to the ambulation-increasing effect, but rather a tolerance to the effect (characterized by a decline in the duration of the drug effect) is sometimes observed during repeated administration (Tadokoro, 1978). This type of tolerance may be due to an increase in a urinary excretion of the drug resulting from acidification of the urinary pH level which is induced by anorexia (Schuster, 1978). However, a reverse tolerance to *d*-amphetamine is produced in these mice when the drug is readministered 24 hr (or later) after the repeated administration (Tadokoro, 1978).

When the optimum dose of methamphetamine is repeatedly administered at intervals of longer than 1 day, reverse tolerance is induced. However, as demonstrated in Figure 3, the ambulatory activity count attains a ceiling level within several administrations when

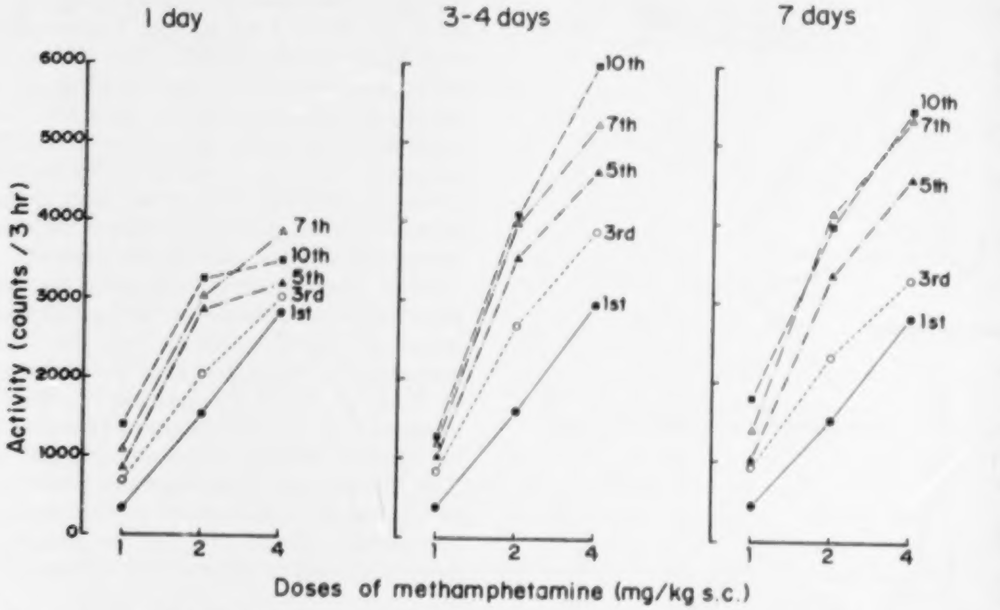

FIGURE 3. Changes in the dose-response curves for the ambulation-increasing effect of methamphetamine (1, 2, and 4 mg/kg s.c.) administered 10 times to mice at intervals of 1, 3 to 4, and 7 days. The mean overall ambulatory activity counts of 30 to 40 mice in the 1st, 3rd, 5th, and 10th administration are plotted.

the repetition is carried out at intervals of 1 day. In contrast, the counts progressively increase throughout the repetition of 10 administrations when the drug administration is done at intervals of 3 to 4 and 7 days. Of course, the activity counts finally attained are higher in the cases of 3 to 4 and 7 days repetition than in the daily repetition.

2) Irreversibility

The reverse tolerance to the ambulation-increasing effect of methamphetamine once produced is maintained for more than 2 months (Hirabayashi and Alam, 1981). The result may be related to the clinical observation that the schizophrenia-like symptoms are easily exacerbated by a readministration of methamphetamine even after withdrawal from drug abuse for several years (Sato et al., 1983).

On the other hand, the development of the reverse tolerance to the ambulation-increasing effect of *d*-amphetamine or methamphetamine is inhibited by a combined administration of antipsychotic drugs such as chlorpromazine or haloperidol in a dose-dependent manner (Tadokoro, 1978; Kuribara and Hirabayashi, 1985). However, the reverse tolerance once produced is not affected by antipsychotic drugs when they are administered repeatedly thereafter (Kuribara et al., 1986).

3) Environmental Effects

The development of reverse tolerance to the ambulation-increasing effect of methamphetamine is strongly affected by environmental situations to which the mice have been exposed during the acute drug exposure. Mice pretreated with repeated administration of methamphetamine in a glass jar (less than 9 cm in diameter), in which the ambulatory movement but not vertical movement is perfectly obstructed, for 3 hr after each drug administration, do not show the reverse tolerance to the ambulation-increasing effect (Hirabayashi and Alam, 1981). In order to produce a clear reverse tolerance, mice have to be exposed to an experimental situation that allows free movement, a diameter of more than 16 cm, which corresponds to 3 times the body length of the mouse (Kuribara and Hirabayashi, 1985).

Furthermore, when a flickering light is presented to the mice during the presence of acute drug effect as a conditioned stimulus, the reverse tolerance tends to be accelerated as compared with that observed in the mice without the flickering light (Hayashi et al., 1980). In addition, the mice that exhibited the reverse tolerance to *d*-amphetamine frequently show an increase in the ambulatory activity when physiological saline is administered, even though the increase persists only for a short time (less than 10 min) (Hayashi et al., 1980).

These results suggest that conditioning of the drug effect is involved in the development of reverse tolerance to the ambulation-increasing effect of amphetamines as emphasized by Kilbey and Sannerud (1985). It is highly probable that such a conditioning mechanism is also involved in the development of amphetamine-psychosis as well as an acute exacerbation and/or the flashback phenomenon in humans.

4) Circadian Variation

There is circadian variation in the sensitivity of mice to the ambulation-increasing effect of methamphetamine; the highest and lowest sensitivities are observed during the late dark and late light periods, respectively (Kuribara and Tadokoro, 1982). The reverse tolerance to methamphetamine is induced almost independently of time of day of repeated administration, and the circadian variation in the drug sensitivity is still maintained (Kuribara and Tadokoro, 1984a).

5) Strain Differences

Sensitivity to the ambulation-increasing effect of methamphetamine differs among strains of mice. The dd, ICR, DBA/2, and C3H/He strains show a comparatively higher sensitivity, and they exhibit a clear reverse tolerance after repeated administration of the drug. Although the BALB/c and C57BL/6 strains show a lower sensitivity to methamphetamine, they also exhibit the reverse tolerance (Kuribara and Hirabayashi, 1985). Recent investigation in the authors' laboratory indicates marked differences in the catecholamine receptor binding sites in the brain (e.g., striatum and cortex) among these strains (Hayashi et al., unpublished data).

The strain differences might be important in relation to individual differences in drug sensitivity in humans. However, the present results also suggest that amphetamine-psychosis is induced in all abusers.

6) Cross Reverse Tolerance

Other drugs such as cocaine, methylphenidate, ephedrine, apomorphine, L-dopa, bromocriptine, morphine, etc., increase ambulatory activity in mice. Repeated administration of these drugs produces a reverse tolerance to the ambulation-increasing effect when optimum doses are administered (Kuribara and Hirabayashi, 1985). The mice that exhibited reverse tolerance to these drugs sometimes show an increase in sensitivity to amphetamines, and vice versa, showing a cross reverse tolerance (Kuribara and Hirabayashi, 1985).

In addition, although repeated treatment with scopolamine and toluene induces tolerance to their ambulation-increasing effect, the mice exposed to these drugs demonstrate an increase in the sensitivity to methamphetamine (Kuribara and Tadokoro, 1984b, 1984c).

These results suggest the possibility that amphetamine abusers use such drugs as substitutes for amphetamines, and vice versa, and that amphetamine-psychosis may be induced and/or exacerbated by these drugs.

7) Neurochemical Changes

It has been reported that repeated administration of high doses of amphetamines decreases monoamine and their metabolite contents and causes changes in presynaptic dopamine autoreceptor binding sites in the brain for a long period even after withdrawal (cf. Kilbey and Sannerud, 1985). However, the neurochemical changes are considered to be insufficient to explain the process of reverse tolerance to the ambulation-increasing effect at low amphetamine dosage. Study of the correlation between amphetamine-induced neurochemical changes and reverse tolerance in the same experimental situation on the same animals could clarify these observations.

Conclusion

In this paper. the authors demonstrated the reverse tolerance phenomenon to ambulation-increasing effect of amphetamines in mice using behavioral pharmacologic models. The main characteristics are: 1) an enhancement of the behavioral effect, 2) long persistence, and 3) easy reproducibility by readministration. It is considered that these characteristics are quite similar to the development of amphetamines-induced psychotoxicity during repeated abuse of the drugs in humans. Since the ambulatory activity of mice can be measured quantitatively and continuously with an automatic apparatus, reverse tolerance to the ambulation-increasing effect of amphetamines in mice is a useful tool to study amphetamine-psychosis.

Psychotic Manifestations in Amphetamine Abuse—Experimental Study on the Mechanism of Psychotic Recurrence

Kiyoshi Ando, Ph.D.,[1] Naoyuki Hironaka, M.A.,[1] and Tomoji Yanagita, M.D., Ph.D.[1]

Amphetamine psychosis is usually developed with repeated administration of amphetamines at high doses. Following termination of the amphetamine administration, recurrence of the psychotic symptoms may be observed after a single dose of amphetamine, after taking some other drug such as alcohol, or seemingly triggered by some other undetermined event.

The mechanisms involved in such recurrence, flashback, or supersensitivity to amphetamine in humans are not well understood. On the other hand, there exists considerable evidence that repeated administration of amphetamine to rats and mice also produces increased sensitivity to amphetamine (Hayashi, Ohashi, & Tadokoro, 1980; Segal & Mandell, 1974). It was also reported that increased sensitivity to amphetamines as observed in rat motor activity, may be attributable to respondent, or Pavlovian conditioning of the activity to the environmental stimuli associated with the amphetamine-injection procedure (Beninger & Hahn, 1983; Pickens & Crowder, 1967; Tilson & Rech, 1973). However, no studies so far seem to have addressed the question of conditioning of amphetamine effects by non-amphetamine drugs using a respondent conditioning paradigm in laboratory animals.

The purpose of our study was to examine whether the behavioral effects of amphetamines were conditioned by other drugs in laboratory animals and whether the data obtained by the animals give the basis for understanding the mechanisms of psychotic manifestations in amphetamine abuse.

Method

Experiment 1. Conditioning of the effects of *d*-amphetamine on spontaneous motor activity by other drugs in mice.

Spontaneous motor activity of male ICR mice was measured by an activity count system (Automex, Columbus Instruments, Ohio). Upon receiving the mice, they were randomly divided into three groups of eight mice per group according to the drugs paired with *d*-amphetamine at 2 mg/kg, administered subcutaneously (s.c.), in the conditioning sessions. Before the conditioning sessions were started, the spontaneous motor activity of the mice of each group was observed for 1 h before and for 2 h after administration of saline 10 ml/kg, s.c. Three or four days after the saline administration test, the drug to be paired with *d*-amphetamine at 2 mg/kg, s.c., was tested by the subcutaneous route in the same manner as in the saline administration test. The drugs to be paired with *d*-amphetamine at 2 mg/kg, s.c., were pentobarbital 8 mg/kg for pentobarbital group, caffeine 6 mg/kg for caffeine group, and *d*-amphetamine 0.25 mg/kg (to be distinguished from the main dose at 2 mg/kg) for *d*-amphetamine group each administered subcutaneously. After the above tests, conditioning sessions were started. In conditioning sessions, activity counts were measured in the same manner as before; however, depending on the group, either pentobarbital, caffeine, or the *d*-amphetamine at above described doses was administered by the subcutaneous route. Five min after the administration of one of the paired drugs, *d*-amphetamine 2 mg/kg, s.c., was administered, and immediately after this administration, the activity counts were measured for 2 h. This kind of conditioning session was given two times per week, with contiguous sessions separated by 3 to 4 days. After nine conditioning sessions, test sessions were given in the same manner except that either saline at 10 ml/kg, s.c., pentobarbital at 8 mg/kg, caffeine 6 mg/kg, or *d*-amphetamine at 0.25 mg/kg was administered regardless of group, and 5 min after the administration, saline 10 ml/kg, s.c., was administered instead of *d*-amphetamine 2 mg/kg, s.c. Each test session was repeatedly given between conditioning sessions with at least one conditioning session before each test session. Relative activity counts were obtained as the percent ratio of activity counts during 1 h after administrations against the values for 1 h before administrations.

[1] Preclinical Research Laboratories, Central Institute for Experimental Animals, 1433, Nogawa, Miyamaeku, Kawasaki 213 Japan.

Experiment 2. Conditioning of the effects of methamphetamine on schedule controlled behavior by imipramine and external stimuli in rats.

Male Sprague-Dawley rats were used. Daily food was limited to 18 g per rat and water was freely available in home cages and during experimental sessions in operant chambers.

Responding was established under a differential reinforcement of low rate (DRL) 20-sec schedule where each lever press response that was followed by no less than 20 sec of nonresponding timed at least 20 sec was reinforced with a food pellet (50 mg). After establishment of responding under this schedule, rats were divided in two groups, an experimental and a control group. In the experimental group ($N = 5$), conditioning sessions and baseline sessions were given. In the conditioning sessions, imipramine 2 mg/kg, s.c., was administered after observation of responding under this schedule for 1 h. Methamphetamine 0.5 mg/kg, s.c., was administered 5 min after the imipramine administration, and then responding under the DRL schedule was observed for 1 h. During the 1-h sessions, synchronized presentations of interrupted buzzer sounds and lights (0.5 sec on and 1 sec off) were made in the operant chamber. The buzzer sounds and lights (external stimuli) were given during 1-min periods separated by 1-min time-out intervals of the presentation of the external stimuli. Such conditioning sessions were given twice a week for several weeks. In baseline sessions which were given three times a week on nonconditioning session days during the same period, responding under the DRL schedule was maintained and observed for 2 h without any administration or presentation of the external stimuli. After nine conditioning sessions, conditioning sessions and baseline sessions were given in the same manner, but test sessions were given on one of the conditioning session days of each week. Test sessions were conducted in the same manner as the conditioning sessions except that methamphetamine was not administered and one of the components, i.e., imipramine administration or the external stimuli, was removed or changed. In the control group ($N = 6$), the baseline sessions and control sessions were given in the same manner as in the experimental group. The control sessions were the same as the conditioning sessions except that saline 1 ml/kg, s.c., was administered instead of methamphetamine 0.5 mg/kg, s.c. The test sessions in the control group were given in the same manner as in the experimental group.

The data were number of responses during post-administration 30 min or comparable period in the baseline sessions.

Results

Experiment 1. Conditioning of the effects of *d*-amphetamine on spontaneous motor activity by other drugs in mice.

Figure 1 shows the change in mean percent activity counts before, during, and after conditioning sessions in the caffeine group.

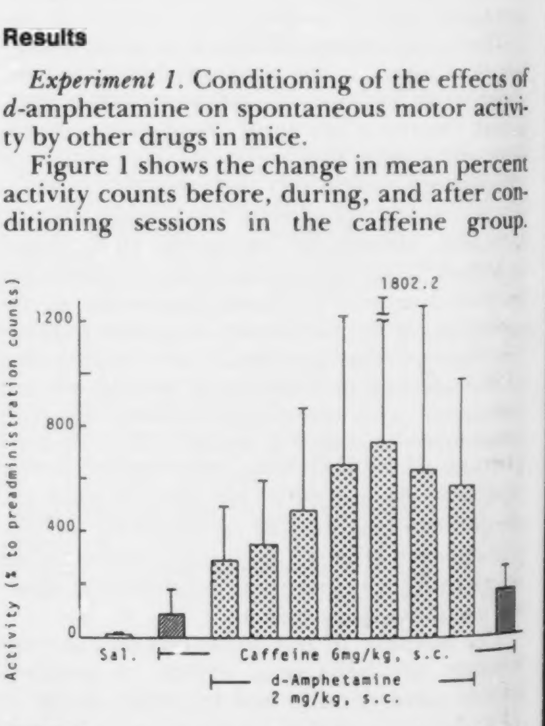

FIGURE 1. Mean percent activity counts with standard deviation for 1 h after administrations before, during, and after conditioning sessions in caffeine group mice ($N = 8$).

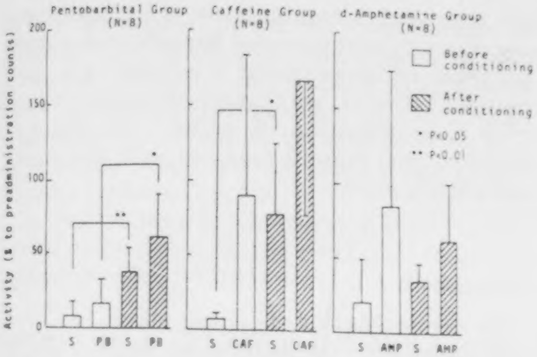

FIGURE 2. Mean percent activity counts with standard deviation in mice 1 h after administrations in tests before and after conditioning sessions in each group. S: Saline 10 ml/kg, s.c. PB: Pentobarbital 8 mg/kg, s.c. CAF: Caffeine 6 mg/kg, s.c. AMP: *d*-Amphetamine 0.25 mg/kg, s.c.

Before conditioning, the counts with saline were relatively low and the counts with caffeine 6 mg/kg, s.c., were higher than with saline. The counts increased with caffeine 6 mg/kg, s.c., and *d*-amphetamine 2 mg/kg, s.c., during conditioning. In a test with caffeine 6 mg/kg, s.c., without *d*-amphetamine after conditioning, the counts were higher than those with caffeine before conditioning. In the other two groups, the changes in counts were basically similar to those of the caffeine group; that is, the counts were highest in conditioning sessions and lowest in sessions with saline before conditioning.

Figure 2 shows the mean percent activity counts before and after conditioning sessions for each group. In the pentobarbital group, the activity counts with saline and with pentobarbital at 8 mg/kg in the tests after conditioning were significantly higher than those before the conditioning. In the caffeine group, caffeine 6 mg/kg, s.c., alone increased activity counts before conditioning. After conditioning, the counts with saline and with caffeine were higher than before conditioning. The increase with caffeine after conditioning was not significantly different from the counts with caffeine before conditioning, because of high variability in the counts with caffeine. In the *d*-amphetamine group, *d*-amphetamine at 0.25 mg/kg, s.c., alone increased activity counts but the counts with *d*-amphetamine at that dose after conditioning were not higher than before conditioning.

In other tests given after conditioning, each group received not only the designated paired drug but also the paired drugs used in the other groups. As shown in Table 1, the activity counts were highest with caffeine at 6 mg/kg, s.c., in the caffeine group as well as in the other groups after conditioning. Thus, the counts were not highest with the designated paired drug in the pentobarbital and *d*-amphetamine groups.

Experiment 2. Conditioning of the effects of methamphetamine on schedule controlled behavior by imipramine and external stimuli in rats.

Figure 3 shows the changes in the number of responses for 30 min after administrations in the experimental group. Imipramine 2 mg/kg, s.c., did not significantly increase the numbers of responses with the external stimuli in comparison with the numbers in the baseline sessions before conditioning. The number of responses increased with the addition of methamphetamine 0.5 mg/kg, s.c. After nine conditioning sessions, the number of responses in a test session with imipramine 2 mg/kg, s.c., and with the external stimuli but without methamphetamine were significantly higher than the number in the baseline ses-

TABLE 1. Mean Percent Activity Counts of Mice With Standard Deviation in Tests With Cross Drugs Given After Conditioning Sessions.

Group	Test Drug			
	SAL 10 ml/kg	CAF 6 mg/kg	PB 8 mg/kg	AMP 0.25 mg/kg
CAF	77.5 + 47.5	166.3 + 89.4	64.2 + 60.8	104.2 + 79.5
PB	37.3 + 16.6	125.2 + 67.7**	61.0 + 29.7*	75.3 + 37.3
AMP	34.5 + 21.4	137.0 + 61.7**	56.3 + 18.5*	61.7 + 37.6

SAL: Saline, CAF: Caffeine, PB: Pentobarbital, AMP: *d*-Amphetamine
*: $p < 0.05$ vs. saline, **: $p < 0.01$ vs. saline.

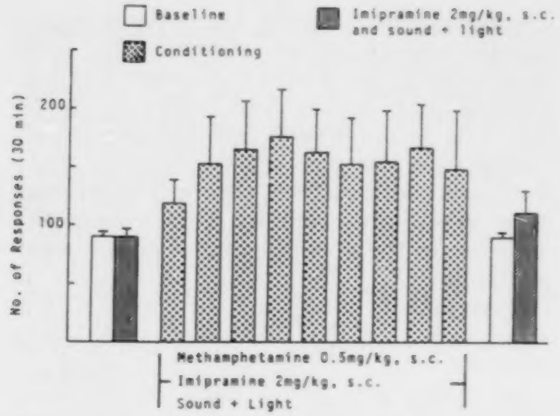

FIGURE 3. Mean number of responses with standard deviation for 30 min before, during, and after conditioning sessions in the experimental group. The mean number of responses in the baseline sessions given between each pair of conditioning sessions is not shown in this figure.

sion immediately prior to the test session and the number in a session with imipramine and the external stimuli before conditioning. In the control group, no changes in the numbers of responses compared with the baseline sessions were observed, and the numbers in the control sessions and baseline session were stable throughout the experiment.

The results of the tests given after conditioning are shown in Table 2. The number of responses were compared between the control and experimental groups and were statistically tested in various tests. The mean number of responses in the experimental group was higher than that in the control group in the tests with a combination of imipramine 2 mg/kg, s.c., and external stimuli, with a combination of imipramine 2 mg/kg, i.p., and external stimuli, with imipramine alone, and with a combination of saline 1 ml/kg, s.c., and external stimuli, but not with the external stimuli alone.

Discussion

In the context of the respondent conditioning paradigm, the effects of amphetamines may be considered as unconditioned stimuli with the other stimuli associated with amphetamine administration serving as conditioned stimuli, if it can be shown that the stimuli alone without amphetamine produce effects similar to those of amphetamines. In experiment 1, repeated administration of *d*-amphetamine with a paired drug produced increased activity like that reported in the case of repeated administration of amphetamine alone (Hayashi et al., 1980; Segal & Mandell, 1974). Since activity counts in three groups with saline after conditioning increased to a greater extent than before conditioning, it may be considered that the injection procedure and/or environmental stimuli served as conditioned stimuli in increasing the activity counts. Both pentobarbital and caffeine alone increased activity counts after conditioning in the respective drug groups. This fact may indicate that the pharmacological effects of these drugs have cueing effects in increasing activity counts, although the possibility of cross sensitization between *d*-

TABLE 2. Mean Number of Responses of Rats With Standard Deviation Under Differential Reinforcement of Low Rate Schedule.

Session	Combination of Pairing	Number of Responses during 30-min Period	
		Control Group ($N = 6$)	Experimental Group ($N = 5$)
Baseline	No Injection and No External Stimuli	90.0 + 7.5	89.6 + 3.9
Pairing	IMP 2 mg/kg, s.c., Saline 1 ml/kg, s.c., External Stimuli	83.3 + 4.9	—

amphetamine and the paired drugs cannot be excluded. According to the results of the cross tests, caffeine increased activity counts after conditioning regardless of the group. This increase seems to generalize from one drug to the other, but the rule for the generalization remains unclear.

In experiment 2, the increase in the number of responses with the combination of imipramine plus external stimuli and without methamphetamine may indicate that the combination of the stimuli served as a conditioned stimulus, although cross sensitization may be a factor. Administration of either imipramine or saline played a more important role in increasing the number of responses than did the external stimuli, because the external stimuli alone failed to increase the number of responses.

In summary, a possible mechanism by which the behavioral effects of amphetamines may be conditioned by other drugs is worth considering. The findings in the present study suggest that the recurrence of amphetamine psychosis can be developed by a respondent conditioning mechanism being triggered by other drugs.

Visual Perception Process in Amphetamine Psychosis and Schizophrenia[1]

Takuya Kojima, M.D.,[2,3] Eisuke Matsushima, M.D.,[3] Hisayuki Iwama, M.D.,[3] Harunobu Ando, M.D.,[3] Hirobumi Moriya, M.D.,[3] Katsumi Ando, M.D.,[3] Ryo Takahashi, M.D.,[3] and Yasuo Shimazono, M.D.[4]

In daily practice, the facial expression and eye movements of patients are observed to understand the mental state. In order to observe the eye movements of psychotic patients while viewing a picture we have utilized an eye mark recorder. In the previous study (Moriya et al., 1979; Ando et al., 1979) it was reported that chronic schizophrenics and their relatives had less frequent eye movements and a more limited area of inspection than normal controls. The result suggested that eye movements could be considered as a marker for susceptibility for schizophrenia.

Amphetamine psychosis and schizophrenia are very similar symptomatically. The flashback phenomenon of amphetamine psychosis may give us valuable information concerning relapse of schizophrenia. Therefore, we compared the eye movements of amphetamine psychosis with schizophrenia and examined the difference in visual perception process between both psychoses.

Subject and Method

Twenty-eight methamphetamine psychotics, 30 chronic schizophrenics, and 30 normal controls were examined. The two patient groups were on neuroleptic medication. All amphetamine psychotics showed delusion at the time of admission to the hospitals. The amphetamine psychotics were diagnosed by DSM-III criteria and a urine test positive for amphetamine. The chronic schizophrenics were inpatients of mental hospitals and were diagnosed by DSM-III criteria. Most of them were residual and disorganized type.

The subject was asked to sit in a chair 1.5 m in front of a screen and an eye-mark recorder was placed on his/her head. Three geometric figures were projected on the screen (the first and the other two partially different figures are shown in Figure 1). The width of the figure is 0.9 m on the screen and the angle of sight is 20 degrees. The eye movements and fixation points during perception of the figure were examined.

The test procedure is as follows:

1) Each subject was shown an "S"-shaped figure for 15 sec.

2) The subject was then asked to draw the picture immediately after viewing it.

3) Two other figures partially different from the original were then shown in turn for 15 sec. The subject was requested to look at the figures, comparing them with the original in order to answer the question, "Are there any differences between this figure and the first one?" After they finished answering, another question, "Are there any other differences?" was asked. These questions were asked for each figure.

4) The subject was then shown the original and told to look carefully at it in order to draw it again.

5) Finally, the subject was asked to draw the picture.

The eye-mark recorder consists of a helmet which is equipped with very small video cameras attached to the left and right sides of the helmet and another camera attached to the top of the helmet. The side cameras record

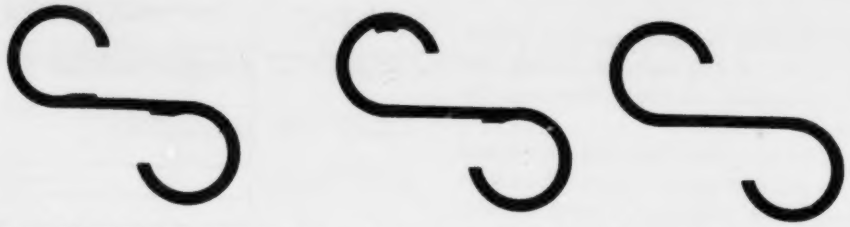

FIGURE 1. The original (left hand figure) and two other partially different figures were projected on the screen in turn.

the lights reflected on the eye balls. The camera on the top of the helmet records the figure on the screen. These three recordings are mixed into one and recorded on a videotape-recording system. This technique enables one to see the eye-fixation points and eye movements simultaneously on the figure. The recorded data are analyzed with a computerized analyzing system and slow motion replay of the video recorder.

Results

Figure 2 demonstrates the sequence of eye movements and fixations of an amphetamine psychotic patient, a schizophrenic patient, and a normal control during the first 5-sec viewing of the "S"-shaped figure. The number on the figure shows the order of eye fixations. The eyes moved less frequently and the moving range of the fixations was much more limited in the schizophrenic patient and amphetamine psychotic patient than in the normal control. The moving range of the fixations was also more limited in the schizophrenic patient than in the amphetamine psychotic patient.

Elementary Components of Eye Movements

The elementary components of eye movements consist of: number of eye fixations, eye-tracking length, and eye-fixation time. Eye-tracking length is the distance between two eye fixations. Eye-fixation time is the

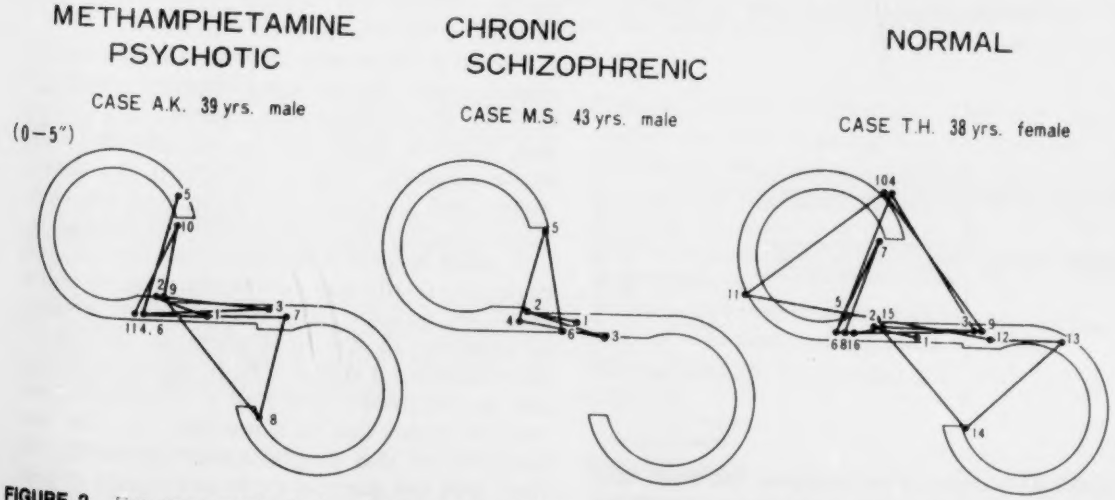

FIGURE 2. Eye movements during first 5 sec of viewing. The number on the figure shows the order of eye fixation. The eyes moved less frequently and the moving range of the fixations was much more limited in the schizophrenic and amphetamine psychotic patients than in the normal control. The moving range of the fixations was also more limited in the schizophrenic patient than in the amphetamine psychotic patient.

time that eyes remain focused on one point. These components of eye movements of the subjects were analyzed during viewing the original figure for 15 sec.

The number of eye fixations was measured (Figure 3). The mean number of eye fixations of the amphetamine psychotics and schizophrenics was less than that of normal controls ($p < .01$). There was no significant difference between amphetamine psychotics and schizophrenics.

The mean eye-fixation time of the amphetamine psychotics and schizophrenics was greater than that of normal controls ($p < .01$). There was no significant difference between amphetamine psychotics and schizophrenics.

Figure 4 shows the total eye-tracking length. The total eye-tracking length represents the combined eye-tracking length for 15 sec. The schizophrenics had shorter eye-tracking length than amphetamine psychotics ($p < .01$). The amphetamine psychotics also had shorter eye-tracking length than normal subjects ($p < .05$). Each group was significantly different from the other two groups.

From the results of components of eye movements, it was found that there was no difference in number of eye fixations and eye-fixation time between amphetamine psychotics and schizophrenics, but remarkable differences in eye-tracking length between them.

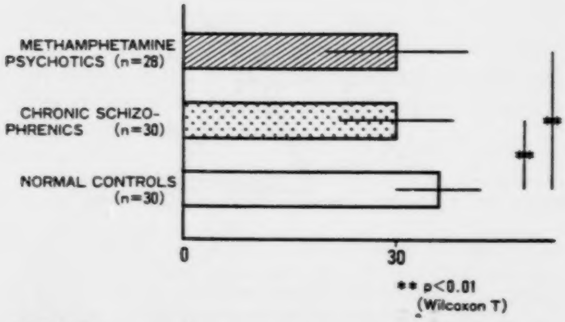

FIGURE 3. Number of eye fixations. The mean number of eye fixations of the amphetamine psychotics and schizophrenics were less than those of normal controls respectively ($p < .01$). There was no significant difference between amphetamine psychotics and schizophrenics.

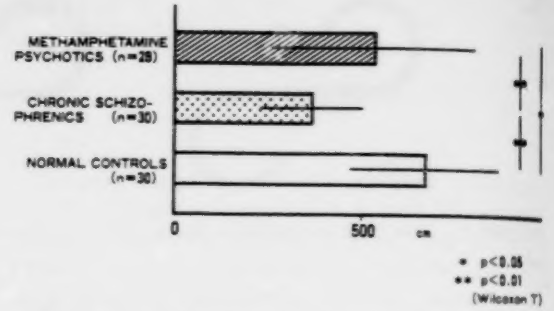

FIGURE 4. Total eye-tracking length. The schizophrenics had shorter eye-tracking length than amphetamine psychotics ($p < .01$). The amphetamine psychotics also had shorter eye-tracking length than normal controls ($p < .05$). Each group was significantly different from the other two groups.

Eye Movements Following Verbal Stimuli (Responsive Search Score)

The subjects were asked to answer the question "Are there any differences between this figure and the original one?" After they finished answering, we asked them "Are there any other differences?" In this situation we can observe the active attitude of the subjects to try to ascertain more information accompanied with the question. The eye movements during this search were scored and called the responsive search score.

Figure 5 shows how to score the responsive search score for an amphetamine psychotic patient, a schizophrenic patient, and a normal control. Each figure was divided into seven sections. The incidence of eye movements and fixations on these sections were scored during the response to the final question; each subject was shown two figures. For example, in the top figure the amphetamine psychotic patient fixed his eyes on 6 sections in response to the final question and therefore received a score of 6. In the bottom figure he received a score of 5. His total score was 11 points out of a possible 14. The eye fixations of this amphetamine psychotic patient and the normal control covered almost all of the sections and the total score was 11 and 12 points, respectively. The schizophrenic patient's eye movements were more restricted with a total score of 5 points.

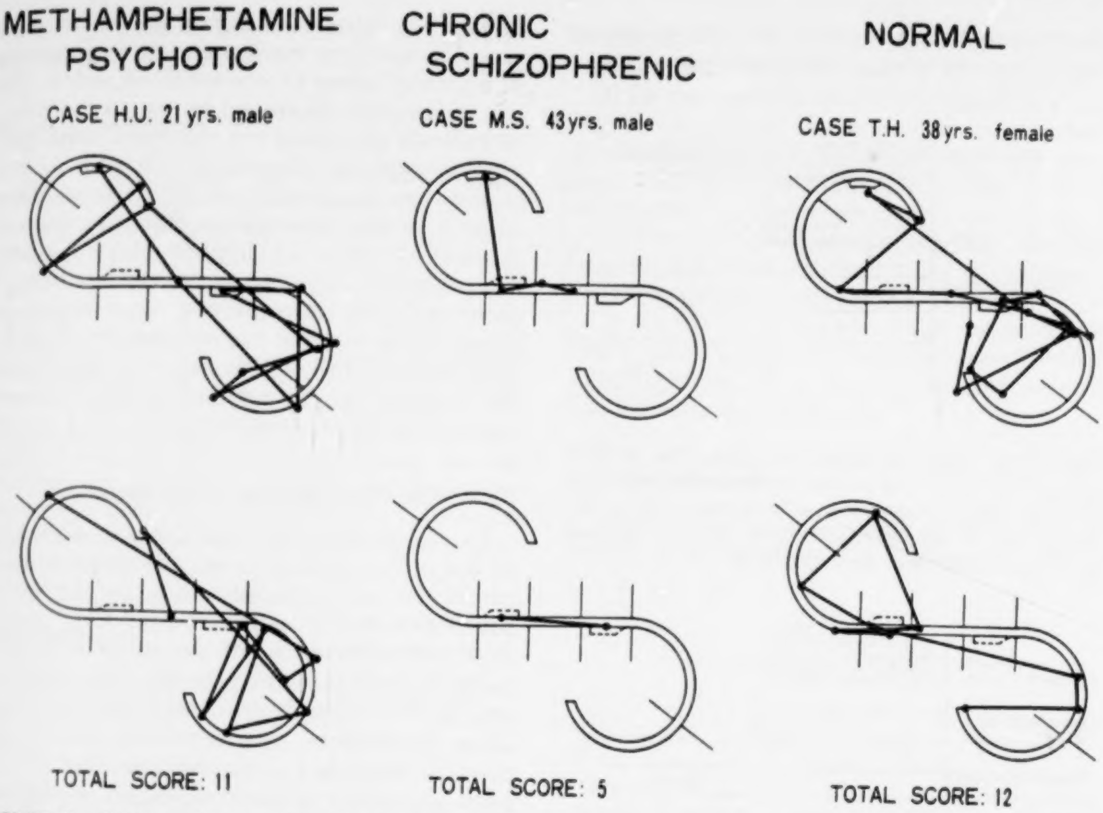

FIGURE 5. Scoring of the responsive-search score. Each figure was divided into 7 sections. The incidence of eye movements and fixations on these sections was scored during the response to the final question. The scores for the two figures, illustrated at the top and bottom, were totaled. The eye fixations of the amphetamine psychotic patient and normal control covered almost all of the sections; total score was 11 and 12 points, respectively. The schizophrenic patient's eye movements were more restricted with a total score of 5 points.

Figure 6 shows the results of the responsive search score. The amphetamine psychotics and normal controls had higher responsive search scores than schizophrenics ($p < .01$). There was no significant difference between amphetamine psychotics and normal controls.

In the analysis of eye movements following the question, it was found that amphetamine psychotics showed much better response to the question than schizophrenics.

Reproduced Picture

The "S"-shaped figure was drawn by subjects and it was evaluated by our criteria (Kojima et al., 1985). Figure 7 shows the evaluation score of the reproduced picture of the first and second drawing. The top figure shows the first drawing and the bottom figure shows the second drawing. In the first and second drawings, amphetamine psychotics had evaluation scores as low as schizophrenics and they in turn had lower scores than normals.

The amphetamine psychotics drew the picture of the original figure as incorrectly as schizophrenics in comparison with normal controls.

Drug Influence

The influence of neuroleptic drugs must be considered. We examined the correlation with "linear regression" between all measures of the eye movements and dosage of chlorpromazine in schizophrenics. There was no significant correlation between them.

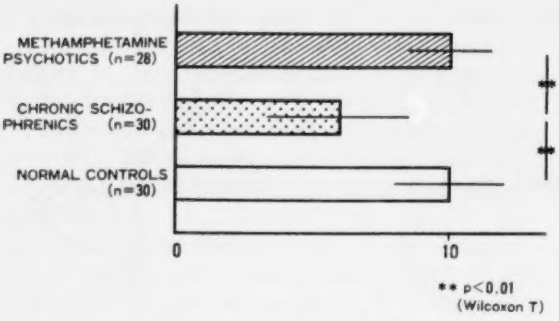

FIGURE 6. Responsive-search score. The amphetamine psychotics and normal controls had higher responsive-search scores than schizophrenics ($p < .01$). There was no significant difference between amphetamine psychotics and normal controls.

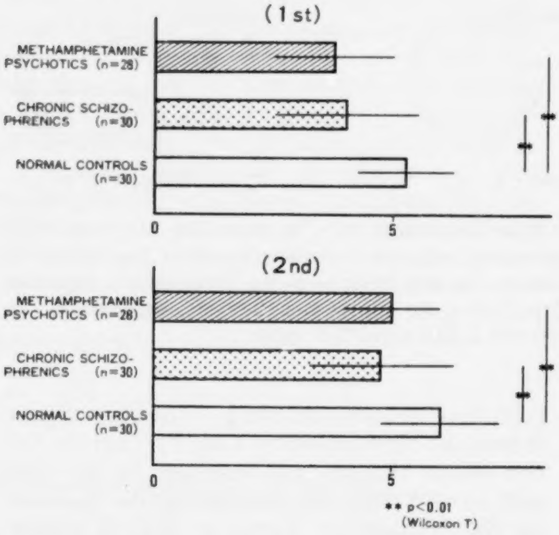

FIGURE 7. Reproduced picture scores. The top figure shows the first drawing and the bottom figure shows the second drawing. In the first and second drawings, amphetamine psychotics had an evaluation score as low as schizophrenics and they in turn scored lower than normals.

Comments

Many researchers have reported the dysfunction of pursuit eye movements in schizophrenia beginning with P. Holzman in 1973. Since 1972 (Moriya et al.) we have been studying saccadic eye movement during viewing of a picture using an eye-mark recorder. The eye movement measured by us is considered to indicate the visual behavior and visual perception and/or cognition. Therefore, our studies are remarkably different from those of pursuit eye movements. But it is interesting that the results (1979) in which not only schizophrenics but also their relatives showed abnormal eye movements, are similar to those of pursuit eye movements by P. Holzman et al. (1974). In this paper we focused on the comparison between the amphetamine psychotics and schizophrenics.

Elementary Components of Eye Movement

In comparison of elementary components of eye movements between the amphetamine psychotics and schizophrenics, amphetamine psychotics had a longer eye-tracking length than schizophrenics but the other two components were similar to those of schizophrenics. At first it had been considered that these three components might reflect equally the positive attitude to the environment of patients. But the eye-tracking length of amphetamine psychotics seemed to be dissociated from the other two components. The eye-tracking length of schizophrenics was negatively correlated with negative symptoms such as blunted affect. This may suggest that amphetamine psychotics have less negative symptoms than schizophrenics but more than normal controls.

Eye Movements Following Verbal Stimuli

The amphetamine psychotics and normal controls searched the figure quickly as if they had tried to confirm it again after the question, "Are there any other differences?" But schizophrenics hardly searched the figure. This visual behavior was scored as the responsive-search score. The responsive-search score of amphetamine psychotics was as high as that of normals and was higher than that of schizophrenics. The results of responsive-search score are consistent with clinical findings (reported by Prof. Tatetsu) that amphetamine psychotics showed much better response to persons other than schizophrenics in spite of their having delusions and/or hallucinations.

Reproduced Picture

The amphetamine psychotics and schizophrenics drew the original figure less correctly than normal controls. The previous study (Moriya, 1979; Shimazono et al., 1983) indicated that the chronic schizophrenics and their relatives drew it less correctly than normals. Kojima et al. (1985) reported that amphetamine psychotics and schizophrenics did not look at the important areas of the figure long enough to recognize it. The results of the reproduction quality and the eye movements suggest that amphetamine psychotics have poor information aquisition and disturbance of the visual-perception process.

Drug Influence

There was no significant correlation between all measures of the eye movement and dosage of chlorpromazine in schizophrenics. In many cases limited eye movements were found in the parents of schizophrenics (Moriya, 1979). These data suggest that the abnormal eye movement of schizophrenics is not due to the influence of medication.

Finally, it was concluded that the amphetamine psychotics in general had very similar eye movements, although with several different components of eye movements, compared to schizophrenics. These results suggest that the amphetamine psychotics may have a little different disturbance of visual perception and/or cognition than schizophrenics.

Summary

1) The eye movements of 28 methamphetamine psychotics, 30 chronic schizophrenics, and 30 normal controls were examined using an eye mark recorder.

2) In the analysis of the elementary components of eye movements, there was a remarkable difference in eye-tracking length between the amphetamine psychotics and schizophrenics but no difference in other components between them.

3) In the analysis of eye movement following verbal stimuli the amphetamine psychotics showed much better response to the question than the schizophrenics (high responsive-search score).

4) The amphetamine psychotics drew the original figure as incorrectly as schizophrenics in comparison with normal controls.

5) These data suggest that the amphetamine psychotics may have a little different disturbance of visual perception and/or cognition than schizophrenics.

Changes in Receptor Stimulated Phosphoinositide Hydrolysis in Brain During Ethanol Administration, Aging, and Other Pathological Conditions*

Fulton T. Crews, Ph.D.,[1] Rueben A. Gonzales, Ph.D.,[1] Reinhard Palovcik, Ph.D.,[2] M. Ian Phillips, Ph.D.,[2] Cynthia Theiss, M.P.E.,[1] and Mohan Raizada, Ph.D.[2]

Recent studies in a variety of cell types have indicated that receptor activated hydrolysis of phosphoinositides is an early event in the transduction of hormone and neurotransmitter signals (Berridge, 1984). Phosphoinositides are a group of minor membrane phospholipids, e.g., phosphatidylinositol, phosphatidylinositol 4-phosphate, and phosphatidylinositol 4,5-bisphosphate (PIP_2). Hormones and transmitters bind to their individual receptors and activate a specific phospholipase C which hydrolyzes the phosphoinositides into two separate second messengers, diacylglycerol and inositol 1,4,5-trisphosphate (Berridge, 1984). Diacylglycerol is a lipid which induces an allosteric activation of a phosphatidylserine, calcium dependent protein kinase frequently referred to as C kinase (Nishizuka, 1984). C kinase has very high activity in nervous tissue. Whereas diacylglycerol is formed from the hydrolysis of any of the phosphoinositides, inositol 1,4,5-trisphosphate is formed only from phospholipase C hydrolysis of phosphatidylinositol 4,5-bisphosphate. Inositol 1,4,5-trisphosphate releases calcium from the endoplasmic reticulum of a number of cell types (Streb et al., 1983). Intracellular calcium can activate calcium dependent protein kinases as well as activating calcium dependent ion channels. In some cell types there is a synergism between the calcium and diacylglycerol signals, whereas in other cell types separate functions appear to be involved.

The number of receptors linked to phosphoinositide hydrolysis in brain is not presently known. Two receptors which clear-

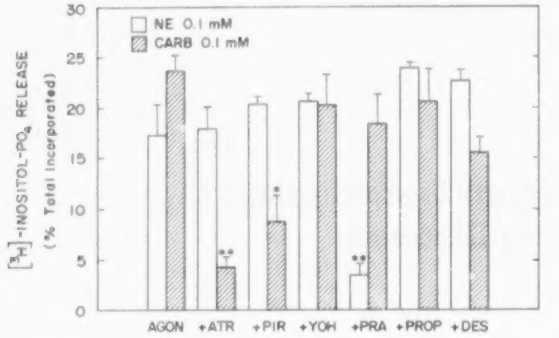

FIGURE 1. Effects of antagonists on cholinergic and adrenergic stimulated inositide hydrolysis in rat cortical slices. Slices were prepared, labelled with [^{3}H]inositol, stimulated with norepinephrine or carbachol, and the released [^{3}H]inositol phosphates were analyzed as described in Gonzales and Crews (1985a). Nonstimulated values have been subtracted from the stimulated to obtain net release. $^{**}p < 0.01$ and $^{*}p < 0.05$ by analysis of variance and Newman-Keuls test.

ly cause a marked stimulation of phosphoinositide hydrolysis in brain are the muscarinic-cholinergic and the α_1-adrenergic receptor (Figure 1). Stimulation of inositide hydrolysis by norepinephrine is blocked by α_1-adrenergic antagonists. Among brain regions the hippocampus has the largest response to norepinephrine, although the striatum, cerebral cortex, and hypothalamus also have large responses (Gonzales and Crews, 1985a). Similarly, acetylcholine and carbachol, a prototypical cholinergic agonist, stimulate phosphoinositide hydrolysis in the cerebral cortex, hippocampus, striatum, and to a lesser extent in most other brain regions except the cerebellum where there was only a small response (Gonzales and Crews, 1984). Cholinergic stimulation of inositide hydrolysis in the cerebral cortex is inhibited by atropine, the muscarinic antagonist, as well as pirenzepine, the selective M1 muscarinic antagonist (Figure 1). Studies of a variety of cholinergic agonists indicate that certain drugs, such as oxotremorine, which were previously thought to be good cholinergic agonists, are actually weak partial agonists for the stimulation of phosphoinositide turnover (Figure 2). Furthermore, oxotremorine has been shown to inhibit stimulation of inositide hydrolysis by full cholinergic agonists. This suggests that in vivo studies with oxotremorine may actually be looking at cholinergic antagonist actions and not agonist responses. Since the predominant cholinergic receptors in the cerebral cortex are muscarinic it is likely that much of cortical cholinergic neurotransmission is mediated by M1 muscarinic receptors coupled to phosphoinositide hydrolysis.

To fully understand cholinergic and adrenergic neurotransmission the mechanism by which muscarinic-cholinergic and α_1-adrenergic receptors couple to phospholipase C must be understood. Receptor purification studies have suggested that the neurotransmitter recognition site, i.e., the receptor, is not itself a phospholipase. Furthermore, cholinergic and adrenergic agonists are less than additive in certain brain regions suggesting that the two receptors share the same phospholipase C and phosphoinositide pool (Gonzales and Crews, 1985a). Most phospholipases are found in lysosomes, are not specific for any particular lipid, and are activated by calcium. Phosphoinositide specific phospholipase C is likely to be in the plasma membrane in close

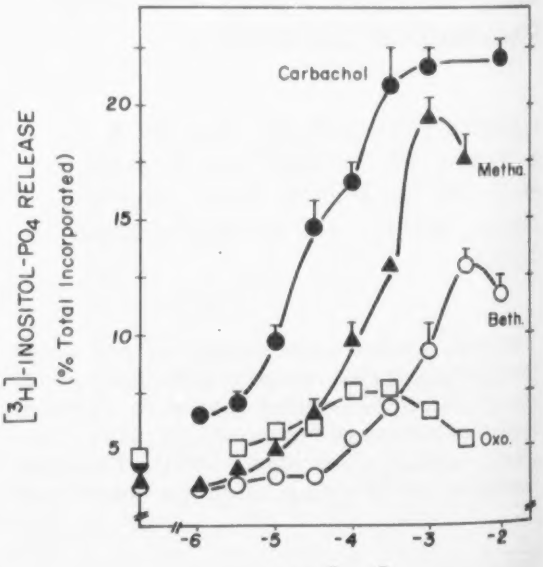

FIGURE 2. Concentration-effect curves for cholinergic agonists on inositide hydrolysis in rat cortical slices. Results were obtained as described in Figure 1 for carbachol, methacholine (metha), bethanechol (beth), and oxotremorine (oxo).

proximity to receptors and the inositol phospholipids. The β-adrenergic receptor has been shown to stimulate the enzyme adenylate cyclase through an interaction with a specific guanine nucleotide binding protein (Lefkowitz et al., 1983). Recent studies have suggested that receptors coupled to inositide hydrolysis may also require a guanine nucleotide binding protein, which is different from that involved with adenylate cyclase and cyclic-AMP formation, for the activation of phospholipase C (Cockroft and Gomperts, 1985; Litosch et al., 1985). Incubation of cerebral cortical membranes with the guanine nucleotide Gpp(NH)p and/or calcium stimulates the hydrolysis of phosphoinositides (Figure 3), and PIP_2 may be a substrate for Gpp(NH)p activated phospolipase C (Gonzales and Crews, 1985b). Since both guanine nucleotides and calcium can activate phosphoinositide hydrolysis in cerebral cortical membranes, it is possible that the phosphoinositide cascade in brain can be activated by receptors as well as through increases in cellular calcium. In any case, these studies suggest that when muscarinic-cholinergic or α_1-adrenergic receptors are occupied by an agonist they interact with a guanine nucleotide binding protein in the plasma membrane to activate phosphoinositide specific phospholipase C and thereby release the two second messengers, diacylglycerol and inositol 1,4,5-trisphosphate.

Additional evidence supporting the role of phosphoinositide hydrolysis in neurotransmission has been obtained using primary cell cultures and electrophysiological studies of neuronal responses to cholinergic drugs. A comparison of primary cultures composed of almost exclusively neurons or glia indicate that cholinergic and adrenergic receptor stimulated phosphoinositide hydrolysis is far more robust in neurons than glia (Gonzales et al., 1985). Electrophysiological studies of the hippocampal pyramidal cell response to carbachol have found that the concentration response curve and time course for excitation of pyramidal cells is almost identical to that found for phosphoinositide hydrolysis. Furthermore, carbachol is a full agonist and oxotremorine a weak partial agonist at stimulation of pyramidal cell firing similar to that found for phosphoinositide hydrolysis (Figure 4). Muscarinic receptors have been shown to decrease potassium conductances in hippocampal pyramidal cells (Cole and Nicoll, 1983). Taken together, these data suggest

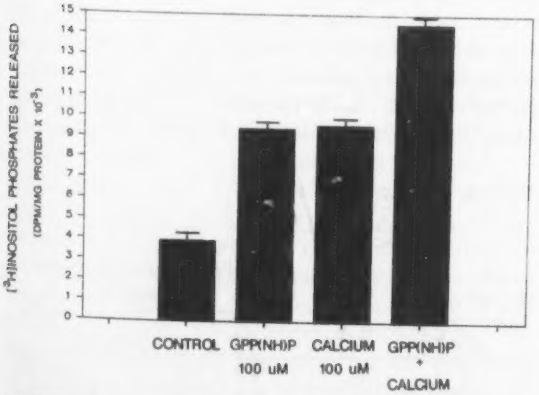

FIGURE 3. Guanine nucleotide and calcium activated inositide hydrolysis in rat cortical membranes. Membranes were prepared from prelabelled cortical slices as described in Gonzales and Crews (1985b). Gpp(NH)p and calcium were added to the membrane preparation and [^{3}H]inositol phosphates released were analyzed by anion exchange chromatography.

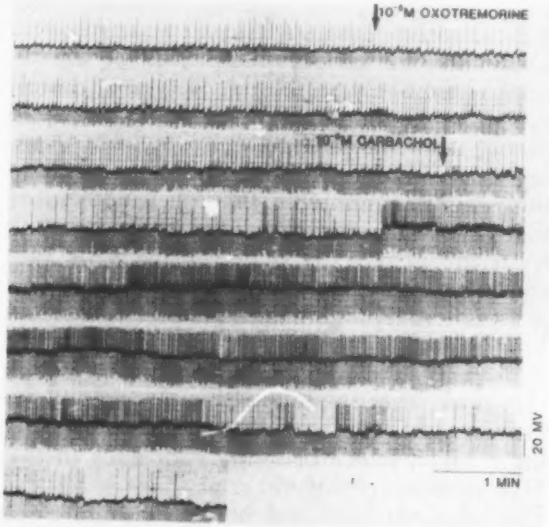

FIGURE 4. Effect of cholinergic agonists on electrophysiology of hippocampal pyramidal cells. This intracellular recording of a CA1 hippocampal pyramidal neuron response shows a slight increase in firing rate to 10 μM oxotremorine and a much larger increase in firing rate and depolarization to 10 μM carbachol.

that activation of muscarinic receptors initiates a cascade in neurons which involves phosphoinositide hydrolysis to form second messengers. The second messengers may then lead to activation of protein kinases and phosphorylation of membrane potassium channels which may alter neuronal membrane conductance.

The discovery that cholinergic-muscarinic and α_1-adrenergic mediated neurotransmission involves phosphoinositide hydrolysis suggests that changes in this response may underlie phenomena such as receptor plasticity, disease states, and drug effects. Experiments with primary neuronal cultures have shown that continuous stimulation of neurons with norepinephrine causes an 80-percent decrease in the α_1-adrenergic response within 2 hours without changing the number of α_1 receptors (Figure 5). Stimulation for longer times leads to the loss of α_1-adrenergic receptor binding sites with a maximum loss reached after approximately 24 hours of stimulation with norepinephrine (Gonzales et al., unpublished). A similar uncoupling of muscarinic-cholinergic receptors has been reported in astrocytoma cells (Masters et al., 1985). These findings indicate that there are rapid changes in the responsiveness of these two receptors. Drugs which increase synaptic concentrations of norepinephrine or acetylcholine are likely to induce this type of desensitization in the brain. Recent studies comparing neuronal primary cultures from spontaneously hypertensive rats (SHR) with their normotensive controls (WKY) have shown that the α_1-adrenergic receptors in neurons from the genetically hypertensive SHR rats are poorly coupled to phosphoinositide hydrolysis. Norepinephrine stimulated inositide hydrolysis is significantly greater in WKY neurons than in SHR neurons (Table 1). Furthermore, there are more α_1-receptor binding sites in SHR than WKY neurons indicating a much lower coupling efficiency in the SHR neurons (Feldstein et al., 1986). Muscarinic-receptor sites and phosphoinositide responses are identical in SHR and WKY neurons. Thus α_1-adrenergic and muscarinic-cholinergic receptors rapidly change their coupling efficiency and alterations in coupling of α_1-adrenergic receptors may be related to the pathology of hypertension.

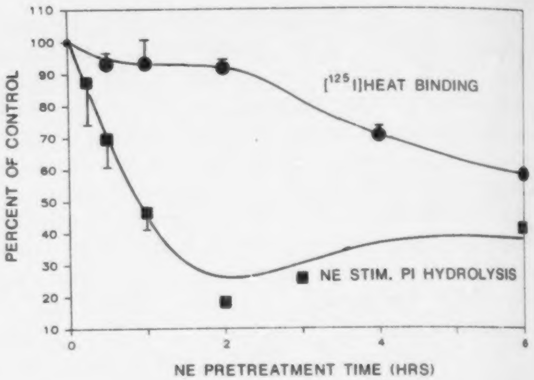

FIGURE 5. Norepinephrine induced loss of α_1-stimulated inositide hydrolysis and α_1-binding sites in neuronal primary cultures. Neuronal cultures were prepared from neonatal WKY rat brains and exposed to 10 μM norepinephrine for various times. Inositide hydrolysis in prelabelled cultures was measured after washing out the norepinephrine and adding either buffer or 10 μM norepinephrine back to the cultures in the presence of 10 mM LiCl. Alpha$_1$-binding sites were assessed by measuring the level of [^{125}I]HEAT binding in the presence and absence of 1 mM naphazoline.

Ethanol is one of the most widely used drugs. It does not have a specific receptor, but appears to alter neurotransmission by modifying membrane viscosity. Since α_1 and muscarinic receptor mediated neurotransmission involves membrane lipid hydrolysis, it is not surprising that ethanol can disrupt adrenergic and cholinergic neurotransmission. In the cerebral cortex the effects of various concentrations of ethanol on membrane viscosity parallel the inhibition of norepinephrine stimulated inositide hydrolysis (Figure 6).

TABLE 1

Norepinephrine Concentration (μM)	N	WKY	SH
		[^{3}H]inositol phosphates released (MEAN + SEM) (% total ^{3}H incorporated)	
0	4	18.2 ± 0.8	19.0 ± 0.9

0.3	2	25.5 ± 0.9	21.4 ± 3.2
1	4	30.9 ± 1.1	25.2 ± 1.1**
3	4	35.0 ± 1.2	28.5 ± 1.3**
10	4	34.5 ± 1.2	29.2 ± 1.1**
100	3	35.3 ± 1.5	27.3 ± 1.2**

Norepinephrine stimulated inositide hydrolysis in neurons from whole brains of WKY and SH rats. Inositide hydrolysis was determined as described in Figure 5.
**$p < 0.01$ by analysis of variance and Newman-Keuls test.

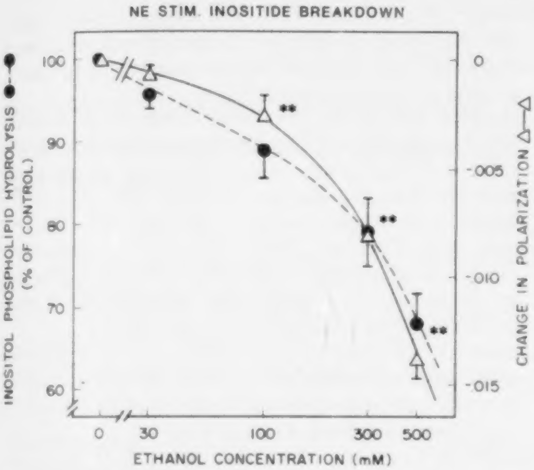

FIGURE 6. Effects of ethanol on rat cortical synaptosomal membrane organization and norepinephrine stimulated inositide hydrolysis. Norepinephrine (100 μM) stimulated inositide hydrolysis was measured as described in Figure 1. Membrane order was estimated by measuring the fluorescence polarization of diphenylhexatriene in purified synaptosomes.

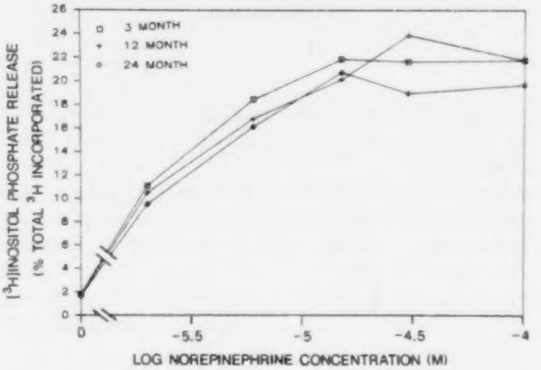

FIGURE 7. Alpha$_1$-stimulated inositide hydrolysis in cortical slices from 3-, 12-, and 24-month old Fisher 344 rats. Inositide hydrolysis was measured as described in Figure 1. No significant differences were found between any of the age groups (analysis of variance).

This change in responsiveness does not appear to be due to a loss of receptor sites, but due to an uncoupling of the α_1 response. Cerebral cortical muscarinic receptor-stimulated inositide hydrolysis is not very sensitive to ethanol (Gonzales et al., unpublished).

Studies of cholinergic neurotransmission have indicated that there is a decrease in the release of acetylcholine in the cerebral cortical synaptosomes (Meyer et al., 1984) and a decrease in the hippocampal electrophysiological response to acetylcholine in senescent rats (Lippa et al., 1981). However, no difference in either α_1-adrenergic (Figure 7) or muscarinic-cholinergic (Figure 8) stimulated phosphoinositide hydrolysis in cortical slices was found between 3-, 12-, and 24-month old Fisher 344 rats. Thus, adrenergic and cholinergic stimulation of phosphoinositide hydrolysis does not appear to be altered in the cerebral cortex during aging. Further studies are required to determine if changes in responsiveness occur at other sites in the phosphoinositide cascade or in other brain regions during aging.

In summary, α_1-adrenergic and muscarinic-cholinergic receptor mediated neurotransmission is thought to be mediated by the hydrolysis of phosphoinositides and the formation of the second messengers diacylglycerol and inositol 1,4,5-trisphosphate. Responsiveness in this cascade changes rapidly during agonist stimulation and/or in the presence of drugs such as ethanol. A decrease in α_1-receptor responsiveness may be related to genetic hypertension. Future studies on these receptor mechanisms are required to fully understand their roles in neurotransmission, drug responses, and central nervous system pathology.

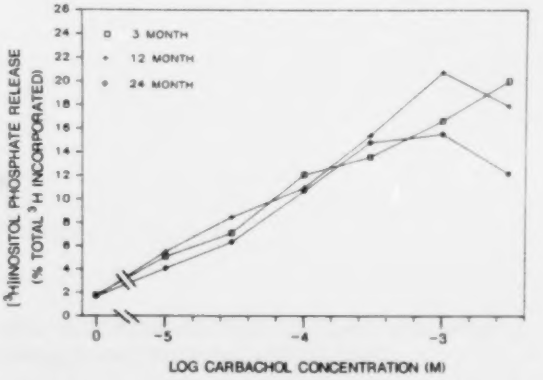

FIGURE 8. Muscarinic cholinergic-stimulated inositide hydrolysis in cortical slices from 3-, 12-, and 24-month old Fisher 344 rats. Results obtained were as in Figure 7.

"Autocannibalism" of Membrane Choline-Phospholipids: Physiology and Pathology

Jan K. Blusztajn, Ph.D.,[1] Pamela G. Holbrook, M.S.,[1] Michael Lakher, M.S.,[1] Mordechai Liscovitch, Ph.D.,[1] Jean-Claude Maire, Ph.D.,[2] Charlotte Mauron, B.S.,[1] U. Ingrid Richardson, Ph.D.,[1] Mariateresa Tacconi, Ph.D.,[3] and Richard J. Wurtman, M.D.[1]

Cholinergic neurons derive their choline from the circulation [choline crosses the blood-brain barrier via a facilitated diffusion mechanism (Pardridge et al., 1979)] or from its synthesis in situ (Blusztajn and Wurtman, 1981). Within cholinergic neurons choline can undergo two transformations: it may be acetylated by choline acetyltransferase (CAT) to form the neurotransmitter acetylcholine (ACh), or it may be incorporated into choline phospholipids (Ch-PL) [phosphatidylcholine (PtdCho), sphingomyelin, or plasmalogens] via the CDP-choline (Kennedy and Weiss, 1956) or base-exchange (Porcellati et al., 1971; Abdel-Latif and Smith, 1972) pathways. The authors hypothesize that a dynamic equilibrium exists between choline's reversible fluxes into and out of ACh and Ch-PL, and that these fluxes are well regulated in order to maintain both adequate ACh synthesis and the functional integrity of membranes (Ch-PL are the major lipid components of all biological membranes). However, under some circumstances, the choline obtained from Ch-PL degradation may be used for ACh synthesis; for example when the neuron is persistently firing frequently, or when the supply of free choline is inadequate for ACh synthesis (because the neuron makes too little choline or is unable to take up enough of it from the brain's extracellular fluid). The rate at which Ch-PL are hydrolyzed to yield free choline may transcend the neuron's ability to resynthesize these molecules, resulting in the net "autocannibalism" of its membranes. The choline obtained by "autocannibalism" could derive from the general metabolic "pool" of choline phospholipids, or perhaps from a pool specifically mobilized for that purpose. Membrane phospholipids like PtdCho are compartmented in three ways: by their subcellular localization (for example, synaptic vesicles vs. plasma membranes); by their fatty acid composition; and by their mode of synthesis [methylation of phosphatidylethanolamine (PtdEtn) vs. incorporation of pre-existing choline via the CDP-choline or base-exchange pathways] (*see* below). Excessive destruction of membrane PtdCho might lead to changes in membrane composition (for example, in the ratios of PtdCho to other phospholipids, or to proteins) or to a loss in total membrane surface. Either alteration could affect the neuron's functional properties and even its viability. Such changes would be most likely to occur in nerve terminals (the neuronal structures that are specialized for neurotransmitter synthesis and release) initially damaging them, and only later affecting cell bodies.

This paper describes the relationships between choline, ACh, and Ch-PL in the nervous system, presenting evidence derived from experiments on brain slices, synaptosomes, and cultured cells. Based on these basic studies and clinical observations the authors discuss the possible role of the "autocannibalism" in the pathophysiology of Alzheimer's disease.

Effects of Neuronal Activity on Acetylcholine Release and Phospholipid Turnover

Since CAT has a low affinity for choline and is highly unsaturated with this substrate in vivo (White and Wu, 1973; cf. Blusztajn and Wurtman, 1983), ACh synthesis and re-

lease can be increased by treatments that elevate extracellular choline levels. The effect of the choline is enhanced in cholinergic neurons that are firing frequently (cf. Blusztajn and Wurtman, 1983). For example, the authors measured ACh release from rat striatal slices superfused with or without choline (Maire and Wurtman, 1985). In the absence of free choline, ACh was released spontaneously at a rate of 7.5 ± 1.3 pmol/mg protein/min (mean ± S.D.). Electrical field stimulation (15 Hz for 30 min) accelerated this release (25.6 ± 5.9 pmol/mg protein/min), and addition of choline (20 μM) to the superfusate significantly enhanced both the spontaneous (22.7 ± 5.7 pmol/mg protein/min) and the electrically evoked (37.4 ± 6.7 pmol/mg protein/min) release of the transmitter. Although the amount of ACh in the tissue did not depend on extracellular choline concentration (in this range of choline concentrations) tissue choline contents did increase when choline levels in the superfusate were raised.

The breakdown of membrane PtdCho in neurons can also be accelerated by frequent firing, especially when extracellular choline is unavailable. This was first shown by Parducz et al. (1976) who electrically stimulated the preganglionic trunk of the cat's superior cervical ganglion (in the presence of hemicholinium-3) and observed that the number of synaptic vesicles decreased to 18% that of controls, while ganglionic PtdCho levels fell to 69% of controls. (Other phospholipids were not affected.) These observations indicate that when adequate extracellular choline is not available (e.g., after inhibition of its uptake by hemicholinium-3), vesicular PtdCho is used to supply choline for ACh synthesis. The authors have observed similar phenomena in their striatal slices preparations: In the absence of exogenous choline, the combined efflux of *choline + ACh* into the superfusate was 75-pmol/mg protein/min; however, the decrease in *choline + ACh* within the tissue was only 16 pmol/mg protein/min (Maire and Wurtman, 1985). Thus, an endogenous pool of choline, present within a larger molecule, must have provided the free choline to sustain ACh synthesis and tissue choline and ACh levels. The only known compounds whose pool sizes would be sufficient for this purpose are the Ch-PL. Evidence that these compounds are indeed the source of the free choline is provided by the finding that the amount of phosphate in the phospholipids of the slices also decreased (by 23%) when the slices were stimulated (Mauron and Wurtman, in preparation), i.e., suggesting that neuronal activity accelerated the metabolic degradation of phospholipids. Addition of exogenous choline (20 μM) to the superfusate prevented the loss of phospholipid phosphate from stimulated slices. This suggests either that the apparent acceleration in phospholipid degradation reflected increased need for choline in order to maintain ACh release from cholinergic neurons (i.e., shifting the equilibrium between ACh, choline, and Ch-PL, towards ACh); or a general increase in phospholipid turnover, related to neuronal firing. In the former case the exogenous choline presumably was used to maintain high ACh synthesis, and thus prevented the shift in the equilibrium; in the latter, the choline presumably provided sufficient substrate to allow the rate of Ch-PL synthesis to catch up with their accelerated degradation. Preliminary data suggest that when slices are stimulated in the absence of exogenous choline, the rate of PtdCho synthesis by the de novo methylation pathway (*see* below) is increased (Lakher and Wurtman, unpublished). Perhaps this reflects a mechanism for sustaining membrane PtdCho levels (i.e., when PtdCho degradation is accelerated due to firing), or one to maintain the appropriate PtdEtn/PtdCho ratio within the membrane (PtdCho degradation would tend to increase this ratio; PeMT activation would decrease it by converting PtdEtn to PtdCho).

Relationships Between Acetylcholine and Choline Phospholipid Synthesis in a Cholinergic Cell Line, NG108-15

The authors have studied the relationships between Ch-PL and ACh levels in a purely cholinergic cell line, the neuroblastoma × glioma hybrid, NG108–15 (Hamprecht, 1977). The synthesis of ACh in these cells was found to vary with extracellular choline concentrations. When the cells were incubated for 1 hour in the presence of various [^{3}H-methyl]choline concentrations, the accumulation of [^{3}H-methyl]ACh exhibited saturable kinetics, with an apparent K_m of 193 ± 34 μM, and V_{max} of 268 ± 23 pmol/mg protein/hr. At the same time, incorporation of the labeled choline into phosphocholine (an intermediate in PtdCho synthesis) proceeded at a much higher rate (apparent V_{max} = 16.8 ± 1.2 nmol/mg protein/hr) and had a lower apparent K_m (14.9 ± 5.4 μM). Thus choline was more likely to be used in these cells for PtdCho than for ACh synthesis (because choline kinase was more likely than CAT to attack the choline). The authors hypothesized that a treatment that inhibited choline kinase activity in the cells might enhance their formation of ACh, and observed that addition of ethanolamine to the incubation medium (0.5 mM), which suppressed formation of phosphocholine and PtdCho (in a competitive fashion, apparent K_i = 180 μM) did indeed enhance the labeling of [^{3}H-methyl]ACh. These data demonstrate that the dynamic equilibrium between ACh, choline, and Ch-PL can be shifted towards ACh when choline's utilization for Ch-PL synthesis is slowed.

Choline Synthesis in Neurons

Choline is synthesized in brain neurons, de novo, by a multienzymatic pathway; the terminal steps in this pathway, catalyzed by phosphatidylethanolamine N-methyltransferase (PeMT), involve the stepwise methylation of PtdEtn to PtdCho, using S-adenosylmethionine (SAM) as methyl donor. This newly formed PtdCho is hydrolyzed to free choline by a number of phospholipases and other hydrolases. The authors found that free choline constituted 23 percent of the total PtdCho synthesized by synaptosomal PeMT (from [^{3}H-methyl]SAM) during a 30-min incubation period. Furthermore, the enrichment of the free choline pool with newly formed [^{3}H]choline was 50-fold greater than that of the PtdCho pool by newly formed [^{3}H]PtdCho (Blusztajn and Wurtman, 1981). Thus, the relatively small amount of PtdCho synthesized in nerve terminals de novo may have a considerably faster turnover than the bulk of synaptosomal PtdCho. (One might anticipate that PtdCho pool which preferentially provided free choline for acetylcholine synthesis would turn over more rapidly than "storage" PtdCho.) Perhaps this pool has a special fatty acid composition. The bulk of synaptosomal PtdCho contains mainly (77 percent) fatty acids with 0-2 double bonds. However the PtdCho newly synthesized by the methylation has a high proportion (up to 97 percent) of polyunsaturated fatty acids (4-6 double bonds) (Tacconi and Wurtman, 1985), reflecting the fatty acid composition of its precursor PtdEtn (Tacconi and Wurtman, 1985). Synaptosomal PtdCho newly synthesized from preexisting choline molecules either by cholinephosphotransferase-catalyzed reaction (phosphocholine moiety of a cofactor, cytidinediphosphocholine is esterified with a diacylglycerol) or by base-exchange enzyme [free choline is incorporated into PtdEtn or phosphatidylserine (PtdSer) with a concomitant release of free ethanolamine or serine, respectively] also contains higher proportion of polyunsaturated fatty acids (65 percent) (Holbrook et al., 1985) in comparison to the steady state (25 percent) (Breckenridge et al., 1972; Holbrook et al., 1985).

Although the authors showed that the brain synthesized choline molecules de novo both in vivo and in vitro, the question whether this process actually could occur within cholinergic neurons, remained unanswered due to the heterogeneity of brain tissue. The authors therefore used a culture of purely cholinergic cells (human neuroblastoma, LA-N2) in order to address this issue. When the LA-N2 cells were incubated with [^{14}C]ethanolamine for 24 hours, most of the radioactivity in cells was recovered in [^{14}C]PtdEtn; however, 3 to 7 percent of that was present in [^{14}C]PtdCho. Using a newly developed high performance chromatography method (Liscovitch et al., 1985); the authors established that 5 to 10 percent of this PtdCho was apparently hydrolyzed yielding [^{14}C]phosphocholine intracellularly or free [^{14}C]choline which was recovered from the cell growth media (Blusztajn et al., 1986). Thus cholinergic neurons can synthesize choline de novo via the PtdEtn methylation and subsequent PtdCho hydrolysis. Studies now in progress are designed to determine whether some of this choline can be utilized as a precursor of ACh.

"Autocannibalism" and Pathophysiology of Alzheimer's Disease

An overwhelming consensus now exists among investigators that a) certain ACh-releasing brain neurons, the septal neurons projecting to the hippocampus and basal forebrain neurons innervating the cerebral cortices, invariably degenerate in Alzheimer's disease (Bowen et al., 1982; Perry et al., 1978; Wilcock et al., 1982; Wurtman, 1985); b) other neurons (for example, serotonin-releasing neurons in the raphe nucleus; noradrenergic neurons of the locus coeruleus; cortical somatostatin-releasing neurons) are also often afflicted but to a lesser extent; and, c) many neuronal populations are largely unaffected in the disease. If one or more groups of neurons are invariably damaged in Alzheimer's disease, then examination of their biochemical peculiarities may yield insights as to the disease's etiology or to the pathogenetic process that ultimately causes the neurons to die. Moreover, if the deficient neurotransmitter can be implicated in the abnormal behaviors typical of the disease—like ACh in memory loss, or norepinephrine in the impaired ability to sustain attention, or serotonin in disturbances of mood or in aggressiveness—then drugs which substitute for the deficient transmitter or which increase its availability in synapses might be useful in treating the disease.

The authors propose that the selective vulnerability of cholinergic neurons is due to "autocannibalism." The hypothesis begs the question of the etiology of the Alzheimer's disease, focusing instead on why cholinergic neurons are more likely than others to be damaged by the etiologic factor: It applies equally well whether the etiologic factor is present only in diseased cells or is distributed throughout the brain. The factor itself that presumably causes a choline deficiency might be a decrease in choline's production (by de novo synthesis); a decrease in its uptake from the synaptic cleft and extracellular space; or an excessive utilization of choline to form a particular phospholipid. Choline uptake might be impaired if the delivery of oxygen or glucose to the nerve terminals is deficient, perhaps secondary to a diffusion block caused by the perivascular amyloidosis that is characteristic of Alzheimer's disease (Mandybur, 1975). Alternatively, the hypothetical choline deficiency might simply result from its overuse for ACh synthesis, as might happen if the firing frequency of vulnerable neurons is persistently enhanced, or if the presynaptic storage of ACh is impaired. Once cholinergic terminals begin to deteriorate and to release less of the transmitter, it seems likely that surviving, "healthy" terminals might start to release *more* ACh—because the firing frequencies of their neurons will increase or because release is no longer subject to presynaptic inhibition. Increased ACh synthesis might also be expected to increase the demand for its precursor, choline, within "healthy" terminals, a process which might ultimately lead to "autocannibalism" in these terminals as well.

Several pieces of clinical evidence are consistent with the "autocannibalism" hypothesis of the pathogenesis of Alzheimer's disease:

1. It is the terminals of cholinergic neurons, in the cerebral cortex, and not the perikarya, in the basal forebrain, which apparently degenerate first in Alzheimer's disease (Pearson et al., 1983; Perry et al., 1985). This is consistent with the fact that most of the neurons' ACh is formed in the pre-synaptic terminals.

2. Only long-axon cholinergic neurons are affected by the disease process: the short-axon interneurons in the striatum are spared. Perhaps the short-axon neurons can more easily resynthesize their membranes because Ch-PL are more readily available to them through axoplasmic transport (Abe et al., 1973; Droz et al., 1981). This transport would occur over a considerably shorter distance than that separating cholinergic perikarya in the nucleus basalis or septum from terminals in the frontoparietal cortex or hippocampus.

3. Patients with Down's syndrome invariably develop pathological signs (senile plaques and tangles) indistinguishable from those observed in the brains of people with Alzheimer's disease (*see* Epstein, 1983 for a review) as well as a decrease in cortical CAT activity (Yates et al., 1980). Brain PtdEtn and PtdSer purified from autopsy specimens of

fetuses affected with this genetic disorder exhibit abnormal fatty acid composition (Brooksbank et al., 1985), suggesting that abnormal phospholipid metabolism might also be found in the brains of people with Alzheimer's disease.

4. PtdCho and PtdEtn are metabolized by brain phospholipases A (PLA) and lysophospholipases to form glycerophosphocholine or glycerophosphoethanolamine, respectively. The amounts of glycerophosphocholine in brain autopsy specimens from patients that died with Alzheimer's disease reportedly are 3.6 fold higher than those present in samples from normal people (Barany et al., 1985). (The amounts of PtdCho and PtdEtn were found to be unchanged in that study.) The increase in glycerophosphocholine is suggestive of the increased rates of PtdCho degradation. It is possible that PtdCho degradation is catalyzed by PLA in Alzheimer's disease to a higher extent than by phospholipase D (PLD) (*see* below), hence an increase in glycerophosphocholine. Since PLA might be specific for a different pool of PtdCho (e.g., containing different fatty acids) than PLD, the net result might be a change in molecular species of PtdCho that might be pathogenic to membranes.

5. The activity of PLD (the enzyme that catalyzes the hydrolysis of PtdCho to free choline) and of CAT are decreased to a similar extent in autopsy specimens of cortexes of patients that died with Alzheimer's disease (Julian Kanfer, personal communication). It is tempting to speculate that PLD is specifically localized within cholinergic nerve terminals, and the decrease in its activity is a reflection of their degeneration; alternatively the decrease in PLD activity might reflect a general abnormality in phospholipid metabolism characteristic to Alzheimer's disease.

Since the discoveries of cholinergic deficits in Alzheimer's disease, several clinical studies have been performed that utilized various doses of choline or lecithin as possible therapeutic agents in the treatment of the disease (cf. Wurtman et al., 1984). The rationale for these clinical trials was that the choline (free or liberated from lecithin) would be used by the surviving cholinergic neurons as the precursor of ACh resulting in some restoration of the cholinergic tone in the brain. It is apparent that these procedures might also lead to increases of Ch-PL synthesis and therefore improve the functions of membranes that might be affected by "autocannibalism." Though these clinical trials have been mildly successful at best, it has to be stressed that people with symptoms of Alzheimer's disease probably suffer a cholinergic lesion so severe that it might be irreparable. The choline/lecithin supplementation regimens might be more useful in treating patients with smaller lesions, i.e., those who are at risk of getting the disease. Therefore it would be highly desirable to develop a diagnostic tool that would help identify such individuals so that they could be placed on lecithin treatments early in the course of their illness.

The Relationship Between Panic Disorder and Agoraphobia: An Epidemiologic Perspective

Myrna M. Weissman, Ph.D.,[1] Philip J. Leaf, Ph.D.,[1] Dan G. Blazer, M.D., Ph.D.,[2] Jeffrey H. Boyd, M.D., M.P.H.,[3] and Louis Florio, B.A.[1]

Introduction

This paper presents the most recent data on the epidemiology of panic disorder and agoraphobia based on findings from the Epidemiologic Catchment Area (ECA) Project, and examines the relationship between agoraphobia and panic disorder and symptoms in light of these epidemiologic data.

Studies of large population samples that include both treated and untreated persons, such as the ECA, are essential for obtaining a true estimate of the prevalance of a disorder and for understanding the complete clinical picture. Since, for many disorders, few ill persons seek medical treatment, those who do seek treatment may represent the more severely ill persons or persons with multiple disorders. The need for epidemiologic data is particularly true for the anxiety disorders where the presenting symptoms may be misconstrued as cardiac problems, as in panic disorder, and may never come to the attention of a psychiatrist, or where the presenting symptoms may include social withdrawal, as in agoraphobia, and may never lead the person to seek treatment.

Epidemiologic Studies Using RDC or DSM-III Criteria

Data on the epidemiology of panic disorder and agoraphobia based on Research Diagnostic Criteria (RDC) or DSM-III criteria are now available from four epidemiologic surveys: the 1975 New Haven Survey (Weissman et al., 1978); the 1979 National Survey of Psychotherapeutic Drug Use (Uhlenhuth et al., 1983); the Zurich Study (Angst & Dobler-Mikola, in press); and the ECA (Regier et al., 1984). The details of these findings have been presented elsewhere (Merikangas & Weissman, 1985; Weissman, 1985; Weissman et al., 1985). This report will focus on recent data from the NIMH ECA study.

The Epidemiologic Catchment Area Survey (ECA)

The ECA study, based on interviews with community samples of over 15,000 adults age 18 years and older, using the Diagnostic Interview Schedule (DIS), was independently conducted at five sites: New Haven, Connecticut (Yale University); Baltimore, Maryland (Johns Hopkins University); St. Louis, Missouri (Washington University); Piedmont area, North Carolina (Duke University); and Los Angeles, California (UCLA). Thus far, data have been published or presented for the first wave of interviews at Yale, Johns Hopkins, and Washington University (Boyd, 1985; Boyd et al., 1985; Myers et al., 1984; Robins et al., 1984; VonKorff et al., 1985). However, preliminary data are now available from all five sites. More comprehensive presentations of these data will be made in future reports. The full details of the design and methods of this survey are described elsewhere (Eaton & Kessler, 1985; Regier et al., 1984).

Results

Six-Month Prevalence Rates of Panic Disorder and Agoraphobia

There is reasonable consistency of findings in the 6-month prevalence rates/100 of panic disorder across the five ECA sites, where the range of rates is 0.6 to 1.0/100 (Table 1). At all sites (not shown here) the rates are higher in women than men.

There is greater variability between sites in the 6-month prevalence rates of agoraphobia (2.7 to 5.8/100). The rates are highest in Baltimore and Piedmont. At all sites (not shown here) the rates are higher in women than men.

TABLE 1. Six-Month Prevalence Rates/100 Panic Disorder and Agoraphobia: ECA.

	Panic Disorder	Agoraphobia
New Haven, CT	0.6	2.8
Baltimore, MD	1.0	5.8
St. Louis, MO	0.9	2.7
Piedmont, NC	0.7	5.4
Los Angeles, CA	0.9	3.2

Relationship Between Agoraphobia and Panic Disorder

There is good evidence from epidemiologic and clinical studies that more than one anxiety disorder tends to occur in individuals over their lifetime. In the 1975 New Haven survey, over 80 percent of persons with GAD had had at least one of the other anxiety disorders in their lifetime; 30 percent of persons with phobias had had panic disorder at some time in their life. There was also an overlap of the anxiety disorders with major depression: Over 7 percent of persons with GAD, 2 percent with panic disorder, and 4 percent with phobia had major depression at some time in their life (Weissman, 1985).

Similarly, on the basis of data from three ECA sites, Boyd et al. (1984) found that the odds of having a second anxiety disorder or a major depressive episode, given the presence of an anxiety disorder, were significantly and substantially increased. Angst and Dobler-Mikola (in press) also found a high overlap between the anxiety disorders. Longitudinal studies are necessary for understanding the relationship among the anxiety disorders and between anxiety and affective disorders.

Of particular interest has been the relationship between panic disorder and symptoms and agoraphobia. According to Klein's observations, agoraphobia is a conditioned reaction to the sudden onset of unexplained panic attacks—a view that has been adopted widely by many clinicians and researchers who rarely find patients who have agoraphobia without panic disorder or symptoms.

Agoraphobia With Panic Disorder or Symptoms—ECA

The lifetime rates of agoraphobia with and without panic disorder or symptoms were examined in the five-site ECA data (Table 2). The lifetime rates of agoraphobia with panic disorder or symptoms ranged from 1.7 to 2.6/100, and without panic disorder or symptoms ranged from 1.4 to 6.6/100 in the five sites. Thus a substantial portion of subjects in all five sites met the criteria of agoraphobia without panic disorder or symptoms ever.

TABLE 2. Lifetime Rates/100 Agoraphobia: ECA.

	With Panic Disorder or Symptoms	Without Panic Disorder or Symptoms
New Haven, CT	2.2	1.4
Baltimore, MD	2.6	6.6
St. Louis, MO	1.9	2.3
Piedmont, NC	2.0	5.8
Los Angeles, CA	1.7	3.1

In a closer examination, we found that at all five sites there were subjects with agoraphobia and some symptoms of panic who did not have the three attacks in 3 weeks as required to meet the diagnostic criteria for panic disorder.

Figure 1 shows the percent of subjects with agoraphobia plus panic disorder or symptoms, other psychiatric disorders, or no other disorder over a lifetime in the five ECA sites. The excess risk of agoraphobia in Piedmont and Baltimore is largely accounted for by the subjects with pure agoraphobia. The pure agoraphobics comprise nearly 44 percent of the agoraphobics in Baltimore and 53 percent in Piedmont, but only 23 percent in New Haven, 34 percent in St. Louis, and 37 percent in Los Angeles. The subjects with agoraphobia and panic disorder comprise the smallest percent of agoraphobics at all five sites (range 6 percent to 13 percent). The range of persons with agoraphobia who also have other disorders is 16.5 percent to 28.1 percent across the five sites. There was more variability between sites of subjects with agoraphobia and panic symptoms (50.4 percent in New Haven, 22.5 percent Baltimore, 32.4 percent St. Louis, 16.8 percent Piedmont, 28.0 percent Los Angeles).

A range of other psychiatric disorders (not shown here) occurred in subjects with agoraphobia and no panic disorder or symptoms. The most common diagnoses were depression and alcohol or drug abuse.

Conclusion

1) The 6-month prevalence rate of panic disorder is approximately 1 percent, which is consistent across the five sites. The rates are higher in women than men at all sites.

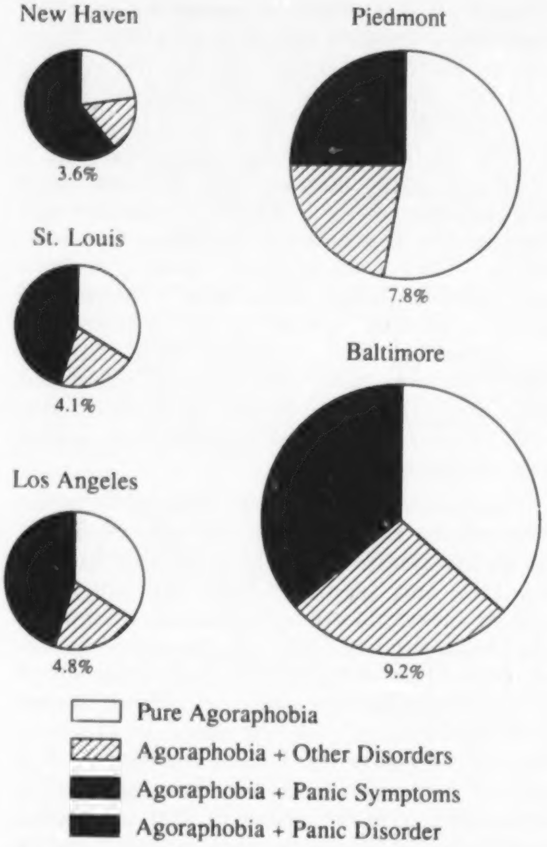

FIGURE 1. Percent of subjects with agoraphobia, with and without other disorders over a lifetime: ECA.

2) There is more variability between sites in the 6-month prevalence rates of agoraphobia. At all sites, the rates are higher in women than men; and the rates are higher than for panic disorder.

3) Agoraphobia is a heterogeneous disorder. The clinicians who want to revise the DSM-III to include agoraphobia as a variant of panic disorder from their perspective may be correct in that agoraphobia *usually* occurs with panic disorder or panic symptoms in clinical practice, especially in anxiety clinics.

Moreover, the patient with agoraphobia and panic symptoms is more likely to be motivated to come for the treatment of the distressing symptoms of panic, whereas the patient with only agoraphobia is more apt to stay home. Thus, from the clinician's perspective, agoraphobia is probably rarely seen without panic symptoms or disorder.

Boyd et al. (1985; in press) found that, when they divided agoraphobics into those who received and those who did not receive treatment by a mental health specialist in the last 6 months, at every ECA site a larger proportion of the treated agoraphobics have a history of panic attacks than did untreated agoraphobics. Only at Piedmont did this difference reach statistical significance, however. They concluded that treated agoraphobics more often have a history of panic attacks than do untreated agoraphobics. The epidemiologic studies, which include both treated and untreated cases, suggest that there may be several pathways to agoraphobia other than as an avoidance of panic.

The discrepancy between clinical observation and the ECA findings also may be inherent in the assessment of agoraphobia itself in the DIS and in the SADS. As noted by Spitzer (personal communication, December 18, 1985), the key DSM-III concept of agoraphobia—"fear of being in a place from which escape might be impossible or difficult in case of incapacitation"—is not asked in precisely that way in either the DIS or the SADS. The key concept in the DIS is "strong fear of something or some situation that is avoided even though there is no real danger," and in the SADS-L it is "usually the avoidance is recognizable as unreasonable. In some cases, however, subjects avoid situations because they anticipate overwhelming anxiety." These subtle differences in wording could account for some of the findings.

We are planning a follow-up study to clinically examine those subjects in the community who have agoraphobia without panic disorder or symptoms. It is possible that misdiagnosis has occurred. In addition to our clinical reappraisal, further study might include family studies as well as use of other available diagnostic assessments.

On the other hand, the ECA project raises questions as to the DSM-III criteria for agoraphobia. It may be that these criteria now designate as disordered a group of individuals meeting the criteria for agoraphobia but who experience no panic. Those agoraphobics seen in tertiary care settings may represent the most severely ill cases, or may be individuals entering treatment due to the panic attacks.

Acknowledgments

This research was supported in part by grant MH30929, the Yale Mental Health Clinical Research Center, National Institute of Mental Health; by the John D. and Catherine T. MacArthur Foundation Mental Health Research Network on Risk and Protective Factors in the Major Mental Disorders; and by the Epidemiologic Catchment Area (ECA) Program.

The Epidemiologic Catchment Area Program is a series of five epidemiologic research studies performed by independent research teams in collaboration with staff of the Division of Biometry and Epidemiology of the National Institute of Mental Health. The NIMH Principal Collaborators are Darrel A. Regier, Ben Z. Locke, and Jay Burke; the NIMH Project Officer is Carl A. Taube. The Principal Investigators and Co-Investigators from the five sites are: Yale University, U01 MH34224—Jerome K. Myers, Myrna M. Weissman, and Gary L. Tischler; Johns Hopkins University, U01 MH33870—Morton Kramer, Ernest Gruenberg, and Sam Shapiro; Washington University, St. Louis, U01 MH33883—Lee N. Robins and John Helzer; Duke University, U01 MH35386—Dan Blazer and Linda George; University of California, Los Angeles, U01 MH35865—Marvin Karno, Richard L. Hough, Javier I. Escobar, M. Audrey Burnam, and Dianne M. Timbers.

Recent Developments in the Understanding and Pharmacotherapy of Panic Attacks

Michael R. Liebowitz, M.D., Abby J. Fyer, M.D., Jack Gorman, M.D., and Donald F. Klein, M.D.[1]

Because of the prevalence and morbidity of panic disorder and agoraphobia with panic attacks, development of effective pharmacological treatment over the past two decades has been one of the important developments in modern psychiatry. The ramifications for clinical practice, diagnostic classification, and elucidation of pathophysiology have been vast.

With regard to treatment, pharmacotherapy has rendered panic attacks relatively easy to treat and agoraphobia with panic attacks much more amenable to treatment.

With regard to diagnostic classification, imipramine responsivity of panic attacks but not of anticipatory anxiety, and the reverse for standard benzodiazepines, suggested panic differed qualitatively rather than quantitatively from generalized anxiety. This substantially contributed to the subdivision of the DSM-II category of anxiety neurosis into panic disorder and generalized anxiety disorder, with most anxiety disorder patients who come for psychiatric treatment falling into the former category. Pharmacotherapy also demonstrated the importance of panic attacks as a core feature in most cases of agoraphobia.

With regard to pathophysiology, effective drug treatments suggest that panic attacks are neurochemically mediated, although important questions remain about what specific neurotransmitter systems are involved and to what degree cognitive factors are operative.

Below we review new findings, continued uncertainties regarding drug treatment, and models of how drugs might actually operate in panic disorder.

New Findings

The efficacy of imipramine in blocking panic attacks is well established in double blind placebo controlled studies (Klein, 1964; Zitrin, 1983), as is the antipanic efficacy of phenelzine (Sheehan et al., 1980). More recently, the triazolobenzodiazepine alprazolam has been shown to block panic attacks (Sheehan, 1984). In agoraphobia with panic attacks alprazolam definitely blocks the panic attack, although in our pilot study of 20 patients resolution of anticipatory anxiety and phobic avoidance sometimes accompanied and sometimes followed full panic blockade (Liebowitz et al., 1986). Curiously, in one open treatment study the nonresponders differed from responders in having higher baseline Hamilton Anxiety scores (Liebowitz et al., 1986).

Although never demonstrated by a controlled study, in our clinic desmethylimipramine (DMI) seems as effective as imipramine in blocking panic attacks, although somewhat higher doses appear to be needed. In one sample, mean effective daily antipanic dose for DMI was 271 mg as opposed to an effective antipanic dose of imipramine of 178 mg.

Several investigators have reported antipanic efficacy with clomipramine (CMI) in open clinical trials (Gloger et al., 1981; Caetano, 1985). Interestingly, effective CMI doses in 22 patients in one trial ranged from 10 to 50 mg/day with a mean of 26.4 mg, and several patients had initial exacerbations on 25 mg/day (Caetano, 1985). The investigator recommended that one begin with a 5 mg dose. Also, major panic attacks tended to be suppressed within 7 to 14 days of treatment. A limitation of this study was concomitant use of benzodiazepines, which were not

Supported in part by MH 903-1163C, MHCR 903-C006 and Research Scientist Development Award MH-00416 (Dr. Gorman) from the National Institute of Mental Health.

specified as to dose or type. Gloger et al. (1981) used up to 100 mg/day of CMI in an open trial of 8 patients with panic disorder and 12 agoraphobics; 75 percent of each group were reported asymptomatic after 8 weeks of treatment. Forty percent of the sample showed initial worsening on 25 mg/day of CMI, and required smaller starting doses. Forty-five percent of the sample required CMI doses of less than 50 mg/day for effective symptom control.

Gorman et al. (unpublished data) administered fluoxetine, a specific serotonin reuptake blocker, to 16 patients with panic disorder or agoraphobia with panic attacks in an open clinical trial. Patients dropped out of the clinical trial prematurely because of overstimulation or became panic-free with approximately equal frequency. A substantial number of panic patients apparently cannot tolerate fluoxetine 10 mg/day at least as initial therapy, and 2.5 and 5 mg initial doses need to be tried.

The serotonin precursor 5 hydroxytryptophan (5 HTP), in conjunction with carbidopa, has also been found in an open pilot study to be effective in blocking panic attacks, although, again, a certain percentage of patients showed overstimulation but were successfully treated with lower doses (Kahn & Westenberg, 1985). Zimelidine, another selective serotonin reuptake blocker, also appeared to block panic attacks in an open clinical trial of 13 patients (Koczkas et al., 1981). In this study, seven patients definitely improved while six discontinued treatment after 6 weeks because of poor health. This study involved patients with agoraphobia, social phobia, or mixed phobia, so it is impossible to assess the antipanic effect, especially since panic attacks themselves were not a dependent measure. Another limitation was the allowed concomitant use of oxazepam. Dizziness and dry mouth increased in the nonresponders.

There are anecdotal data that trazadone, another drug with relatively greater impact on serotonin than norepinephrine, is effective in panic patients. One open clinical series suggested that clonazepam, a high potency benzodiazepine that does not have a triozolo structure, is also effective in blocking panic attacks (Fontaine & Chouinard, 1984). Interestingly, in addition to its effect on the benzodiazepine-GABA receptor complex, clonazepam has also been reported to increase both serotonin synthesis and function in man at normal clinical doses (Chouinard, 1985).

Finally, Sheehan has reported that phenelzine is somewhat more potent than imipramine or alprazolam in blocking panic attacks and reducing related anticipatory anxiety and phobic avoidance. There are no published studies of monoamine oxidase inhibitors (MAOI) other than phenelzine in panic patients. We have treated three panic patients with the MAO B inhibitor deprenyl up to 40 mg/day and one has shown an antipanic effect, which is inconclusive.

Uncertainties

The relapse rate after tapering drug treatment for panic patients is uncertain. In a report of several hundred mixed phobic patients treated openly with phenelzine, Kelly et al. (1970) found that 30 percent of the patients who were well for 1 year were able to come off medication and remain well, although the length of follow-up is not specified. Another 30 percent relapsed after attempting to reduce or stop the MAOI, while 34 percent were advised not to try drug withdrawal.

Zitrin and Klein (1983) found a relapse rate from 19 to 31 percent in agoraphobic patients treated for 6 months with imipramine and supportive or behavioral therapy who showed at least moderate improvement, and were then followed for 2 years. Relapse in this study was defined as a return of avoidance behavior. There were no significant differences in relapse between supportive or behavioral therapy. Sheehan (personal communication, 1985), however, reports relapse rates of over 70 percent after stopping imipramine, phenelzine, or alprazolam. Relapse in this series was defined as any return of unexpected anxiety episodes or avoidance such that the patient requested to restart medication on two separate occasions.

Criteria for relapse are not the same in the Zitrin-Klein and Sheehan studies. One variable is whether you are talking about one or two panic attacks when patients come off drug or a full relapse. This may be a crucial point in terms of withdrawing panic patients from alprazolam, which may be more problematic than discontinuing imipramine or phenelzine in terms of withdrawal symptoms and return of panic attacks. There is some suggestion, however, that even if patients have panic attacks coming off alprazolam, if they can continue for several weeks off the drug, this may disappear.

While there are substantial data showing the efficacy of behavioral treatment approaches such as exposure on agoraphobic symptoms of avoidance, the efficacy of behavior therapy for the actual panic attack has received little study. Beck (1985) has hypothesized that a panic attack represents a cognitive reaction of great alarm to a benign physical disturbance. He gives as an example somebody standing up, feeling lightheaded and then feeling very distressed that something terrible might be happening, or a skier with a history of a heart attack having rapid heart beat from exertion and reacting with great alarm when he thought he might be having another heart attack. These are not, however, representative of the kinds of patients seen in anxiety research programs. Here patients complain that their initial panic attacks consist of dramatic physical disturbances involving racing heart, shortness of breath, dizziness, etc. preceded by, accompanied by, or immediately followed by panicky feelings that they are about to die, lose control, or pass out.

Nevertheless, it is possible to conceptualize that panic attacks do consist of some kind of profound physical arousal to which patients then react with profound emotional disturbance because they think this physical arousal means something terrible is happening and they are in grave danger. The anxious thoughts may exacerbate the physical symptoms and vice versa in a positive feedback loop until panic sets in. This is a two-component hypothesis as opposed to a one-component hypothesis where the physical- and mental-emotional symptoms are part of a single, biologically based arousal process. In the two-component process the cognitive reaction is usually seen as an overreaction conditioned by some previous experience, although it could be a "hardwired" alarm reaction to sensations normally associated with real danger to the organism.

A two-component hypothesis provides a rationale for cognitive-behavioral therapy, which attempts to have patients learn to relabel their physical arousal, changing it from "something terrible must be happening" to "there goes my heart again" or "there goes my dizzy symptom again," etc. They would still have physical disturbances but no longer react with fear that escalates into terror, turning a panic attack into a symptom attack. The efficacy of this approach is only now, however, receiving systematic study, although anecdotal data suggest benefit in some panic patients. There are several open clinical reports that training in slow breathing can lower frequency and lessen intensity of panic attacks in subsets of panic patients (Bonn et al., 1984; Rapee, 1985; Clark et al., 1985), perhaps by preventing secondary emotional escalation and hyperventilation.

Models of How Drugs Work

There are several types of data that need to be taken into account.

1) Effective pharmacotherapy blocks lactate-induced as well as clinical panics. A reasonable formulation is that clinical panic attacks involve discharge of specific centrally mediated neurophysiological circuits, and that effective antipanic drugs raise the threshold for firing of these circuits. This is true while the drugs are being taken and, for many patients, for months to years after drug therapy is stopped. If drugs simply blocked nonspecific physical arousals that, in turn, provoked cognitive overreactions, then lactate-induced arousal should not be blocked unless antipanic drugs also blocked the physical effects of lactate, which they do not appear to do. Antipanic drugs could hypothetically also block cognitively mediated panic responses to any stimulus, but in practice do not do so.

2) Certain cognitive behavioral procedures, while not totally suppressing all vestiges of panic attacks, are anecdotally reported to alter their characteristics. Untreated, most panic patients report at least occasional episodes where they feel profound autonomic arousal plus the experience of being about to

die, lose control, or pass out. If cognitive-behaviorally treated patients can prevent themselves from reaching the extremes of panic while continuing to experience mild to moderate or even severe degrees of autonomic arousal (palpitations, lightheadedness, etc.), it would suggest that this physical arousal is the core of panic attacks, with the extreme of terror and/or hyperventilation as secondary, cognitively mediated reactions. Controlled studies are now needed to see what aspects of panic attacks can be treated by cognitive and behavior therapies. It has already been demonstrated that drug therapy can suppress the physical and emotional aspects of panic, but leave the patient initially with high anticipatory anxiety as he or she still feels helpless and vulnerable should an attack occur.

One would predict that if successful in ameliorating panic attacks, cognitive-behavioral therapy would produce more steep declines in anticipatory anxiety than in physical accompaniments of panic (the reverse of drug therapy) because the fear of what to do when an attack starts is directly addressed via new cognitive and/or breathing techniques. With drug therapy no coping tools are provided, so anticipatory anxiety can only extinguish with time, while the actual somatic manifestations of a panic attack are directly blocked.

3) Some patients manifest lactate sensitivity in the face of being clinically well (Fyer et al., 1985). We have 10 patients who panicked with lactate, were successfully treated with drug therapy, remained panic free after drug withdrawal, and were rechallenged with lactate 1 to 6 months off medication. Six of them panicked with lactate, but remained clinically well for at least 6 months after that. Here one has to assume that the threshhold for discharge of relevent CNS systems remains sufficiently high to prevent spontaneous triggering of panics, but not high enough to be refractory to lactate challenge. In normals, the threshold for firing of the relevant systems is sufficiently high to be refractory to spontaneous discharge and lactate activation, at least with 0.5 molar DL-lactate. Higher doses of lactate, however, have not been tested in normals.

If our conjectures about panic are correct, then we should include as (for now, separate) types of clinical and laboratory-induced panic certain patterns of distressing physical symptoms with abrupt onset that are not accompanied by profound emotional arousal. Supporting this view is our finding that patients with clinical panics who do not panic with lactate still look physiologically and clinically different during the infusion than normal controls, suggesting some added or pathological arousal from the lactate that does not go on to meet *current* criteria for a *panic attack* (Liebowitz et al., 1985). These lactate nonpanickers may be showing a somatic response to lactate that reflects their neurochemical vulnerability, but not of sufficient magnitude in that particular setting to set off significant emotional anxiety.

If specific patterns of somatic arousal are the biological core of panic, this could explain the difference between panic and generalized anxiety. Generalized anxiety may be an overreaction to nonspecific internal or external events, while panic is one or more centrally mediated specific pattern of somatic arousal with variable emotional responses.

The final issue is the neurochemical nature of panic vulnerability, be it somatic arousal with cognitive overreaction or a unitary physical-emotional arousal process. Adrenergic systems have received the most attention, initially suggested by Redmond's work (1979) with locus ceruleus stimulation and blockade in primates. As discussed earlier, however, drugs that enhance the effects of serotonin appear both active as antipanic agents and overly stimulatory if given in initially too high doses, a set of findings that has received little attention. Lingjaerde (1985) has recently reported that lactate facilitates serotonin uptake in platelets and suggests comparable effects in the CNS. Serotonergic stimulation and blockade studies are therefore indicated for panic patients, since serotonergic systems, acting independently or via effects on noradrenergic or other systems, may be involved in the pathophysiology of panic attacks.

Possible Respiratory Abnormalities in Panic Disorder

Jack M. Gorman, M.D.,[1] Michael R. Liebowitz, M.D.,[1] Abby J. Fyer, M.D.,[1] Minna R. Fyer, M.D.,[1] and Donald F. Klein, M.D.[1]

Some abnormality in respiratory physiology has been hinted at as the cause of panic attacks for decades. One school of thought sees hyperventilation as the cause of panic attacks. Retraining the subject to breathe abdominally instead of thoracically is held to be curative (Lum, 1981).

Because little scientific rigor has been attached to the investigation of these claims, they have understandably been met with considerable skepticism in the psychiatric community. The prevailing opinion has been that hyperventilation is one of the many manifestations of a panic attack, no different from tachycardia, trembling, or sweating (Missri & Alexander, 1978).

Recent work, however, has again placed hyperventilation into a key role in the pathogenesis of panic. While it still appears simplistic to insist that hyperventilation alone is the root cause of panic disorder, it is becoming increasingly clear that disordered ventilatory responses, and the consequent alterations in acid-base physiology, are indeed etiologically important.

Are Panic Disorder Patients Chronic Hyperventilators?

Several experiments have shown that patients with broadly defined anxiety disorder breathe faster and more deeply, with more frequent sighs, than normal controls at rest (Tucker, 1963; Huey & West, 1983). These have been taken to mean that patients with anxiety disorder are chronic hyperventilators.

There are several problems with such an interpretation. First, and most obvious, we now know that lumping patients with "anxiety disorder" into one general category only serves to blur physiological findings and obscure possible diagnostically related markers. Second, an increased minute ventilation could be the product of acute stress, merely reflecting (in anxious patients) a greater cognitive reaction to being part of an experiment. Finally, increased minute ventilation does not necessarily reflect hyperventilation. Hyperventilation refers to ventilation in excess of cellular metabolic demands. The anxious patients could be hypermetabolic compared to the normal controls.

True hyperventilation quickly—that is, within seconds—produces a reduction in the arterial concentration of carbon dioxide (CO_2), known as hypocapnia. This in turn causes respiratory alkalosis, defined as a pH exceeding 7.45. Hypocapnia is a potent stimulator to vasoconstriction. With sufficient hyperventilation the subject will feel faint, confused, nauseated, dizzy, and anxious. Heart rate increases and the subject feels dyspneic, even though the reverse is actually the problem.

With chronic hyperventilation, two additional physiological changes take place. First, the kidney attempts to compensate for alkalosis by excreting additional bicarbonate and retaining titratable acid (Stanbury & Thomson, 1952). Second, the constriction of cerebral vessels leads to cellular hypoxia which stimulates dilatation (Plum et al., 1968). The chronic hyperventilator will have nearly normal pH, low PCO_2, low bicarbonate, and normal vascular caliber. Both acute and chronic hyperventilation cause hypophosphatemia (Mostellar & Tuttle, 1964) by complex and incompletely understood mechanisms.

This work was supported in part by National Institute of Mental Health grants MH-37592 and MH-30906, and by a Research Scientist Development Award, MH-00416, to Dr. Gorman.

We were surprised to find, in the course of analyzing data from our sodium lactate infusion experiments of patients with panic disorder, evidence of chronic, rather than acute, hyperventilation (Liebowitz et al., 1985). That is, in the 30-minute period of baseline measurement before we started the infusion, the patients with panic disorder had lower PCO_2 and lower bicarbonate, but not higher pH, than normal controls. Had the patients merely been reacting to the stress of being in the laboratory or the anticipation of getting lactate, we would have expected acute hyperventilation and alkalosis. This was not found.

In a subsequent analysis with larger sample size (Gorman et al., in press) we again observed chronic hyperventilation in panic disorder. In addition, we now show that acute hyperventilation is superimposed on chronic hyperventilation, so that at the point of a lactate-induced attack the patient drops the PCO_2 even further. Finally, in a *post hoc* analysis, an inorganic phosphate level lower than 2.25 mg/dl just prior to starting lactate appeared to assure that the patient would go on to have lactate-induced panic.

These findings are precisely what the hyperventilation theorists would have predicted. Specifically, the chronic hyperventilator, when stressed, appears to hyperventilate even more and quickly throw him or herself into respiratory alkalosis. This, plus the cerebral arterial constriction, could account for the symptoms of a panic attack. In addition, hypophosphatemia itself can cause neurologic symptoms including anxiety and paresthesias (Kreisberg, 1977). The fact that panic disorder patients do not appear to be hyperventilating when seen outside the laboratory is not a problem for this theory; several studies have shown that once the chronic hyperventilatory pattern of blood gas changes has been established, only a few deep breaths every hour are sufficient to maintain it (Salzman et al., 1963).

Does Treatment Cure Hyperventilation?

Of course, there are abundant claims, mostly anecdotal, that behavioral treatment aimed at stopping hyperventilation also cures panic attacks. But if hyperventilation is truly involved in the etiology of panic, then any treatment that blocks the attack should also eliminate the biological evidence of chronic hyperventilation.

Here, we have some suggestive evidence. First, we restudied a group of 20 panic-disorder patients after they had been panic-free by virtue of anti-panic medication for at least 4 weeks (Gorman et al., 1985). What we observed was a normalization of venous pH, PCO_2, and bicarbonate. That is, the variance of these measures was greater in the patients before treatment than controls, but after treatment the patient variance equalled that of the controls. In other words, pH, PCO_2, and bicarbonate became normal after treatment, although in a few cases this meant pH rising to normal and PCO_2 declining to normal.

The variance may be accounted for by our recent observation that patients with panic disorder and mitral-valve prolapse have higher PCO_2 than patients with panic disorder without mitral-valve prolapse (unpublished data). This suggests that not all patients with panic disorder are chronic hyperventilators: perhaps patients with prolapse are a different subgroup with autonomic abnormalities other than respiratory.

Another way to look at the treatment issue with respect to hyperventilation is to see what symptoms patients complain of before and after panic blockade is achieved.

Patients who do not panic during lactate infusion still experience greater symptomatic discomfort than controls. This is measured by a 17-item checklist called the Acute Panic Inventory (API). We compared items on the API among three groups: controls receiving lactate infusion, patients receiving lactate infusion for the first time while still ill but not experiencing a lactate-induced panic attack (NP1), and patients receiving a second lactate infusion after panic blockade by anti-panic medication and again not experiencing a lactate-induced panic (NP2). The API was administered three times to each subject during each infusion.

A drug responsive API-item should have the following four characteristics by analysis of variance for repeated measures (ANOVAR):

1) The item should show a time effect within the infusion, with increasing severity.

2) The item slope over time should be greater for the NP1 group than the NP2 group.

3) The item slope over time should be greater for the NP1 group than controls.

4) The item should be equal between NP2 and controls, thereby showing normalization with drug.

We would be interested in whether there is a group by time interaction indicating that the slope of the increment in symptomatology for a given item in the NP1 group exceeds the slopes in both the control and NP2 groups. This would indicate that the NP1 group, that is the unmedicated patients, were responding to lactate infusion in a qualitatively unique way.

Only one group of items each met these criteria: feeling faint, difficulty breathing, feeling dizzy, feeling confused, derealization, difficulty concentrating, and twitching. These are all symptoms characteristic of hyperventilation. The other items are fear of dying, general fear, palpitations, urge to urinate, urge to defecate, depersonalization, sweating, difficulty speaking, and feeling nauseated.

Hence, we can conclude that it is precisely those items that reflect hyperventilation that are both highly reactive to lactate infusion and normalized by anti-panic medication.

Can Hyperventilation Acutely Provoke Panic?

Can enforced hyperventilation in a patient with panic disorder actually provoke panic? The standard laboratory provocation of panic is the lactate infusion. Other groups claim to provoke attacks with a variety of other agents, including yohimbine, isoproterenol, norepinephrine, and caffeine. But could something as simple as asking the patient to breathe hard be equally effective?

Here, the literature is misleading. There are many references to a "hyperventilation test" as if it were a clinically accepted procedure. No one had seemingly bothered to test its usefulness. Patients supposedly had attacks during room air hyperventilation (RAH). But were these attacks due to the actual induction of respiratory alkalosis or merely to the fatigue and discomfort of breathing fast? Also, how was the obvious demand on the subject to present some symptoms controlled for?

What was needed was a control for hyperventilation in which the subject must breathe fast without becoming hypocapnic or alkalotic. This can be accomplished by the inhalation of 5 percent CO_2 in room air. Five-percent CO_2 inhalation triples minute ventilation but, because carbon dioxide is constantly being added, no hypocapnia develops. We felt this would be a good control for RAH.

Our results were unexpected (Gorman et al., 1984). Seven of the first 12 patients with panic disorder had attacks during the 5-percent CO_2 inhalation phase. Only three had attacks during RAH. Controls were sensitive to neither CO_2 nor RAH.

We subsequently learned that Cohen had performed a similar experiment on patients with "neurocirculatory asthenia" almost 30 years ago and obtained the same result (Cohen & White, 1950). Another group has since replicated our findings (Woods et al., 1981).

One of the things that CO_2 does is to stimulate locus ceruleus discharge (Elam et al., 1981). One speculation was, therefore, that CO_2 was panicogenic because it induced an increase in central noradrenergic discharge.

It is also the case that lactate is quickly metabolized to bicarbonate and then to carbon dioxide. How quickly and to what degree lactate actually crosses the blood-brain barrier is controversial (Nemato et al., 1974). Bicarbonate does not cross readily at all (Pierce et al., 1971). Hence, lactate panic might actually be caused by an increase in central CO_2 concentration.

We have now extended our RAH-CO_2 protocol. The results are basically the same. To date, 12 of 31 patients with panic disorder have had acute panic attacks during a 20-minute inhalation of 5-percent CO_2. The CO_2 panickers have a faster rate of increase than nonpanicking patients or controls in almost every ventilatory measure: respiratory rate, tidal volume, minute ventilation, duty cycle, and inspiratory flow. They also have greater increases in diastolic blood pressure and plasma norepinephrine. However, no differences were found for plasma cortisol, systolic blood pressure, or plasma epinephrine. This is also the case for lactate-induced panic. Neither normal controls nor patients with other anxiety disorders (social phobia, obsessive compulsive disorder, and generalized anxiety disorder) were sensitive to 5-percent CO_2.

We have raised the "dose" of CO_2 in a few trials. Now, the rate of panic in patients with panic disorder increases to six of nine subjects, but three of three social phobics also panicked. Normal controls remain insensitive. At the 7-percent level, therefore, it is possible that sensitivity is enhanced but specificity sacrificed. This clearly needs further study.

Our rate of panic to RAH has increased somewhat to 7 of 30 subjects. Very few biologic changes characterize these RAH-induced attacks, however, and the change in API score is generally less than that seen for CO_2 panickers. In fact, two of the seven RAH panickers did not even become alkalotic because they stopped overbreathing too quickly. Hence, it remains possible that hyperventilation panic reflects a peculiar vulnerability to fatigue rather than the effects of alkalosis.

One other striking finding was that in the period following both CO_2 and RAH-induced panic attacks, the patient continues to hyperventilate. The normal response to the cessation of hyperventilation is virtual breath holding to allow CO_2 levels to rise to normal. But those patients who had panicked while hyperventilating continue to hyperventilate after being told to stop.

Van den Hout and Griez (1985) have done a number of experiments with CO_2 inhalation. They believe that "CO_2-induced" symptomatology does not occur until immediately after CO_2 is actually stopped. The method of CO_2 administration is simpler than ours: a double breath inhalation via face mask of a combination of 35-percent CO_2 and 65-percent oxygen (O_2). This procedure can be administered in a matter of minutes.

We have now used the Griez and van den Hout method in a few trials. Five of eight patients with panic disorder had attacks immediately following inhalation of 35-percent CO_2/65-percent O_2. Two additional patients felt in a "pre-panic" state. Only one of the eight had no increase in anxiety. By comparison, there were no attacks in five normal controls; only one complained of increased anxiety. The patients found the attacks very similar to their spontaneous attacks, although shorter in duration.

How do we account for the fact that patients with panic disorder appear to be chronic hyperventilators, yet panic when administered carbon dioxide? One possibility is that panic-disorder patients have a hypersensitivity to CO_2. This could conceivably involve the peripheral arterial chemoreceptors (carotid bodies and aortic bodies), intrapulmonary receptors, or the medullary chemoreceptors. Relatively low concentrations of CO_2 would trigger these centers to induce hyperventilation and other autonomic changes. Overwhelming the system with CO_2 produces such autonomic unrest that panic is provoked.

In order to avoid triggering these hypersensitive receptors, patients with panic disorder chronically hyperventilate, thereby maintaining CO_2 concentration as low as possible. Medications that block panic may work directly on the hypersensitive chemoreceptors to normalize their reactions. This would obviate the need for hyperventilation as an adaptive response. While hyperventilation is not the cause of panic according to this theory, abnormal respiratory physiology assumes a place of critical importance.

Behavioral Conception and Treatment of Panic

David H. Barlow, Ph.D.[1]

Behavior therapy "cut its teeth" on phobias. Since Wolpe's (1958) pioneering book on the treatment of neurotic problems a variety of behavioral procedures have been tested and proven effective in the treatment of phobia. During the 1960's and 1970's scores of studies were performed isolating the effective ingredients of these treatments. The overriding conclusion that emerged from this systematic research during the 1970's was that one particular procedure was common to all successful behavioral treatments for phobia (Mavissakalian & Barlow, 1981). This procedure, which came to be called exposure, consisted of motivating the patient to expose him or herself to a series of increasingly more difficult situations that provided the context for the phobic reactions and arranging conditions to facilitate this exposure. At present there are many psychologically based theories as to why this treatment is successful, including but not limited to extinction, habituation, emotional processing, and increases in perceived self-efficacy (Barlow & Mavissakalian, 1981; Barlow, in press). While none of these theories is fully supported as yet, there is clear evidence that exposure-based treatments are effective with phobias in general and agoraphobia with panic in particular. Some of these data are represented in Table 1 which summarizes the results of 24 controlled outcome studies testing exposure-based treatments for agoraphobia as reviewed by Jannson and Ost (1982). The data summarized in this review indicate that 70 percent of patients improved substantially with exposure-based treatments. The dropout rate averages 12 percent, although it is consistently higher for the type of exposure program which is administered in a very intensive fashion, for example, over a 2-week period, and much lower for programs administered in a more gradual self-paced manner (e.g., Barlow, O'Brien, & Last, 1984).

At the same time this systematic research was ongoing, research from another perspective was isolating the phenomenon of panic. In 1959 when agoraphobics were still called schizophrenics by most clinicians because of their severe symptoms and marked social impairment, Donald Klein had a clinical hunch regarding the importance of panic. From this idea emerged a progression of descriptive and pharmacological research identifying panic as a central component in many of the anxiety disorders. This, in turn, led to revisions in the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-III*) designating panic disorder as a separate diagnostic entity (American Psychiatic Association, 1980). Now the evidence is strong from both pharmacological and behavioral investigators that agoraphobias with panic and panic disorder do not differ in any substantial manner with the exception of the development of avoidance behavior as a complication in some, but not in all, people who initially suffer from unexpected panic attacks (Barlow, 1986).

If panic is indeed the central feature of agoraphobia, two questions arise. Why are exposure-based treatments as successful as they are, and what happens to panic attacks during exposure? Because of a somewhat different conceptualization of this disorder, behavior therapists very seldom measured panic in past studies, although clinical reports would indicate that panic attacks did indeed

decrease during successful exposure-based treatments. Nevertheless, more recently, clinical researchers investigating exposure-based treatments have measured panic more systematically, and the results are somewhat surprising. For example, Chambless, Goldstein, Gallager et al. (in press) assessed panic and avoidance behavior in a series of 35 patients receiving exposure-based treatments who were medication free at all times. They chose patients from a larger series who were medication free in order to observe more systemically the effects of exposure on panic. While this was not a controlled experimental study, the results, which are presented in Table 2, indicate that almost two-thirds of these 35 patients were free of panic attacks for at least a 1-week period at the 6-month follow-up. In fact, the results with panic seem to be somewhat better than the results for avoidance behavior where only 29 percent of the patients were free of avoidance. However, avoidance behavior was measured by a very conservative questionnaire which probably overestimates phobic avoidance. In any case, it seems that exposure-based treatments are consistently effective in reducing panic attack when this is measured, and that this is a very important result in exposure-based treatments. For example, Barlow et al. (1984), in a study examining the effectiveness of adding the spouse to exposure-based treatments, discovered that among those who responded to the treatment, significant reductions occurred in a composite measure of panic combining frequency, duration, and intensity of attacks. But for those who were judged to be nonresponders on a broadly based criteria, this measure of panic actually showed increases. One-third of the responders in this study reported no panic attacks whatsoever after treatment. These results are presented in Table 3. These results have now been replicated in several other studies examining exposure-based treatments (Michelson, Mavissakalian, & Marchione, 1985; Ghosh & Marks, in press).

Why do exposure-based treatments result in improvements in panic? To explain this one has to combine one old idea and one relatively new idea into a behavioral conceptualization of panic. This conceptualization leads to new behavioral treatments directed specifically at panic attacks which are in an early stage of development.

TABLE 2. Outcome of Behavioral Treatment of Agoraphobia on Avoidance and Panic for 35 Medication Free Patients at 6 Months.

Panic Attacks		Avoidance While Alone (as compared to normals)	
Yes	No	Yes	No
36%	64%	71%	29%

Retrospective survey evidence strongly suggests that the first unexpected panic occurs in the context of some marked life stress (Roth, 1960; Doctor, 1982; Last, Barlow, & O'Brien, 1984). It now seems that the occurrence of panic attacks in the population is far more widespread then we expected. For example, Norton (1985) found that almost 35 percent of the population reported one or more panics in the past year as indicated in Table 4. Norton has now substantiated these data in a replication study and other data from around the world are beginning to appear supporting this finding (Klerman, 1985).

If this is true, then one fascinating question concerns the differences between nonclinical people having occasional unexpected panics vs. those who end up in clinics seeking help for this problem. This latter group seems to comprise less than 5 percent of the population (Myers, Weissman, Tischler, et al., 1984). One possibility is that the latter group learns to fear the possibility of having another panic attack, a condition which seems to be present in almost all patients with panic disorder presenting at a clinic (Barlow, Vermilyea, Blanchard, et al., 1985). That is, some learning takes place in that the recent

panicker acquires an extreme sensitivity to somatic events because of the marked fear that panic may reoccur. The occurrence of slight physiological sensations, even if for perfectly normal reasons, may then evoke marked fear in the patient. This fear activates the autonomic nervous system and increases the intensity of somatic sensations resulting in an increasing spiral of fear with panic at the top of the spiral. The marked fear concerning the possibility of having another panic attack seems particularly likely to develop when no ready explanation or cause is available to which to attribute the initial panic attack. Thus, patients develop a "phobia" of internal physical sensations that may represent the beginnings of another panic attack. This phobia increases anticipatory anxiety, as well as a variety of somatic events, which, paradoxically, insure that future panic attacks will occur in an ever-spiralling pattern. The behavioral conception of panic, then, involves a psychobiological process wherein persons susceptible to anxiety experience an initial panic attack while under stress and subsequently develop a fear of certain patterns of somatic sensations that might represent the beginnings of another panic through a process called interoceptive conditioning. The four steps involved in this process, whether in the laboratory or in the natural environment are presented below.

1. The elicitation of physiological sensations.

2. The strength of the subjects' previously learned association between physiological sensations and psychological feelings of acute anxiety.

3. The degree of current (baseline) anxiety.

4. The degree of anxiety elicited by the experimental setting.

This, in fact, is the old idea referred to above since this pathway to panic was first published in 1964 (Breggin, 1964) as what was considered the best explanation for a long series of panic provocation studies in the laboratory using epinephrine.

Furthermore, this conceptualization of panic is very different from the "nonspecific stress" hypothesis often mentioned as a cause of laboratory panic. Interoceptive conditioning suggests that patients become acutely sensitized to specific patterns of internal physiological responses rather than to generalized arousal, and this seems to be well-illustrated in a very early study where panic was experimentally provoked in the laboratory (Lindemann & Finesinger, 1938). In this study 20 patients were administered either adrenaline or mecholyl, a parasympathetic stimulant with a very different pattern of physiological activation in a counterbalanced fashion. This was an extremely well-done study for the time. For example, verbatim accounts of panic attacks are provided which should convince even the most skeptical critic that what was being studied in 1938 was the same phenomenon of panic with which we are dealing today. Six of the patients panicked during adrenaline but not during mecholyl. Five panicked during mecholyl but not during adrenaline. Five panicked both during mecholyl and adrenaline, while four panicked under neither condition. Although studies such as these will have to be replicated using more current methodology, the results indicate that patients seem to learn to fear specific patterns of physiological responses.

Based on this conceptualization, new behavioral methods for treating panic directly have been devised in our center and elsewhere. What these methods have in common is that the important cues for exposure in patients with panic are not external cues found in shopping malls or any location away from a safe place or person, but rather the interoceptive cues that they have come to fear. Treatment then revolves around reproducing the physiological sensations that are most feared by individual patients in order to produce extinction or emotional processing of fear cues. Types of procedures that should be effective in this regard are listed in Table 5 and preliminary evidence exists for the effectiveness of some of them (Barlow, Cohen, Waddell, et al., 1984; Waddell, Barlow, & O'Brien, 1984; Clark, Salkovskis, & Chalkley, 1985; Orwin, 1973; Beck & Emory, 1985). In our clinic, for example, we assess for patterns of fear by having patients engage in a variety of exercises designed to produce different patterns of physiological symptoms. To activate cardiovascular symptoms we use exercise. For respiratory symptoms we induce voluntary hyperventilation. For audiovestibular systems we induce dizziness. When feared patterns are identified, these become part of treatment. Clark et al. (1985) treated 18 patients identified as sensitive to the effects of hyperventilation. Eleven were agoraphobic while seven were panicking without avoidance behavior. Panics were essentially eliminated in all patients as represented in Figure 1 through repeated exposure to the effects of hyperventilation combined with other behavioral procedures. Barlow et al. (1984) treated patients with panic disorder in a small controlled pilot study and found significant reductions on panic compared to the control group. Paradoxically, some of the effectiveness of exposure with panic may result from repeated evocation of panic in a benign context with resulting extinction or cognitive reappraisal of the consequences of panic.

Nonbenzodiazepine Anxiolytics: Insights Into Possible Mechanisms of Action

Cam P. VanderMaelen, Ph.D.,[1,2] Duncan P. Taylor, Ph.D.,[1] Greta Gehlbach, M.S.,[1] and Michael S. Eison, Ph.D.[1]

A wide variety of drugs have been used over the years in the treatment of anxiety; these include the opiates, alcohol, barbiturates, meprobamate, dopaminergic agents, various sedatives, and the benzodiazepines (BZs). The BZs were introduced 26 years ago and constituted a major advance in the treatment of anxiety; they are widely prescribed and are extremely effective for this indication. The pharmacology of BZs is well known; besides being effective in the treatment of anxiety, these compounds are also muscle relaxants, anticonvulsants, and sedative-hypnotics. Unfortunately, they interact with alcohol and other CNS depressants, such as the barbiturates, to produce potentially lethal effects. Benzodiazepines are sometimes abused, the potential for the development of dependence exists, and withdrawal symptoms sometimes occur upon cessation of benzodiazepine treatment (Lader, 1984). Because of these undesirable and unwanted effects of BZs, the search has continued for agents which would be more selective in the treatment of anxiety. As a result, a number of compounds have been synthesized in recent years which have demonstrated a pharmacological profile that has been termed "anxioselective" (Taylor et al., 1980).

One approach in the search for anxioselective drugs has been to modify the basic BZ structure in hopes of retaining anti-anxiety properties while eliminating unwanted ancillary effects. This effort has produced several candidates including Ro 16–6028 and Ro 17–1812, which appear to function as partial agonists at the BZ receptor. Neither of these two BZs, however, has proven to be sufficiently advantageous to warrant further clinical development (Merz, 1984).

Another approach to developing more anxioselective drugs has been to abandon the BZ structure altogether. This has resulted in the synthesis of a number of nonBZ compounds with clinical or preclinical indications of anxiolytic activity. However, it is important to point out that while these compounds are "nonBZ" from a chemical standpoint, not all of them are "nonBZ" from a pharmacological, mechanistic, or clinical standpoint. Indeed, some of these nonBZ anxiolytic compounds bind to the BZ receptor or to allosteric sites elsewhere on the GABA-BZ-chloride (GABA-BZ-Cl^-) ionophore complex (Williams, 1983).

[2] To whom correspondence should be addressed.

Thus, these nonBZ anxiolytics and putative anxiolytics may be categorized into two groups (Table 1). In Group 1 are included nonBZ compounds which bind to the GABA-BZ-Cl^- ionophore complex in some fashion. Group 2 compounds are those nonBZ compounds which do not bind to the GABA-BZ-Cl^- ionophore complex.

The Group 1 compounds can be further differentiated into subgroup. Subgroup A compounds are nonBZs which do, in fact, bind directly to the BZ receptor in much the same way that the BZs do. In subgroup B are nonBZs which bind to allosteric sites elsewhere on the GABA-BZ-Cl^- ionophore complex (Williams, 1983). In either case A or B, it is likely that the Group 1 compounds derive their associated anxiolytic activities by a mechanism similar or identical to that of the BZs: by potentiating GABAergic neurotransmission in the brain (Bowery, 1984). For example, zopiclone and suriclone are compounds in Group A which bind to BZ sites. They share most of the pharmacologic properties of the BZs in preclinical studies.

TABLE 1. New Nonbenzodiazepine Anxiolytics

Group 1: Agents which bind to the GABA-BZ-Cl^- ionophore complex.
    A. Agents which bind directly to benzodiazepine sites.
        1. Triazolopyridazines (CL 218,872)
        2. Cyclopyrrolones (zopiclone, suriclone, suproclone)
        3. Phenylquinolines (PK 8165, PK 9084)
        4. Pyrazoloquinolines (CGS 9895, CGS 9896)
        5. β-Carbolines
    B. Agents which bind elsewhere (to "allosteric" sites) on the complex.
        1. Barbiturates
        2. Pyrazolopyridines (tracazolate)
Group 2: Agents which do not bind to the GABA-BZ-Cl^- ionophore complex.
    1. Thiazolopyridines (ritanserin)
    2. Arylpiperazines (buspirone, gepirone, TVX Q 7821)

On the other hand, PK 8165, CGS 9896, and CL 218,872 display more anxioselective preclinical profiles and appear to achieve anticonflict activity in animals by acting selectively at subtypes of the BZ receptor (Petrack & Yokoyama, 1985). Subgroup B compounds include the pyrazolopyridines such as tracazolate, which do not bind directly to BZ receptors, but which appear to alter or influence the BZ receptor. Also included are the barbiturates, which act directly on the chloride channel. Tracazolate displays a more anxioselective profile in being relatively less potent at causing sedation, muscle relaxation, or anticonvulsant action compared to its anticonflict activity in animal studies (Petrack & Yokoyama, 1985).

Exactly why a potentiation of GABAergic neurotransmission in the brain results in antianxiety action is still not well understood, but the general notion is that certain areas or systems in the brain involved in anxiety disorders are differentially affected. Just what these areas and systems are remains the topic of considerable discussion, but some light may be shed on this question by examining the remaining nonBZ anxiolytics listed in Table 1.

The Group 2 compounds listed in Table 1 are not only nonBZ in their chemical structures, but in their biochemical and pharmacological properties as well. They do not bind to the BZ receptor nor to other parts of the GABA-BZ-Cl^- ionophore complex. Nevertheless, they display clinical or preclinical indications as antianxiety drugs, and all of them interact with the serotonin system.

Ritanserin is an interesting compound in that it is a serotonin type 2 (5-HT_2) antagonist. Preliminary clinical trials with this agent have suggested efficacy in the treatment of anxiety (Ceulemans et al., 1985). Buspirone and its analogs, gepirone, and TVX Q 7821, also act on the serotonergic system, but they appear to be agonists at the type 1A serotonin (5-HT_{1A}) receptor. These compounds have shown activity in some animal models predictive of anxiolytic activity in humans (Eison et al., 1983; Riblet et al., 1982; Traber et al., 1984). Buspirone is the only compound of this group which has been shown to be a clinically effective anxiolytic (Taylor et al., 1985). Buspirone, gepirone, and TVX Q 7821 bind to 5-HT_{1A} receptors and, based upon electrophysiological and/or biochemical studies, appear to function as agonists or, in some cases, as partial agonists at this receptor. While it may at first seem paradoxical that serotonin agonists and antagonists might both be useful for the same indication, it appears that both types of agents produce similar functional effects in the brain. This common effect, at least for acute administration of these compounds, is to decrease serotonergic neurotransmission in the brain. Ritanserin does this by blocking postsynaptic 5-HT_2 receptors, while buspirone, gepirone, and TVX Q 7821 decrease serotonergic neurotransmission by directly inhibiting the firing of serotonergic neurons in the brain (Gehlbach et al., 1985; Sprouse & Aghajanian, 1985; VanderMaelen & Wilderman, 1984).

The BZs also affect serotonergic neurotransmission in the brain. This notion goes back to the work of Stein and colleagues (Stein et al., 1975) and predates the concept that the BZs achieve their effects via the GABA system. The connection between anxiety, anxiolytic drug efficacy, and the serotonin system has been reviewed recently (Iversen, 1984). The serotonin system is quite well suited for modulating various brain functions (VanderMaelen, 1985). Serotonergic neurons located mainly within the raphe nuclei send axonal projections rostrally and caudally to innervate all levels of the neuroaxis, including limbic structures, the hippocampus, and the cerebral cortex. Stein et al. (1975) showed that methysergide, a serotonin antagonist, had an effect similar to the BZs in the Geller-Seifter conflict procedure. If the BZs were to attenuate the conflict-induced suppression of behavior by reducing serotonergic neurotransmission, one might predict that lesions of the raphe nuclei would have a similar effect. Stein and colleagues (1975) employed 5,6-dihydroxytryptamine as a neurotoxin in just such an experiment. The resulting degeneration of the serotonergic system did, in fact, mimic the effect of the BZs. Similar results were obtained by Tye et al. (1977) using a more specific neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT).

Since similar effects are obtained with the BZs as with serotonin antagonists or lesions of the serotonin system, does this mean that the BZs decrease serotonergic neurotransmission in the brain? Based upon electrophysiological and biochemical studies, the answer appears to be yes. These studies indicate that, at least in unanesthetized animals, there is a decrease in the firing of serotonergic neurons following administration of the BZs (Laurent et al., 1983; Soubrie et al., 1983; Trulson et al., 1982). When the serotonin system is lesioned by 5,7-DHT in rats, diazepam, as well as buspirone and gepirone, lose their anticonflict activities, suggesting that an intact serotonin system is needed in order to observe the anticonflict ("anxiolytic") effects of these drugs (Eison et al., 1986).

Additional studies have looked at the effects of buspirone and gepirone on the firing of serotonergic dorsal raphe neurons (Gehlbach and VanderMaelen, 1985; Gehlbach et al., in preparation; VanderMaelen and Wilderman, 1984a,b; VanderMaelen et al., unpublished). It was found that systemic administration of these drugs very potently inhibited the firing of serotonergic neurons. The ED_{50} for intravenously administered buspirone was 11 μg/kg, and for gepirone the ED_{50} was 25 μg/kg. Using the technique of microintophoresis it was found that these were direct effects of the parent compounds acting on these cells (VanderMaelen and Wilderman, 1984b; VanderMaelen et al., submitted). Figure 1 illustrates some of the electrophysiological results obtained with buspirone, the prototypical agent among the 5-HT_{1A} agonist anxiolytics.

Further studies of buspirone and gepirone were carried out in the isolated brain slice preparation. It was found that buspirone and gepirone, like serotonin, inhibit the firing of 5-HT neurons in the dorsal raphe nucleus (Gehlbach et al., in preparation). Previous work by Aghajanian and VanderMaelen (1982) had shown that another 5-HT_{1A} agonist, LSD, as well as serotonin itself hyperpolarized the membrane and inhibited firing. Aghajanian and Lakoski (1984) have demonstrated that this hyperpolarization is due to an increase in membrane conductance to po-

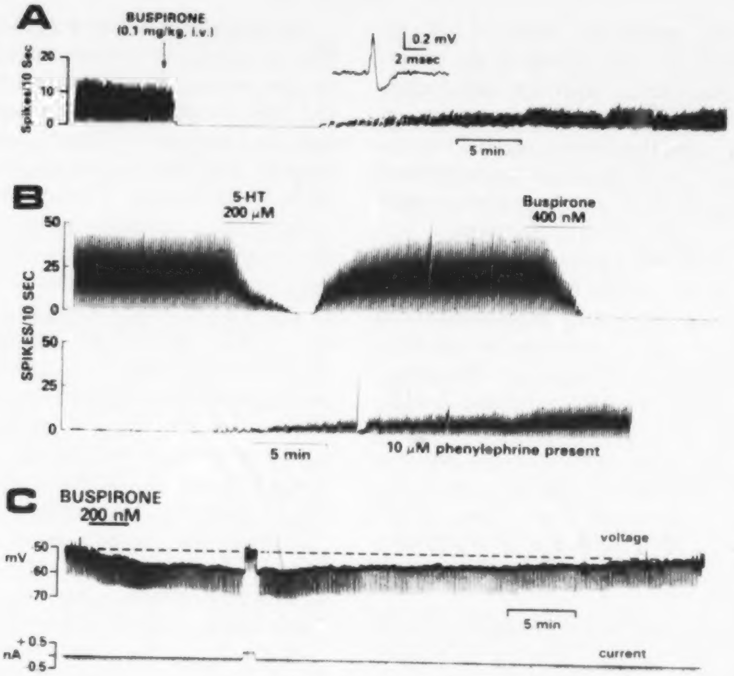

FIGURE 1. A. Inhibition by buspirone of a serotonergic dorsal raphe (DR) neuron recorded extracellularly from a chloral hydrate anesthetized rat. Inset shows oscilloscope tracing of action potential (from VanderMaelen et al., unpublished). B. Inhibition by serotonin and buspirone of a serotonergic DR neuron recorded *in vitro* in a rat brain slice preparation. The IC_{50} for buspirone was 18.9 nM (Gehlbach and VanderMaelen, 1985; Gehlbach et al., in preparation). C. Membrane hyperpolarization and decreased input resistance caused by buspirone, in a serotonergic DR neuron recorded intracellularly in a rat brain slice (VanderMaelen, in press). The step in the voltage and current traces indicates when the membrane was "manually voltage clamped" to the original resting potential to observe the magnitude of the input resistance change (measured by constant current hyperpolarizing pulses) independent of any anomalous rectification.

tassium ions. Intracellular recording experiments (VanderMaelen et al., in press) have shown that buspirone produces an effect similar to that of serotonin; that is, a hyperpolarization of the membrane and a decrease in input resistance, probably indicative of an increase in membrane conductance to potassium ions (Figure 1C). Sprouse and Aghajanian (1985) had looked at the effects of two other 5-HT_{1A} agonists, TVX Q 7821 and LY 165163, and reported similar results. These 5-HT_{1A} compounds all seem to be acting at the serotonin autoreceptor, producing inhibitory effects similar to those of serotonin.

The BZs decrease impulse discharge not only of serotonergic neurons but of noradrenergic and dopaminergic neurons as well (Laurent et al., 1983). Buspirone, on the other hand, decreases neurotransmission only in the serotonin system. In the norepinephrine system (locus coeruleus) and the dopaminergic system (substantia nigra), impulse flow is actually increased (McMillen et al., 1983; Sanghera et al., 1983). So the common effect of the BZs and buspirone is to decrease impulse flow in the serotonergic system.

Gray (1982) has proposed an elaborate theory in which the septohippocampal system plays an important role in anxiety. This system is modulated by monoaminergic systems, including the serotonergic neurons of the raphe nuclei. Yocca and Maayani (1985) studied buspirone and gepirone in the guinea pig hippocampus where serotonin stimulates the production of cyclic AMP. They found that buspirone and gepirone function as partial agonists at the 5-HT$_{1A}$ receptor in the hippocampus. It is significant that essentially the same conclusion has been drawn using electrophysiological techniques in the hippocampus. Andrade and Nicoll (1985) made intracellular recordings from hippocampal pyramidal cells in brain slices and found that buspirone, as well as gepirone, functioned as a partial agonist. Buspirone produced a smaller hyperpolarization of the membrane than serotonin, while in the presence of buspirone, the effect of serotonin was blocked.

This brings up what may be a very important point as far as the pharmacology of buspirone and gepirone are concerned: To what extent is the partial agonist activity of these compounds important, as opposed to the full agonist activity? Buspirone and gepirone may have full agonist activity in the dorsal raphe nucleus; there is no evidence that these compounds block serotonin there. On the other hand, in the hippocampus the main effect of these compounds may be their antagonism of serotonin rather than their agonist activity. It may be that some kind of balance between full agonist and partial agonist activities is required in order for a compound such as this to be effective in the clinic.

Evidence regarding the Group 2 nonBZ anxiolytics supports the notion that a decrease in serotonergic neurotransmission plays some role in anxiolytic mechanisms of action. This, of course, does not mean that all agents which have this action would be clinically effective anxiolytic drugs. LSD, 5-methoxy-N,N-dimethyl tryptamine, and lisuride are just three examples of compounds which inhibit the firing of central serotonergic neurons (VanderMaelen, 1985), but which are not clinically useful in the treatment of anxiety. Nonetheless, a direct and primary involvement of serotonergic systems, that is 5-HT neurons and 5-HT$_{1A}$ receptors, is strongly implicated in the antianxiety mechanism of action of buspirone since neurochemical, receptor binding, and autoradiographic anatomical studies indicate that buspirone binds to, localizes to, and most potently interacts with serotonergic brain systems (Taylor et al., 1985). In addition, a variety of indirect effects on other neurotransmitter systems also occurs, and contributes to the overall pharmacology of buspirone and related compounds (Eison & Eison, 1984; Taylor et al., 1985). These indirect effects may play a critical role in producing the correct combination of pharmacological actions resulting in clinical therapeutic efficacy.

Analysis of 5-HT$_1$ Binding Site Subtypes and Potential Functional Correlates[1]

Stephen J. Peroutka, M.D, Ph.D.,[*][2] Richard E. Heuring,[2] Michael D. Mauk, Ph.D.,[2] and Jeffery D. Kocsis, Ph.D.[2]

Serotonin (5-hydroxytryptamine; 5-HT) has been implicated in a number of human diseases such as anxiety, depression, migraine, and epilepsy. However, a specific role for 5-HT has not been documented in any human disease. Receptor-site analysis is one approach which may elucidate the functional role of 5-HT in the central nervous system (CNS). Since the analysis of M and D receptors in 1957, it has become clear that multiple 5-HT receptors exist. In the past 3 years, a number of novel pharmacologic agents have been developed which have greatly facilitated the analysis of 5-HT receptor subtypes in the CNS. For example, 8-hydroxy-2-N,N-(di-propylamino)tetralin (8-OH-DPAT), RU 24969, ketanserin, and ritanserin have been shown to be potent and selective binding-site subtype agents.

At the present time, at least four distinct subtypes of 5-HT receptors have been identified in brain membranes (Hoyer et al., 1985b). The present report will focus on the current classification of 5-HT$_1$ binding-site subtypes. All 5-HT$_1$ binding-site subtypes can be labeled by ^{3}H-5-HT. Radioligand binding studies have clearly demonstrated that total 5-HT$_1$ binding as defined by ^{3}H-5-HT is heterogeneous in the rat frontal cortex (Pedigo et al., 1981). In studies performed in this laboratory (Peroutka, in press), computer analysis of drug competition curves with total ^{3}H-5-HT binding shows that 5-HT competition with ^{3}H-5-HT binding to total 5-HT$_1$ sites is consistent with a homogeneous receptor population. However, the interactions of *d*-LSD, (m-trifluoro-methylphenyl) piperazine HCl (TFMPP), methysergide, spiperone, and mianserin with total 5-HT$_1$ sites are more consistent with a two-site model of 5-HT$_1$ binding. In addition, computer-assisted curve fitting analysis of RU 24969 competition studies is most consistent with a three-site model of 5-HT_1 binding in rat frontal cortex. 8-OH-DPAT is approximately 10,000-fold selective for the 5-HT_{1A} site versus all other known 5-HT_1 binding site subtypes. As a result, 100 nM 8-OH-DPAT can be used to effectively block ^{3}H-5-HT binding to the 5-HT_{1A} site without markedly affecting the binding or ^{3}H-5-HT to non-5-HT_{1A} sites. Indeed, Scatchard analysis of ^{3}H-5-HT binding in the absence or presence of 100 nM 8-OH-DPAT demonstrates a significant decrease in the B_{max} without markedly affecting the K_D of ^{3}H-5-HT in the rat frontal cortex. Analysis of residual ^{3}H-5-HT binding reveals that the competition curve for RU 24969 is even more shallow than at total 5-HT_1 sites. Computer-assisted analysis reveals that the interactions of methysergide, TFMPP, mianserin, and RU 24969 are still consistent with at least a two-site model of non-5-HT_{1A} binding. No pharmacologic agent could be identified which has more than a 440-fold selectivity for subtypes of putative non-5-HT_{1A} binding.

As a result, 5-HT_{1B} binding in this laboratory was defined as ^{3}H-5-HT binding in the presence of 100 nM 8-OH-DPAT plus 3,000 nM mianserin. 5-HT_{1C} binding in rat frontal cortex was defined as specific ^{3}H-5-HT binding in the presence of 100 nM 8-OH-DPAT plus 10 nM RU 24969. Under these conditions, pharmacological competition studies reveal that each putative 5-HT_1 binding-site subtype has a distinct pharmacological profile (Table 1). The 5-HT_{1B} site has extremely high affinity for RU 24969 (0.38 nM) and relatively high affinity for TFMPP. The 5-HT_{1C} site has relatively high affinity for 5-HT, mianserin, and methysergide.

However, a species study revealed interesting variations in the presence of 5-HT_1 binding site subtypes (Heuring et al., 1986). In both the rat and mouse, RU 24969 distinguishes two distinct subpopulations of non-5-HT_{1A} binding sites. In contrast, RU 24969 interactions with non-5-HT_{1A} binding in guinea pig, dog, human, cow, chicken, turtle, and frog brain membranes are consistent with a single population non-5-HT_{1A} binding-site subtype. These results suggest that certain 5-HT_1 binding-site subtypes are species specific. In particular, the 5-HT_{1B} site (as defined above) appears to be unique to rat and mouse brain membranes.

These data are consistent with the findings of multiple other laboratories. A number of radioligands have been shown to label the 5-HT_{1A} binding site: ^{3}H-8-OH-DPAT (Gozlan et al., 1983; Hall et al., 1985; Peroutka, 1985), ^{3}H-TVX Q 7821 (Dompert et al., 1985), ^{3}H-buspirone (Moon & Taylor, 1985), and ^{3}H-1-(2-(4-aminophenyl)ethyl)-4-(3-trifluoromethylphenyl) piperazine (PAPP) (Asarch et al., 1985). In addition, ^{3}H-WB 4101, previously considered a selective alpha$_1$-adrenergic radioligand, has been demonstrated to label the 5-HT_{1A} site (Norman

TABLE 1. Characteristics of 5-HT_{1A}, 5-HT_{1B}, and 5-HT_{1C} Binding-Site Subtypes

Potent Pharmacologic Agents	5-HT 8-OH-DPAT 5-MeDMT TVX Q 7821 Buspirone RU 24969	5-HT RU 24969	5-HT Mesulergine Mianserin Methysergide

et al., 1985). Regardless of the ^{3}H-ligand used to label the site, it displays high and selective affinity for 8-OH-DPAT, 5-methoxydimethyltryptamine (5-MeDMT), TVX Q 7821, and buspirone. The 5-HT$_{1A}$ site is densely present in the CA1 region and dentate gyrus of the hippocampus and in the raphe nuclei (Glaser et al., 1985; Pazos & Palacios, 1985). In addition, the fact that 5,7-dihydroxytryptamine-induced lesions of the raphe system cause a loss of ^{3}H-8-OH-DPAT binding in the striatum but not hippocampus has led Hamon and colleagues to hypothesize that ^{3}H-8-OH-DPAT may also label a presynaptic 5-HT autoreceptor (Gozlan et al., 1983).

The putative 5-HT$_{1B}$ site has been labeled in rat brain with I^{125} cyanopindolol (Hoyer et al., 1985a; Pazos et al., 1985). The I^{125} cyanopindolol (I^{125}CYP) site has high affinity for 5-HT and RU 24969 and relatively low affinity for *d*-LSD and 8-OH-DPAT. The highest densities of 5-HT$_{1B}$ sites in rat brain are found in the caudate nucleus, superior colliculus, lateral geniculate body, subiculum, and substantia nigra (Pazos & Palacios, 1985a).

The 5-HT$_{1C}$ site was first characterized in membranes from pig choroid plexus and cortex (Pazos et al., 1984). The site was labeled by both ^{3}H-5-HT and ^{3}H-mesulergine. Independently, Yagaloff and Hartig (1985) labeled the site with I^{125} LSD in the rat choroid plexus. The site has high affinity for 5-HT, methysergide, and mianserin and relatively low affinity for RU 24969. Another 5-HT$_1$ binding-site subtype having low affinity for RU 24969 has been identified in the bovine striatum (Peroutka, 1985). The relationship between putative 5-HT$_{1C}$ sites in rat, bovine, and pig brain is currently being investigated in this laboratory.

A number of functional correlates of the 5-HT$_1$ class of binding sites have been proposed (Peroutka, 1984) (Table 2). In particular, the extensive characterization of the 5-HT$_{1A}$ binding-site subtype has enabled an analysis of this putative receptor in many 5-HT-mediated effects. For example, the ability of 5-HT$_{1A}$ selective drugs to stimulate a 5-HT sensitive cyclase (Shenker et al., 1985) and the potent effects of guanosine triphosphate (GTP) on ^{3}H-8-OH-DPAT binding (Schlegel & Peroutka, in press) suggest a linkage of the 5-HT$_{1A}$ site to an adenylate cyclase. A role for the 5-HT$_{1A}$ site has been proposed for the mediation of certain components of the 5-HT behavioral syndrome (Smith & Peroutka, in press; Tricklebank et al., in press), canine basilar artery contractions (Peroutka, Huang, et al., in press; Taylor et al., in press), the potentiation of ejaculation and/or seminal emissions (Kwong et al., in press), hypothermia (Gudelsky et al., 1985; Middlemiss et al., 1985), and hypotensive effects of 5-HT (Doods et al., 1985).

The interactions of 5-HT$_{1A}$ selective agents have also been analyzed in an in vitro rat hippocampal slice preparation. Application of 8-OH-DPAT, buspirone, or TVX Q 7821 leads to a dose-dependent decrease in the amplitude of the population spike (Peroutka, Mauk, et al., in press). Ketanserin, a selective 5-HT$_2$ antagonist, has no independent effect on the amplitude of the population spike. In addition, ketanserin has no effect on the buspirone or TVX Q 7821-induced inhibition of the CA1 population spike. In addition, Beck et al. (1985) have shown that spiperone partially blocks 5-HT-induced changes in the CA1 population spike. Therefore, modulation of hippocampal CA1 neuronal activity may be a functional correlate of 5-HT$_{1A}$ receptor activation.

The 5-HT$_{1B}$ site has recently been analyzed in terms of the 5-HT "autoreceptor." A significant correlation has been found between the potencies of drugs at the 5-HT$_{1B}$ site as labeled by I^{125} cyanopindolol and the "autoreceptor" (Engel et al., 1986). Finally,

TABLE 2. Proposed Functional Correlates of 5-HT$_1$ Binding-Site Subtypes

5-HT$_{1A}$
Adenylate cyclase stimulation
Forepaw treading, tremor, head-weaving
Canine basilar artery contractions
Facilitation of ejaculation and/or seminal emissions
Hypothermia
Hypotensive effects
CA1 Hippocampal inhibition
5-HT$_{1B}$
"Autoreceptor"
5-HT$_{1C}$
Phosphoinositide turnover

preliminary studies suggest that phosphoinositide turnover may be mediated by the 5-HT_{1C} sites in rat choroid plexus (Sanders-Bush & Conn, 1986).

Clearly, significant progress in the analysis of 5-HT_1 binding-site subtypes has been made in the past few years. Future studies will be directed at obtaining more selective radioligands or relatively "pure" regions or species. Ideally, a radioligand should label a homogeneous population of receptors. Finally, although substantial progress is being made, the role of 5-HT in the CNS is still quite unclear. Functional correlates of 5-HT_1 binding-site subtypes may significantly add to the understanding of the role of 5-HT in the CNS.

Labeling of the 5-HT_{1A} Receptor Subtype

Jean C. Shih, Ph.D.,[1] Kenneth B. Asarch, Pharm.D., Ph.D.,[1] and Richard Ransom, Ph.D.[1]

Introduction

We have been searching for an affinity ligand suitable for labeling the serotonin (5-HT) receptor protein in order to characterize and purify the receptor. Initial ligands studied were two serotonin derivatives, N-(2-nitro-4-azidophenyl)-serotonin (NAP-serotonin) (Cheng and Shih, 1979) and 3-[β-(4-azidobenzamidino) ethyl] -5-hydroxyindole (serotonin azidobenzamidine) (Ransom et al., 1985a). The high nonspecific binding of these two compounds prevents them from serving as useful receptor probes. NAP-serotonin is however useful as a photoaffinity probe for monoamine oxidase (Chen et al., 1984, 1985a, 1985b) and serotonin azidobenzamidine can cause a specific photoinactivation of synaptosomal uptake of serotonin (Ransom et al., 1985a). Dr. Ray Fuller at Eli Lilly and Co. had studied a series of phenylpiperazine derivatives which displayed high affinity for serotonin receptors (Fuller, 1980). We obtained four derivatives and synthesized numerous others. These derivatives were then converted into photoactivatable azido derivatives and their potencies determined at 5-HT_1 sites labeled with [^{3}H]5-HT and 5-HT_2 sites labeled with [^{3}H] spiperone. A partial listing of these compounds is presented in Figure 1. It was found that some of the most potent phenylpiperazines possessed phenethyl substituents on the piperazine nitrogen (Ransom et al., 1985b) and that substitution on the phenyl ring of the phenethyl substituent was not critical in determining potency at 5-HT_{1A} binding sites. It was also determined that displacement of [^{3}H]5-HT by certain of these compounds was distinctly biphasic (Ransom et al., 1985b). Extensive work has been performed to demonstrate that 1-[2-(4-aminophenyl) ethyl]-4 -(3-trifluoromethylphenyl) piperazine (LY 165163; p-NH_2-PE-TFMPP or PAPP) is a selective 5-HT_{1A} ligand and 1-[2-(4-azidophenyl) ethyl]-4-(3-trifluoromethylphenyl) piperazine (p-azido-PAPP) is a selective 5-HT_{1A} photoprobe (structures shown in Figure 2).

Discrimination of 5-HT_1 Subtypes by PAPP

[^{3}H]5-HT binding assays were conducted as previously described (Asarch et al., 1985). Binding assays were carried out at 37°C in 50 mM Tris-HCl, pH 7.4, containing 1 mM EDTA, 5 mM $CaCl_2$, 10 μM pargyline, and 0.1 percent ascorbic acid. We have found that the $CaCl_2$ in the binding medium minimizes lipid peroxidation (Muakkassah-Kelly et al., 1983) and the ascorbic acid prevents oxidation of the [^{3}H]5-HT during the assay (Andresen & Shih, in press). As shown in Figure 3 and Table 1, PAPP discriminates a similar proportion of high and low affinity sites as does spiperone and displays selectivity for the 5-HT_{1A} subtype (Asarch et al., 1985). In the presence of 1 μM spiperone, a concentration that blocks the 5-HT_1 binding sites without affecting 5-HT_{1B} binding sites (Pedigo et al., 1981), PAPP displays only a single low affinity (213 nM) in the rat cortex (Table 1). Interestingly, the trifluoromethylphenyl piperazine (TFMPP) portion of the molecule displays an opposite selectivity to PAPP (Table 1, Asarch et al., 1985). In addition, TFMPP binds to subsets of binding sites of 5-HT_{1B} binding sites as evidenced by the statistically significant 2 site fit for the displacement of [^{3}H]5-HT binding to rat cortical membranes in the presence of a 1 μM spiperone mask of the 5-HT_{1A} binding sites (Table 1).

FIGURE 1. Potency of photoaffinity labeling probes for [^{3}H]5-HT and [^{3}H]spiperone binding sites. All compounds were synthesized in our laboratory. IC$_{50}$ values were determined from competition experiments in rat cortical membranes in the dark using either 2 nM [^{3}H]5-HT or 1 nM [^{3}H]spiperone as described previously (Ransom et al., 1985). Two IC$_{50}$ values are reported when a two-site model provided a statistically significant better fit than a single site model.

[^{3}H]PAPP Binding

[^{3}H]PAPP was obtained through the catalytic reduction of a ring-brominated analog of PAPP as previously described (Ransom et al., 1986). [^{3}H]PAPP binding assays were carried out under the same conditions as the [^{3}H]5-HT binding assays after appropriate validation (Ransom et al., 1986). [^{3}H]PAPP bound to a single population of sites with a K$_D$ of 1.6 nM and a B$_{max}$ of 162 fmol/mg protein. The Hill coefficient was not statistically different from 1. [^{3}H]PAPP binding in different brain areas was compared with the density of 5-HT$_{1A}$ sites present in various regions. As shown in Table 2, the density of [^{3}H]PAPP sites in hippocampus, cortex, striatum, and cerebellum were very similar to the density of 5-HT$_{1A}$ receptors in these areas.

Several drugs were used to characterize the pharmacology of [^{3}H]PAPP binding to rat cortical membranes. The potency of these agents as inhibitors of [^{3}H]PAPP binding and at 5-HT$_{1A}$ binding sites compare very well

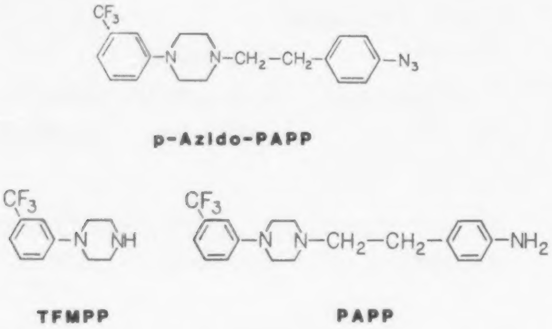

FIGURE 2. Chemical structure of 1-(*m*-trifluoromethylphenyl)-piperazine (TFMPP); 1-[2-(4-aminophenyl) ethyl]-4-(3-trifluoromethylphenyl) piperazine (PAPP); and 1-[2-(4-azidophenyl) ethyl]-4-(3-trifluoromethylphenyl) piperazine (p-Azido-PAPP).

(Table 3). Competition by each drug, including the selective agents spiperone and 8-hydroxy-2-N, N-(di-propylamino)tetralin (8-OH-DPAT), were best modeled as a single site displacement. Further support for the association of [^{3}H]PAPP binding to a 5-HT$_1$ receptor is provided by the very low affinity (K_D = 1,000 nM) exhibited by ketanserin (Janssen) in competition experiments. Because ketanserin has a very high affinity for the 5-HT$_2$ receptor (Leysen et al., 1982), this result also demonstrates that [^{3}H]PAPP at 1 nM does not bind to 5-HT$_2$ receptors. The inhibition of [^{3}H]PAPP binding by maximal doses of all drugs tested was not increased in the presence of 10 μM 5-HT indicating that the displacement observed for every drug occurred from the same population of sites. [^{3}H]PAPP binding was not affected by nonserotonergic agents such as norepinephrine, phenylephrine, prazosin, isoproterenol, dopamine, haloperidol, histamine, pyrilamine, atropine, imipramine, and desmethylimipramine at concentrations which would occupy their specific receptors.

Coupling of [^{3}H]PAPP Binding Sites

[^{3}H]5-HT binding sites have been demonstrated to be regulated by guanosine triphosphate (GTP) and divalent cations (Mallat and Hamon, 1982). It was therefore of interest to determine if 5-HT$_{1A}$ binding sites measured by [^{3}H]PAPP were similarly affected. GTP produces a parallel inhibition of [^{3}H]5-HT and [^{3}H]PAPP specific binding in rat hippocampus measured at K_D concentrations of each radioligand (data not shown). Under the same conditions, 5 mM $MgCl_2$, $CaCl_2$, or $MnCl_2$ produces a 99 percent, 66 percent, or 82 percent increase in [^{3}H]PAPP specific binding in rat hippocampus similar to the increases reported for [^{3}H]5-HT specific binding in rat hippocampus (Hamon et al., 1983). Similar effects of GTP and divalent cations on 5-HT$_{1A}$ binding sites have been ported using other radioligands (Hall et al., 1985; Norman et al., 1985). In the presence of both GTP and divalent cations 5-HT will stimulate adenylate cyclase in the adult rat hippocampus (Barbaccia et al., 1983). Under similar conditions PAPP produces about one-half the stimulation of adenylate cyclase (EC_{50} = 30 nM) produced by serotonin (EC_{50} = 100 nM). This finding is consistent with the results of Shenker et al. (1985) who report in the adult guinea pig hippocampus that 5-HT

TABLE 1. Binding Parameters for Displacement of [^{3}H]5-HT by Spiperone, TFMPP, and PAPP.

Drug	K_H (nM)	B_H (%)	K_L (nM)	B_L (%)
			Cortex	
Spiperone	19.3 ± 4.2	38 ± 1.0	36700 ± 5200	62 ± 1.0
TFMPP	5.6 ± 2.7	52 ± 3.7	172 ± 75	48 ± 3.7
PAPP	2.9 ± 0.5	44 ± 2.7	328 ± 73	56 ± 2.7
		Cortex in Presence of 1 μM Spiperone		
TFMPP	6.0 ± 2.0	63 ± 2.5	273 ± 6.2	37 ± 2.5
PAPP	213 ± 27	100		

The values listed were obtained in rat cortex from at least three competition experiments for each inhibitor. K_H and K_L are the apparent dissociation constants for the high and low affinity sites (± S.E.M.) and were calculated by taking the geometric mean of the computer derived parameters for individual experiments. B_H and B_L are the proportions of high and low affinity sites (± S.E.M.) calculated by taking the arithmetic mean of the computer generated parameters for individual experiments. These parameters were determined at 2 nM [^{3}H]5-HT using 10 μM unlabeled 5-HT to define 100 percent displacement.

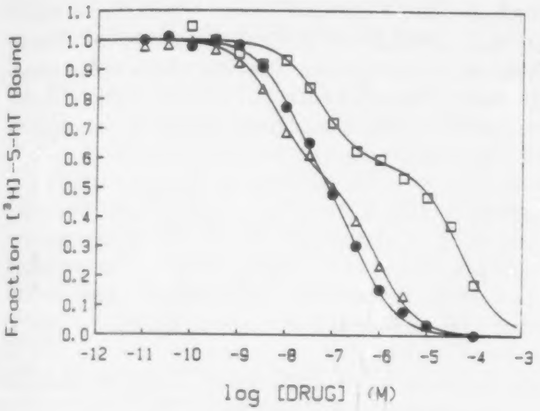

FIGURE 3. Inhibition of [^{3}H]5-HT binding in rat cortex. The data for each curve are from one experiment in rat cortex which was replicated at least three times. Each point is the mean of triplicate determinations which varied by less than 5 percent at each concentration tested. The curves were fitted to the data by computer according to a two-site model (spiperone □, TFMPP ●, and PAPP Δ.

stimulates adenylate cyclase via the 5-HT$_{1A}$ receptor at low concentrations and at higher concentrations further stimulates adenylate cyclase via a yet to be characterized non-5-HT$_{1A}$ receptor.

p-Azido-PAPP Binding Properties

p-Azido-PAPP is readily synthesized from PAPP via a diazotization reaction described previously (Ransom et al., in press). p-Azido-PAPP displays selectivity for the 5-HT$_{1A}$ ing site similar to PAPP. Inhibition of [^{3}H]5-HT binding in the rat hippocampus by both p-azido-PAPP and spiperone fit a two-site model significantly better than a single site model, discriminate the same fraction of sites, and both have higher affinity for 5-HT$_{1A}$ sites (Table 4).

TABLE 2. Regional Densities of 5-HT$_{1A}$ Receptors and [^{3}H]PAPP Binding Sites.

	B$_{max}$ (fmole/mg of protein)	
Brain Region	5-HT$_{1A}$	[^{3}H]PAPP
Hippocampus	366 ± 39	399 ± 38
Cerebral Cortex	123 ± 14	162 ± 20
Corpus Striatum	44 ± 5	52 ± 8
Cerebellum	None	None

5-HT$_{1A}$ receptor densities were determined from [^{3}H]5-HT binding isotherms by the method of Scatchard (1949) using 1 μM 8-OH-DPAT to define nonspecific binding. [^{3}H]PAPP site densities were similarly quantitated in the same synaptic membrane preparation in three separate experiments. Data are mean ± S.E.M. values of the triplicate determinations.

TABLE 3. Affinities of Serotonergic Drugs for 5-HT$_{1A}$ and [^{3}H]PAPP Binding Sites.

	K$_i$ (nM)	
Drug	5-HT$_{1A}$	[^{3}H]PAPP
8-OH-DPAT	2.5	2.8
PAPP	2.9	2.9
d-LSD	3.6	2.5
5-HT	10	18
Spiperone	26	40
Ketanserin	471	1,000

5-HT$_{1A}$ affinities were determined at 2 nM [^{3}H]5-HT by nonlinear regression analysis. PAPP, 8-OH-DPAT and spiperone discriminated two [^{3}H]5-HT binding subpopulations, with the higher affinity site corresponding to the 5-HT$_{1A}$ receptor. 5-HT, d-LSD, and ketanserin displaced [^{3}H]5-HT from a single site. [^{3}H]PAPP binding sites were determined at 1 nM. Ten micromolar 5-HT was used to define nonspecific binding for each radioligand. The values are representative of multiple experiments for each competitor in which at least 12 concentrations of inhibitor were examined in each experiment.

Reversible [^{3}H]p-Azido-PAPP Binding

[^{3}H]p-Azido-PAPP was synthesized from [^{3}H]PAPP (Ransom et al., in press). [^{3}H]p-Azido-PAPP binding experiments were performed in the dark in a similar manner to that previously described for [^{3}H]PAPP and [^{3}H]5-HT (Ransom et al., in press). The binding in the dark was completely reversible as demonstrated by the complete disappearance of specific binding within 4 minutes after addition of 10 μM 5-HT. Saturation binding isotherms showed that [^{3}H]p-azido-PAPP labels a single class of binding sites in rat hippocampal membranes with a K$_D$ of about 1 nM and a B$_{max}$ of 370 fmol/mg protein. The density of [^{3}H]p-azido-PAPP sites in hippocampus agrees with the density of 5-HT$_{1A}$ receptors in this tissue (Ransom et al., in press). Serotonergic drugs were used to compare their potency at [^{3}H]p-azido-PAPP binding sites in the dark with their potency at the 5-HT$_{1A}$ receptors (Table 5). For all compounds studied there is a strong correlation between their affinities for the 5-HT$_{1A}$ receptors and [^{3}H]p-azido-PAPP binding sites. In addition, high concentrations (10 μM) of other monoamine neurotransmitters such as dopamine, norepinephrine, and histamine did not inhibit [^{3}H]p-azido-PAPP binding to hippocampal membranes.

Photodependent Irreversible Binding of [^{3}H]p-Azido-PAPP

Photolysis experiments with [^{3}H]p-azido-PAPP were designed to take advantage of the compound's high affinity for the 5-HT$_{1A}$ receptor. Membranes were incubated with 10 nM [^{3}H]p-azido-PAPP at 37°C, cooled on ice, and then washed in order to reduce the nonspecific binding prior to photolysis (Ransom et al., in press). The washed membranes were resuspended at a concentration of approximately 100 μg protein/ml in photolysis buffer. Photolysis was then carried out by irradiation of the samples on ice for 2 minutes using an Hanovia 450 watt medium pressure mercury lamp at a distance of 20 cm through a filter of Kimax glass (2 mm). Following irradiation the membranes were centrifuged at 50,000 × g for 10 min, solubilized in 20 mM Tris-HCl, pH 7.4, containing 1 percent sodium dodecyl sulfate (SDS), and then subjected to SDS-polyacrylamide gel electrophoresis using a 3 percent stacking gel and a separating gel of 7.5 percent acrylamide. The incorporation of radioactivity into membrane polypeptides upon irradiation in the presence and absence of 1 μM 5-HT is shown in Figure 4. A single peak of radioactivity representing 10 percent incorporation migrates as a 55,000 dalton polypeptide and is completely protected by 5-HT. No incorporation of radioactivity into the 55 kD polypeptide occurs if membranes are incubated with [^{3}H]p-azido-PAPP but not irradiated. Evidence that this polypeptide is associated with the 5-HT$_{1A}$ receptor is indicated by the ability of the following agents with high affinity for 5-HT$_{1A}$ sites to completely block incorporation of radioactivity into the 55 kD band at a concentration of 1 micromolar: 5-HT, 8-OH-DPAT, d-LSD (National Institute of Drug Abuse), metergoline (Farmitalia), spiperone (Janssen Pharmaceutica), TVX Q 7821 (Troponwerke), and buspirone (Bristol). Evidence of the specificity of the incorporation is the inability of the following nonserotonergic agents to block the photodependent incorporation at a concentration of 10 micromolar: norepinephrine, dopamine, haloperidol (Janssen), histamine, pyrilamine, and atropine. In addition ketanserin failed to block incorporation at a concentration of 1 micromolar thus indicating that the 5-HT$_2$ binding site was not labeled.

Conclusions

The results presented indicate that both [^{3}H]PAPP and [^{3}H]p-azido-PAPP can reversibly label the 5-HT$_{1A}$ receptor site and that [^{3}H]p-azido-PAPP, upon irradiation, covalently labels a polypeptide that is, or is a subunit of, the 5-HT$_{1A}$ receptor. We intend to use PAPP as an affinity column ligand with which to try to purify the serotonin receptor, and to use [^{3}H]p-azido-PAPP to identify the purified 5-HT$_{1A}$ receptor.

5-HT$_{1A}$ affinities were determined at 2 nM [^{3}H]5-HT in rat hippocampus. The concentration of [^{3}H]p-azido-PAPP was 1 nM. At least 16 concentrations of each inhibitor were used to determine the K_i values which represent the results from at least three experiments for each competitor.

Dr. Bryan B. Molloy at Eli Lilly and Company for initially providing LY 165163, the compound referred to here as PAPP. We are grateful to the Neurosciences Branch, National Institute of Mental Health, for synthesizing the PAPP and p-azido-PAPP.

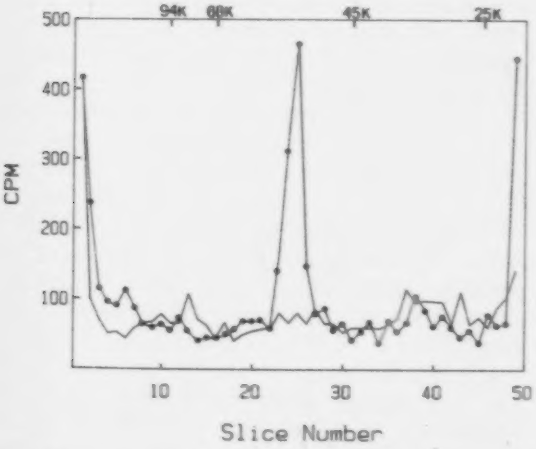

FIGURE 4. SDS-PAGE of [^{3}H]p-azido-PAPP labeled hippocampal membranes. The membranes were incubated with 10 nM [^{3}H]p-azido-PAPP at 37°C for 5 min and then washed and irradiated. The marked (●) line represents incorporation of the label in the absence of an additional agent. The unmarked line is the polypeptide labeling pattern when 1 μM 5-HT was present during the 37°C incubation. The molecular weight markers used were: 94,000, phosphorylase b; 68,000, reindeer serum albumin; 45,000, ovalbumin; 25,000, α-chymotrypsinogen.

Substituted Phenylpiperazines as Serotonin Agonists: Structural Determinants of Potency and Interaction With Receptor Subtypes

Ray W. Fuller, Ph.D.[1]

1-(*m*-Trifluoromethylphenyl)piperazine (TFMPP) and 1-(m-chlorophenyl)piperazine (mCPP) are centrally acting serotonin agonists (Fuller et al., 1978; Samanin et al., 1979). They have structural similarity to quipazine (Hong et al., 1969) and to MK-212 [6-chloro-2-(1-piperazinyl)-pyrazine] (Clineschmidt, 1979), two arylpiperazines previously known to be serotonin agonists. Several other phenylpiperazines besides TFMPP and mCPP also interact with serotonin receptors, and within the chemical series are compounds having markedly different selectivity for serotonin receptor subtypes. Selected phenylpiperazines (structures in Figure 1) and their characteristics in interacting with central and peripheral serotonin receptors are described in this paper.

TFMPP and mCPP moieties are present in the structures of several drugs, and TFMPP and mCPP have been identified as metabolites of some of the drugs listed at the bottom of Figure 1 (Caccia et al., 1985). TFMPP and mCPP may contribute to some of the pharmacologic actions of those drugs. For instance, mCPP is a metabolite of trazodone and has been shown to account for some of the pharmacologic actions of trazodone in laboratory animals; its possible involvement in the pharmacologic actions of trazodone, including antidepressant efficacy clinically, has been considered (Caccia et al., 1982; Maj et al., 1979).

Radioligand Binding

The structure-activity relationship studies of phenylpiperazines as serotonin agonists in the Lilly Research Laboratories were initially based on tritiated serotonin binding to rat brain 5–HT1 receptors (Fuller et al., 1980). Subsequently it was recognized that TFMPP and mCPP had preferential affinity for the 5-HT1B receptor subtype (Sills et al., 1984). This characteristic distinguished them from trazodone, which had preferential affinity for 5-HT2 receptors (*see* Fuller et al., 1984). Recently the study of LY 165163, which was being evaluated as a promising precursor to a photoaffinity label—the azido derivative, was found to have selective affinity for the 5-HT1A site (Asarch et al., 1985). With only a relatively few phenylpiperazines characterized in terms of serotonin receptor subtype selectivity, compounds selective for 5-HT1A,

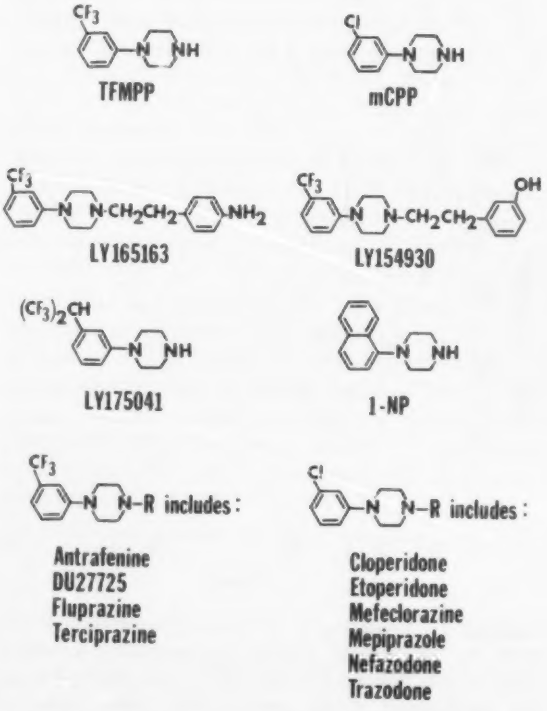

FIGURE 1. Chemical structures of some m-halophenylpiperazines that affect serotonergic function and/or have psychotropic actions.

---

[1] Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285.

5-HT1B, and 5-HT2 receptors have already been found. A more complete study of the receptor subtype selectivity of phenylpiperazines is likely to be a fruitful area of research.

Effects on Brain Serotonin Turnover

Serotonin agonists that act centrally cause a decrease in serotonin turnover. Such a decrease has been measured as a reduction in steady-state concentrations of 5-hydroxyindole-acetic acid (5-HIAA), the major metabolite of serotonin, and a reduction in the rate of 5-HIAA accumulation after probenecid administration to inhibit its efflux from brain (Figure 2). Table 1 shows that TFMPP caused a decrease in 5-HIAA concentration in mouse brain (as reported earlier for rat brain [Fuller et al., 1978]), along with small increases in serotonin concentration. Apparently the compound acts centrally as a serotonin agonist in mice as it does in rats. The decrease in serotonin turnover also has been measured as a reduction in the rate of serotonin depletion after inhibition of its synthesis and a reduction in the rate of 5-hydroxytryptophan (5-HTP) accumulation after decarboxylase inhibition. The latter effect of TFMPP is shown by the data in Table 2. The accumulation of 5-HTP was reduced by TFMPP, both in hypothalamus and in striatum, in rats.

TABLE 1. Effect of TFMPP on 5-Hydroxyindole Concentrations in Mouse Brain.

Dose of TFMPP mg/kg (i.p.)	5-Hydroxyindoles, pmol/g	
	Serotonin	5-HIAA
0	1249 ± 59	737 ± 35
1	1343 ± 31	648 ± 32
3	1582 ± 109 *(+27%)	540 ± 40 *(−27%)
10	1479 ± 39 *(+18%)	501 ± 26 *(−32%)
30	1561 ± 36 *(+25%)	455 ± 31 *(−38%)

Mean values ± standard errors for 5 mice per group treated 2 hrs before they were killed are shown.

* indicates significant ($p < .05$) drug effects.

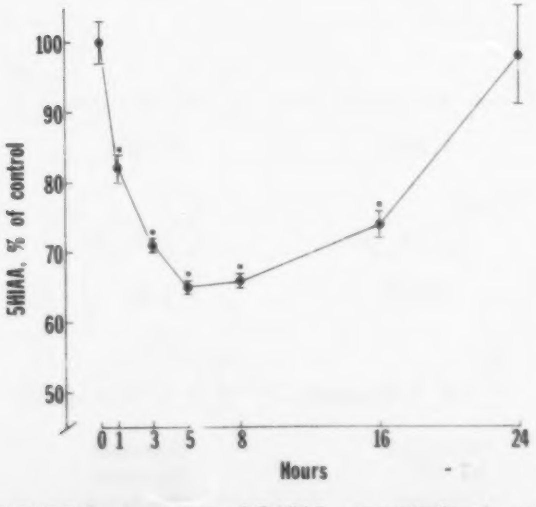

FIGURE 2. Lowering of 5-HIAA concentration in rat brain by LY 165163. 5-HIAA concentration in whole brain of rats treated with LY 165163 (20 mg/kg i.p.) at the designated times before rats were killed is expressed as percentage of the control mean (5 rats per group). Asterisks indicate significant differences ($p<.05$) from the control group.

Neuroendocrine Effects

Since brain serotonin neurons appear to participate in the regulation of pituitary hormone secretion, it is not surprising that central serotonin agonists including phenylpiperazines affect the secretion of pituitary hormones. Table 3 shows that mCPP administration increased serum concentrations both of corticosterone and of prolactin in rats. The increases are like those produced by TFMPP, which also has been shown to increase adrenocorticotropin (ACTH) levels in rat plasma and to decrease hypothalamic content of corticotropin releasing factor (CRF) (Hashimoto et al., 1982), supporting the idea that stimulation of central serotonin receptors in rats leads to increased CRF release from hypothalamus as the cause of the increased blood levels of ACTH and corticosterone.

TABLE 2. Effect of TFMPP on 5-HTP Accumulation After Decarboxylase Inhibition in Rat Brain.

Dose of TFMPP mg/kg s.c.	5–HTP accumulated, nmol/g	
	Hypothalamus	Striatum
0	1.64 ± .13	0.89 ± .006
10	0.65 ± .06*	0.38 ± .04*

Mean values ± standard errors for 5 rats per group are shown. The decarboxylase inhibitor, NSD 1015 (100 mg/kg i.p.), was injected 35 min before rats were killed and 30 min after TFMPP.

*Indicates significant difference from control group ($p < .05$).

mCPP has now been shown to elevate prolactin and glucocorticoid concentrations in primates, including rhesus monkeys and humans, and may be useful in clinical studies to evaluate the functional state of central serotonin receptors (Mueller et al., 1985).

Other Central Effects

Substituted phenylpiperazines are reported to have a variety of other central effects, probably as a consequence of serotonin receptor stimulation. Appetite suppressant activity was the basis for an early patent on mCPP (U.S. Patent 3,253,989, May 31, 1966) before its mechanism of action was known; reduction of food intake by mCPP, TFMPP, and other phenylpiperazines has been observed in several types of animal experiments (e.g., Fuller et al., 1981; Samanin et al., 1979). TFMPP serves as a discriminative stimulus in drug discrimination procedures (Glennon et al., 1984) and suppresses locomotor activity in rats (Lucki & Frazer, 1982). mCPP stimulates the flexor reflex in spinal rats (Maj & Lewandowska, 1980), blocks jumping and paw licking in the rat hot-plate test for analgesia (Rochat et al., 1982), and has anti-aggressive effects (Hahn et al., 1982).

Peripheral Serotonin Receptors

TFMPP and mCPP have little agonist activity at serotonin receptors mediating contraction of the rat jugular vein and instead are antagonists at these receptors (Cohen & Fuller, 1983), which have been characterized as 5-HT2 receptors (Cohen et al., 1981). Other phenylpiperazines, such as 1-naphthylpiperazine (1-NP) (refer to Figure 1), also are serotonin agonists centrally but are antagonists at vascular serotonin receptors (Cohen et al., 1983). TFMPP antagonizes rather than mimics the diarrhea-producing effects of 5-HTP in mice, suggesting it is an antagonist at gut serotonin receptors mediating that effect (Warrick et al., 1981). TFMPP and mCPP also have high affinity for the serotonin receptor that mediates contraction of the rat fundus but have relatively low efficacy as agonists; LY 165163 has affinity for this receptor but no efficacy as an agonist (Cohen & Wittenauer, 1986).

TABLE 3. Effect of mCPP on Serum Hormone Concentrations in Rats.

Dose of mCPP mg/kg (i.p.)	Corticosterone µg/100 ml	Prolactin ng/ml
0	4.6 ± 0.7	7.2 ± 1.8
5	13.1 ± 2.3*	35.5 ± 8.0*
10	47.2 ± 7.0*	55.8 ± 15.8*

Mean values ± standard errors for 5 rats per group are shown. Measurements were made 1 hr after mCPP treatment.

* indicate significant increases ($p < .05$).

Perhaps TFMPP and mCPP act primarily as antagonists at 5-HT2 receptors whether they occur centrally or peripherally; the central serotonin agonist properties of these compounds may be mediated by serotonin receptors other than 5-HT2 receptors. Further evidence bearing on this possibility is needed.

Summary

Several phenylpiperazines are known to affect serotonergic neuronal systems. Among these compounds, some act predominantly as serotonin agonists centrally (e.g., TFMPP and mCPP), whereas others act predominantly as serotonin antagonists (e.g., trazodone). Phenylpiperazines have shown preferential affinity by radioligand displacement for 5-HT1A (LY 165163), 5-HT1B (TFMPP and mCPP), or 5-HT2 (trazodone) receptors. Phenylpiperazines (such as TFMPP and mCPP) may act centrally as serotonin agonists but act peripherally (vascular and gut receptors) as serotonin antagonists; these differences might relate to different subtypes of serotonin receptors being involved in the effects studied. Further characterization of phenylpiperazines may identify additional compounds as useful pharmacologic tools and potential therapeutic agents.

Effector Systems Coupled to Serotonin Receptors in Brain: Serotonin Stimulated Phosphoinositide Hydrolysis

Elaine Sanders-Bush, Ph.D.,[1] and
P. Jeffrey Conn, Ph.D.[1]

Central serotonin (5HT) receptors have been classified into two major subtypes, 5HT-1 and 5HT-2, based on radioligand binding studies (Peroutka & Snyder, 1979). Recent evidence suggests that the 5HT-1 binding site can be further subdivided into three subtypes, 5HT-1A, 5HT-1B, and 5HT-1C (Pedigo et al., 1981; Pazos et al., 1984; Yagaloff & Hartig, 1985). The challenge of the future is to determine if these various binding sites are functional receptors which mediate the synaptic action of 5HT. Identification of the biochemical transducing systems which are linked to these recognition sites is one important way to evaluate their role.

Two major transducing mechanisms which mediate signal transmission for neurotransmitters and hormones are the adenylate cyclase/cyclic AMP signal cascade and phospholipase C mediated hydrolysis of polyphosphoinositides. Neurotransmitter mediated activation of adenylate cyclase leads to an increase in intracellular cyclic AMP levels, which serves as a second messenger. The signal cascade then proceeds via cyclic AMP protein kinase mediated protein phosphorylations to final physiological responses (Browning et al., 1985). The second major signaling pathway, the phospholipase C/phosphoinositide hydrolysis mechanism, utilizes inositol lipids [phosphatidylinositol (PI), phosphatidylinositiol-4-phosphate (PIP), and phosphatidylinositol-4, 5-bisphosphate (PIP2)] in the membrane as a first step in the transducing mechanism (Figure 1). It is generally thought that activation of phospholipase C leads to the hydrolysis of PIP2 and the formation of two products, which act as second messengers to elicit cellular responses. One of these products, inositol-1,4,5-trisphosphate (IP3), elevates cytosol calcium levels by releasing intracellular storage pools. Calcium ions then serve as a "third messenger," activating specific protein kinases to evoke responses such as muscle contraction and neurotransmitter release. The second product, diacylglycerol, stimulates protein kinase C, an enzyme which in turn regulates the activity of enzymes by phosphorylating them. The physiological consequences of protein kinase C activation have not been completely worked out, but evidence is emerging that this enzyme is involved in a number of processes, including heterologenous receptor desensitization and control of cell division and differentiation. Another important consequence of the rise in diacylglycerol is the release of arachidonic acid, which leads to the formation of prostaglandins and leukotrienes. These "icosanoids" have numerous cellular effects. The phospholipase C/phosphoinositide hydrolysis cascade mediates signal transduction for a variety of neurotransmitter and hormone receptors, including muscarinic cholinergic, alpha-1 adrenergic, and H-1 histaminergic sites. Interested readers are referred to recent reviews for additional information about this important signaling pathway (Berridge, 1984; Hirasawa & Nishizuki, 1985). 5HT receptors in brain are apparently linked to both the adenylate cyclase and the phosphoinositide hydrolysis pathways. Because of space limitations, this article focuses on the recent studies of 5HT stimulated phosphoinositide hydrolysis. Studies of 5HT activated adenylate cyclase have been extensively reviewed by Middlemiss (1982), Fillion (1983), and Sanders-Bush and Conn (1986).

5HT stimulated phosphoinositide hydrolysis was first characterized in insect salivary gland, where it is involved in the regulation of saliva secretion (Berridge & Heslop, 1981). Limited studies by Berridge et al. (1982) sug-

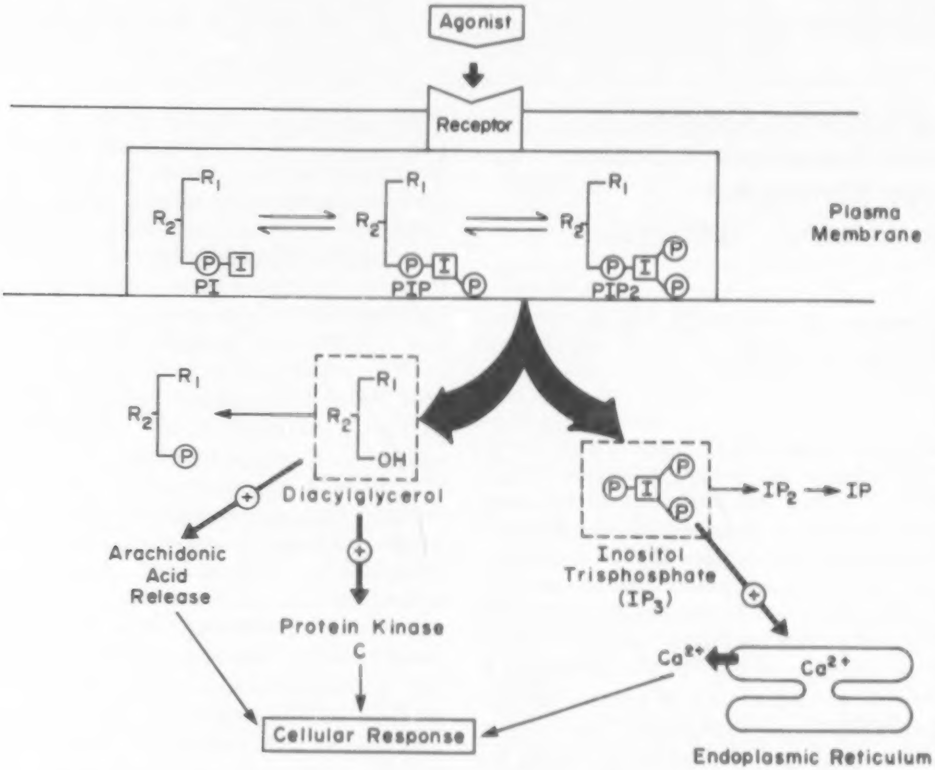

FIGURE 1. Schematic illustration of the phospholipase C/phosphoinositide hydrolysis signal cascade. Phosphatidylinositol (PI) is sequentially phosphorylated to phosphatidylinositol-4-phosphate (PIP) and then to phosphatidylinositol-4,5-bisphosphate (PIP2) by specific kinases. Agonist interaction with membrane receptors leads to the activation of phospholipase C, which catalyzes the hydrolysis of PIP2 to form inositol-1,4,5-trisphosphate (IP3) and diacylglycerol. Pathways of inactivation and second messenger functions are shown.

gested that 5HT also activates phosphoinositide hydrolysis in mammalian brain. We have recently extended these studies with the aim of determining which receptor(s) mediates the 5HT phosphoinositide effect in rat brain (Conn & Sanders-Bush, 1984; 1985). For these studies, slices of cerebral cortex were prelabelled with [3H]-inositol and the method of Berridge et al. (1982) was used to measure the accumulation of [3H]-inositol-1-phosphate (IP) as an index of the hydrolysis of radiolabelled phosphoinositides. IP is formed by the sequential dephosphorylation of IP3 to IP2 and then to IP (Figure 1). Further metabolism of IP is prevented by the addition of lithium, which amplifies the response and makes it possible to study 5HT stimulated phosphoinositide hydrolysis in brain which has a relatively weak signal.

The addition of increasing concentrations of 5HT to prelabelled cortical slices results in the accumulation of increasing amounts of IP (Figure 2). The response is maximum at 10 µM and has an EC50 value of 1 µM. A number of 5HT agonists, including quipazine, MK212, and 5-fluorotryptamine, stimulate phosphoinositide hydrolysis, but the selective 5HT-1 agonist, 8-hydroxy-2-(di-N-propylamino)tetralin, is inactive. Concentration-effect studies of several 5HT agonists showed that the EC50 values and the rank order of potencies at stimulating phosphoinositide hydrolysis in cerebral cortex agree with their potencies at the 5HT-2 binding site (Conn & Sanders-Bush, 1985). Furthermore, a number of 5HT-2 antagonists, including spiperone, ketanserin, LY 53857, pizotifen, pipamperone, and cinanserin, block 5HT ac-

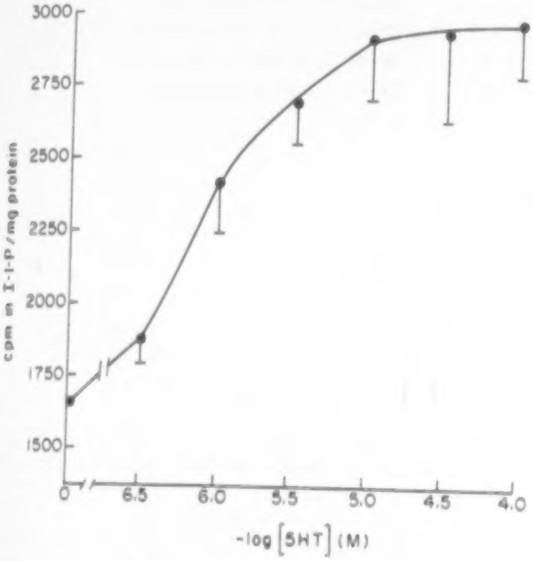

FIGURE 2. 5HT stimulated phosphoinositide hydrolysis in rat cerebral cortex. Cortical slices were prelabelled by incubating with [3H]-inositol. Increasing concentrations of 5HT were added and the release of [3H]-inositol phosphate (IP) was measured as described in Conn and Sanders-Bush (1985). Values plotted are means ± SEM for three determinations.

tivation of phosphoinositide hydrolysis in cortical slices (Conn & Sanders-Bush, 1984; 1985; Kendall & Nahorski, 1985). In order to obtain an estimate of the absolute affinity (K_d) of antagonists for the phosphoinositide hydrolysis linked receptor, concentration-response curves of 5HT's effect were measured in the presence of increasing concentrations of antagonist, as illustrated in Figure 3 for ketanserin. Dose ratios were determined and analyzed by the method of Arunlakshana and Schild (1959). The slope of the Schild plot (inset, Figure 3) is not different from unity, which suggests that ketanserin is a simple competitive antagonist of the phosphoinositide hydrolysis linked receptor. The pA_2 value of ketanserin is −7.93, corresponding to an estimated K_d of 12 nM, which is consistent with the K_d value (3 nM) of [3H]-ketanserin for the 5HT-2 binding site when determined in the presence of physiological salts. A number of other antagonists were analyzed in this manner and for those that gave results consistent with competitive antagonism, K_d values were determined. A plot of the K_d values determined by Schild analyses versus K_i values at the 5HT-2 binding site is linear (Figure 4). Regression analysis showed a significant correlation between the potencies of these drugs at inhibiting 5HT stimulated phosphoinositide hydrolysis and at inhibiting the binding of [3H]-ketanserin to the 5HT-2 site (correlation coefficient = 0.99; $p < 0.001$). Furthermore, antagonists of H-1 histaminergic, alpha-adrenergic, and cholinergic muscarinic receptors do not block the effect of 5HT, which suggests that these receptors are not involved in this response. Based on these data, we hypothesized that 5HT stimulated phosphoinositide hydrolysis in rat cerebral cortex is linked to the 5HT-2 binding site. However, the finding that activation of a given receptor stimulates phosphoinositide hydrolysis does not necessarily mean that the receptor is directly linked to phosphoinositide hydrolysis. The phosphoinositide hydrolysis response to certain agonists is secondary to receptor mediated neurotransmitter release (Bone & Michell, 1985) or to arachidonate metabolism (Rittenhouse, 1984). We have shown, however, that the 5HT-2 mediated phosphoinositide hydrolysis response in cerebral cortex is not dependent upon either of these indirect mechanisms (Conn & Sanders-Bush, 1986). Taken together, our studies in brain suggest that the 5HT-2 binding site is a functional receptor which utilizes phosphoinositide hydrolysis as its transducing mechanism. Studies of 5HT stimulated phosphoinositide hydrolysis in two peripheral tissues, platelets (deChaffoy de Courcelles et al., 1985) and aorta (Roth et al., 1984), are consistent with this conclusion.

Studies of the actions of trifluoromethylphenylpiperazine (TFMPP) and *m*-chlorophenylpiperazine (mCPP) on the 5HT-2 linked phosphoinositide hydrolysis system in the cerebral cortex have yielded some surprising findings. These compounds are generally thought to be agonists at all central 5HT receptors with which they interact. However, the efficacy at the various 5HT receptor subtypes has not been rigorously tested. Using the cortical phosphoinositide hydrolysis system, we have characterized the actions of these as well as other piperazines at central 5HT-2 receptors. Quipazine and MK-

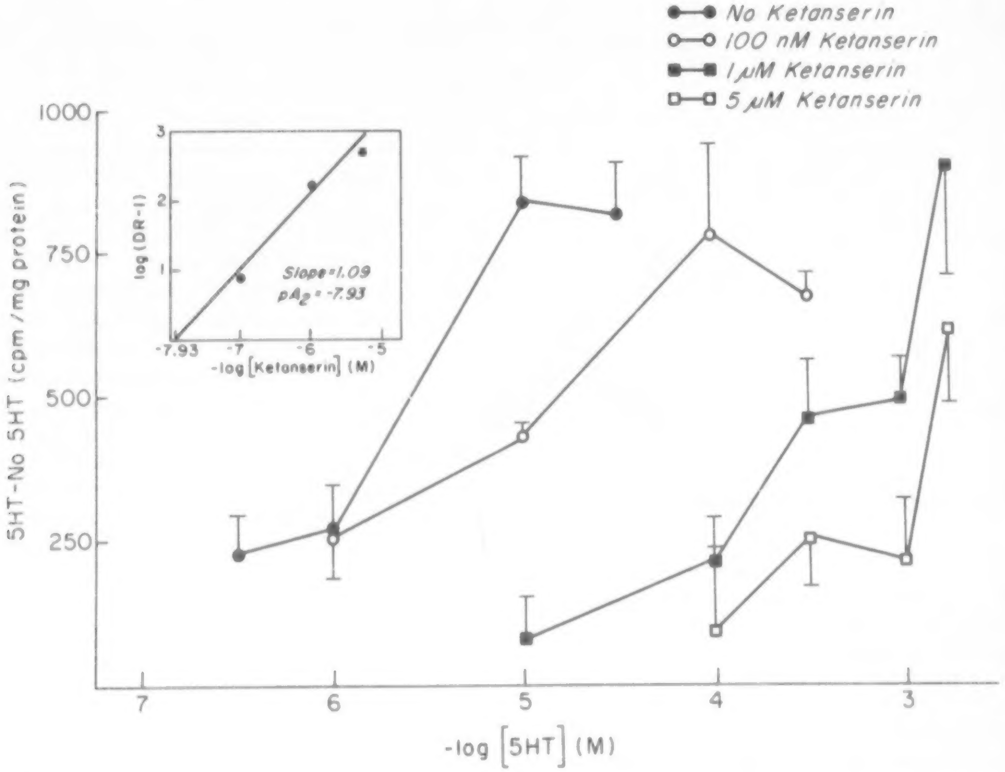

FIGURE 3. Schild analysis of ketanserin's antagonism of 5HT stimulated phosphoinositide hydrolysis in cortical slices. 5HT concentration response curves were generated in the presence of increasing concentrations of ketanserin. Inset shows the Schild plot of the same data. The dose ratio (DR) was calculated by dividing the concentration of 5HT needed to elicit a response of 600 cpm/mg of protein in the presence of ketanserin by the concentration of 5HT needed to elicit the same response in the absence of ketanserin. The pA2 (log K) value was obtained by extrapolation of the line to the *x*-axis. Each point represents the mean of two separate experiments, each done in triplicate. Vertical bars represent the SEM. Reproduced with permission from Conn and Sanders-Bush (1985).

212 function as partial agonists at these receptors. In contrast, TFMPP and mCPP fail to stimulate phosphoinositide hydrolysis at concentrations which completely inhibit the response to 5HT (Figure 5). Concentration-effect studies show that these drugs decrease 5HT's EC50 value without changing the maximum response. Thus, TFMPP and mCPP act as pure antagonists of the 5HT-2 receptor. This finding is consistent with the report that these drugs antagonize the contractile effects of 5HT in vascular smooth muscle (Cohen & Fuller, 1983), a response which is clearly mediated by the 5HT-2 site (Cohen et al., 1981). Since it is unlikely that responses to 5HT which are mimicked by mCPP and TFMPP are mediated by the 5HT-2 binding site, these compounds will be useful in future studies aimed at determining which 5HT receptor subtype mediates different central effects of 5HT.

5-HT-stimulated phosphoinositide hydrolysis in subcortical regions of rat brain is apparently mediated by mechanisms other than activation of the 5HT-2 receptor (Janowsky et al., 1984; Conn & Sanders-Bush, 1985), but the pharmacology of these effects has not yet been worked out. We have recently identified a unique 5HT receptor in the choroid plexus which is coupled to phosphoinositide hydrolysis (Conn et al., 1986). The effect of 5HT on IP formation in choroid plexus (5-fold stimulation, Figure 6) is much larger than in cerebral cortex (2-fold stimulation,

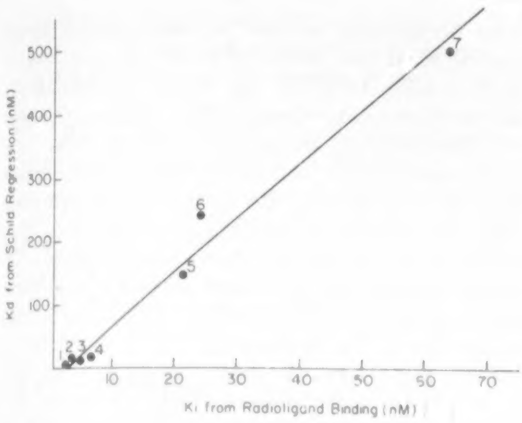

FIGURE 4. Correlation between inhibition of 5HT stimulated phosphoinositide hydrolysis and inhibition of [^{3}H]-ketanserin binding to the 5HT-2 site. The K_d values at the phosphoinositide hydrolysis linked receptor in cerebral cortex were determined by Schild analyses as described in the text. K_i values at the 5HT-2 binding site were determined by competition for 0.6 nM [^{3}H]-ketanserin binding to cortical membranes as described in Conn and Sanders-Bush (1985). 1. spiperone; 2. ketanserin; 3. pizotifen; 4. mianserin; 5. cinanserin; 6. trazodone; 7. promethazine.

Figure 2). Furthermore, the potency of 5HT is about tenfold higher in the choroid plexus. With such a robust signal in choroid plexus, it was possible to follow the time course of the formation of all three inositol sugars (Figure 7). Both IP3 and inositol bisphosphate (IP2) increase early and peak at about 5 minutes. These data demonstrate that PIP2 hydrolysis is activated by 5HT, but do not exclude the possibility that the hydrolysis of the other phosphoinositides is also increased since the three sugars increase simultaneously. The finding that the affinity of 5HT at the choroid plexus receptor (EC50 = 46 nM) is much higher than at the cerebral cortex 5HT-2 receptor (EC50 = 1000 nM) suggests that different receptor sites may mediate these effects. We therefore compared the pharmacology of the response in choroid plexus with the pharmacology of the 5HT-2 binding sites. Furthermore, the recently described 5HT-1C binding site is highly localized in the choroid plexus (Pazos et al., 1984; Yagaloff & Hartig, 1985), so the possibility that this site might mediate the effects of 5HT in this tissue was examined. The K_i value of 5HT at competing for the 5HT-1C binding site (94 nM) is similar to its EC50 at the phosphoinositide-linked receptor in choroid plexus, but not in cerebral cortex. Furthermore, the rank order and absolute potencies of antagonists in blocking phosphoinositide hydrolysis and 5HT-1C binding are in excellent agreement (Table 1). Based on the pharmacological similarity of the phosphoinositide hydrolysis response and the 5HT-1C binding site, we have concluded that the 5HT-1C binding site on choroid plexus epithelial cells is a functional receptor

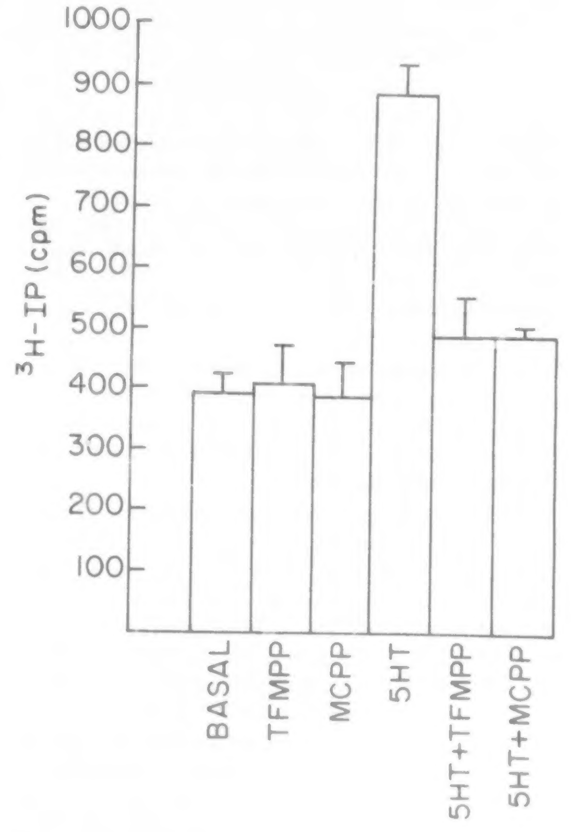

FIGURE 5. Antagonism of 5HT stimulated phosphoinositide hydrolysis by piperazines. Prelabelled rat cerebral cortical slices were incubated with 25 μM concentrations of trifluoromethylphenylpiperazine (TFMPP) or m-chlorophenylpiperazine (mCPP) in the presence or absence of 5 μM 5HT. The piperazines had no effect on the basal release of [^{3}H]-IP, but blocked the stimulatory effect of 5HT.

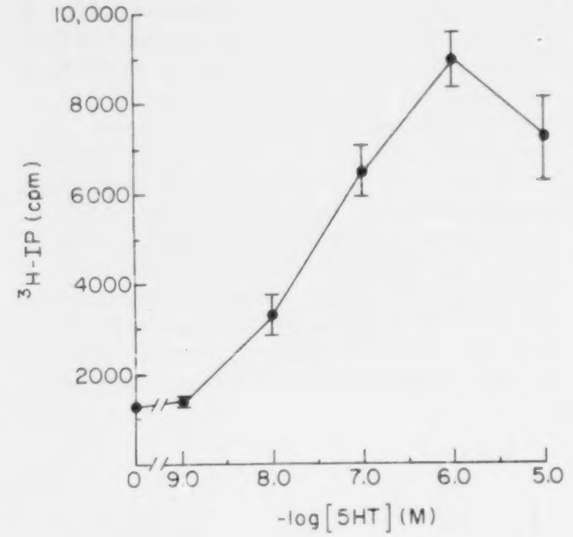

FIGURE 6. 5HT stimulated phosphoinositide hydrolysis in rat choroid plexus. Individual whole choroid plexus were prelabelled by incubating with [^{3}H]-inositol. Increasing concentrations of 5HT were added and release of [^{3}H]-inositol phosphate (IP) was measured as described in Conn et al. (1986). Values plotted are means ± SEM for three determinations.

which is linked to phosphoinositide hydrolysis. It remains to be determined if this receptor mediates any of the known physiological effects of 5HT, such as inhibition of CSF production (Maeda, 1983).

The "selective" 5HT-2 antagonist, ketanserin, has a moderately high affinity for the 5HT-1C receptor (Table 1). Frequently, the finding that a single dose of ketanserin blocks a response to 5HT is taken as evidence that the response is mediated by the 5HT-2 receptor. However, caution should be taken in making such a conclusion since the 5HT-1C receptor is also blocked by ketanserin. Mianserin, another antagonist with selectivity for the 5HT-2 versus the 5HT-1A and 5HT-1B sites, has equal affinity for the 5HT-1C (Table 1) and the 5HT-2 sites (Figure 4). Spiperone, on the other hand, distinguishes between 5HT-1C and 5HT-2 sites with more than three orders of magnitude difference in its affinities for the two sites. It remains to be determined if other "selective" 5HT-2 antagonists remain selective when evaluated at this new receptor site.

In summary, evidence has accumulated that at least two 5HT receptor subtypes, the 5HT-2 and the 5HT-1C sites, are linked to phosphoinositide hydrolysis. Although the pharmacological properties differ, there are many similarities between these two receptor sites. It remains to be determined whether these receptors are different proteins or the same gene product with posttranslational modifications or different physical environments which are responsible for the different properties. The availability of *in vitro* functional correlates of these binding sites has permitted a more precise classification of the actions of drugs. Obviously, binding studies do not differentiate whether drugs bind as agonists or as antagonists; such classifications depend on functional analyses. There is a tendency, however, to categorize drugs at all 5HT receptor subtypes as agonists or antagonists based on functional studies of a single subtype. Our finding that TFMPP and mCPP, drugs which are commonly considered to be 5HT agonists, actually function as pure antagonists of 5HT-2 receptors illustrates the need for functional studies of specific 5HT receptor subtypes.

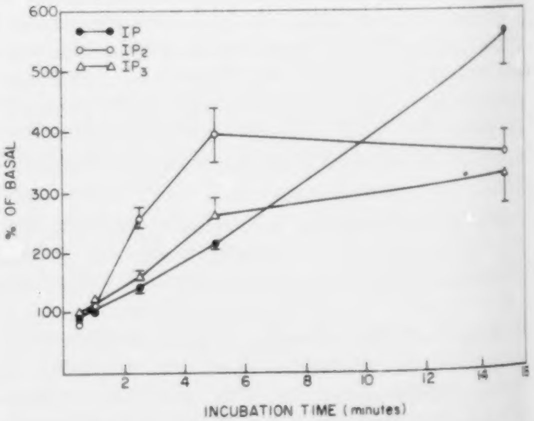

FIGURE 7. Time course of the formation of inositol sugars after the addition of 5HT. Individual choroid plexus were prelabelled with [^{3}H]-inositol. 5HT (10 µM) was added at time zero and the incubation was continued for the indicated times. The levels of radioactive IP, IP2, and IP3 were measured after purification by anion-exchange chromatography (Berridge et al., 1982). Values are presented as percent of basal levels of sugars and are mean ± SEM of 5 to 6 determinations.

TABLE 1. K_d Values (nM) at Choroid Plexus Phosphoinositide Hydrolysis Linked Receptor and at 5HT-1c and 5HT-2 Binding Sites.

Antagonist	Response[a]	Radioligand Binding	
		5HT-2[b]	5HT-1c[c]
Mianserin	12	7	5
Ketanserin	130	3	195
Spiperone	6200	2	4600

Serotonin Receptor Subtype Agonists: Differential Effects on Sensorimotor Reactivity Measured With Acoustic Startle

Michael Davis, Ph.D.,[1] James V. Cassella, Ph.D.,[1] William H. Wrean,[1] and John H. Kehne, Ph.D.[1]

Investigating how serotonin receptor subtypes interact with behavior may be simplified by analyzing how serotonergic drugs alter a simple reflex. The acoustic startle reflex in the rat offers a number of advantages in the analysis of drug effects on behavior (cf. Davis, 1980). Startle amplitude is dependent upon the characteristics of the eliciting stimulus, allowing a non-zero baseline against which both inhibitory and excitatory drug effects can be analyzed.

Drugs can act on neurotransmitters that either mediate or modulate a simple reflex behavior. A neurotransmitter that mediates startle is one that would be released within one of the four possible synapses comprising the startle pathway (Davis et al., 1982). If 5-HT containing neurons mediate this reflex then depletion of 5-HT should eliminate startle by preventing transmission from one neuron to the next within the startle pathway. However, depletion of 5-HT does not eliminate startle (cf. Davis, 1980) indicating that 5-HT is not a mediating neurotransmitter for the startle reflex.

On the other hand, considerable evidence does indicate that 5-HT modulates the startle reflex. It is clear from Table 1, however, that treatments that affect 5-HT produce complex effects on the startle reflex. Several studies have suggested that 5-HT tonically inhibits startle, since treatments that deplete the brain of 5-HT elevate startle. For example, lesions of the dorsal and median raphe nuclei (Davis & Sheard, 1974; Geyer et al., 1976), administration of *p*-chlorophenylalanine (Conner et al., 1970; Carlton & Advokat, 1973), *p*-chloroamphetamine (Davis & Sheard, 1976), or 5,7-dihydroxytryptamine (Geyer et al., 1980), or tryptophan-free diets (Walters et al., 1979) increase startle amplitude. In contrast, other studies indicate that activation of 5-HT receptors can substantially increase startle amplitude, suggesting that 5-HT is excitatory to startle. For example, increasing the levels of 5-HT by systemic administration of L-tryptophan, 5-hydroxytryptophan, or lithium (each in combination with a monoamine oxidase inhibitor) markedly increase startle (M. Davis, unpublished findings; Fechter, 1974; Svensson, 1985). Moreover, direct 5-HT agonists such as 5-methoxy-N,N-dimethyltryptamine (5-MeODMT) or 8-hydroxy-2-(di-n-propylamine) tetralin (8-OH-DPAT) increase startle substantially (Davis et al., 1980a; Svensson, 1985; Svensson & Ahlenius, 1983).

Closer examination of these data indicate, however, that 5-HT may have differential actions on startle depending upon whether it acts primarily in the forebrain or spinal cord. For example, Geyer et al. (1976) found that lesions of the median raphe nuclei depleted 5-HT in the hippocampus which correlated with increased startle. Moreover, local administration of 5-HT into the lateral ventricle (Geyer et al., 1975) or into the hippocampus itself depressed startle amplitude (Geyer,

TABLE 1. Effects of Treatments That Alter 5-HT on Startle.

Treatment	Effect	Conclusion
Raphe Lesions	Startle Increase	5-HT—Inhibitory
PCPA	Startle Increase	5-HT—Inhibitory
5,7-DHT	Startle Increase	5-HT—Inhibitory
Tryptophan Free Diet	Startle Increase	5-HT—Inhibitory
p-Chloroamphetamine	Startle Decrease	5-HT—Inhibitory
Tryptophan + MAOI	Startle Increase	5-HT—Excitatory
5-HTP + MAOI	Startle Increase	5-HT—Excitatory
Lithium + MAOI	Startle Increase	5-HT—Excitatory

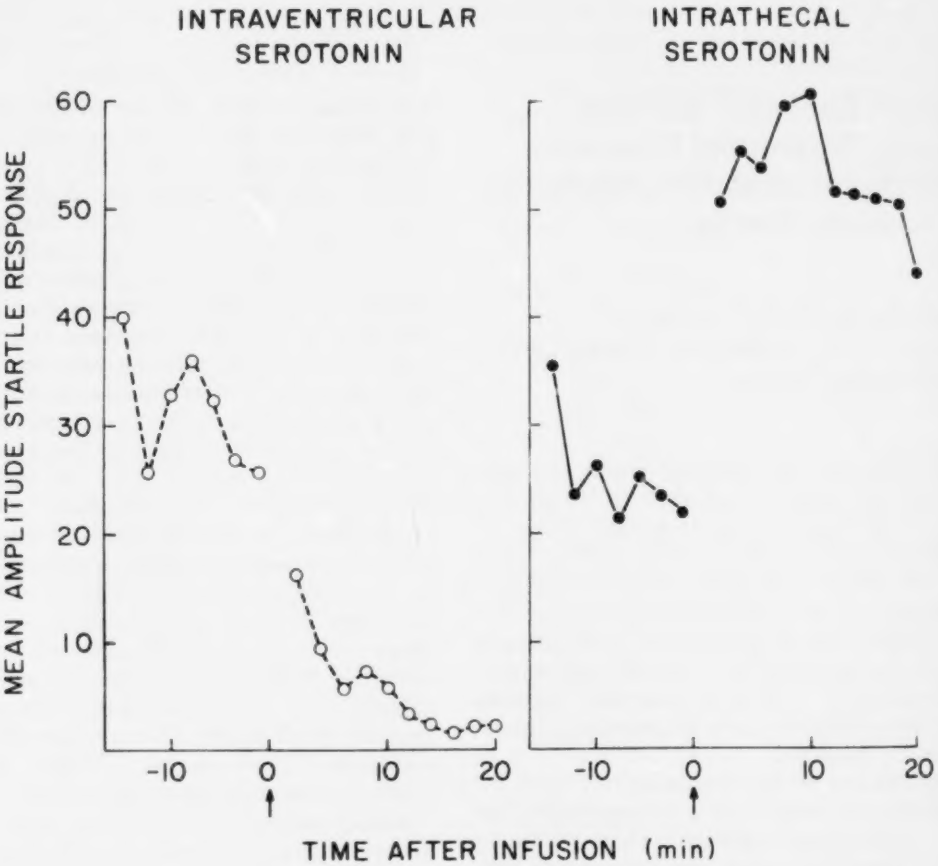

FIGURE 1. Mean amplitude startle over 2-min periods before and after infusion (arrow) of 200 μg of serotonin into the lateral ventricle (left panel) or onto the spinal cord (right panel). Reproduced with permission from Davis et al., 1980b, *Science*, copyright 1980, American Association for the Advancement of Science.

1975). On the other hand, treatments that increase startle by elevating 5-HT also produce a characteristic "serotonin syndrome," which involves structures in the brainstem and spinal cord (Jacobs & Klemfuss, 1975). Therefore it is possible that 5-HT might increase startle by actions in the spinal cord but depress startle via actions in the forebrain.

Effects of Intraventricular or Intrathecal 5-HT on Startle

To test forebrain-inhibitory and spinal-excitatory effects of 5-HT, rats were implanted with either intraventricular or intrathecal catheters, allowing for the infusion of drugs into the forebrain or spinal cord, respectively (Davis et al., 1980b). One week later all rats were injected intraperitoneally (ip) with 25 mg/kg pargyline (to retard the degradation of 5-HT) and then tested for startle before and after infusion of 200 μg of 5-HT. Figure 1 shows that 5-HT depressed startle after intraventricular administration, but increased startle after intrathecal administration. Figure 2 shows that each of these effects was directly related to the amount of 5-HT infused.

Taken together these data suggest that 5-HT depresses startle by actions in the forebrain but enhances startle by actions in the spinal cord. These findings are consistent with electrophysiological data indicating that 5-HT generally has a depressant action in a number of forebrain structures including the hippocampus (e.g., Haigler & Aghajanian,

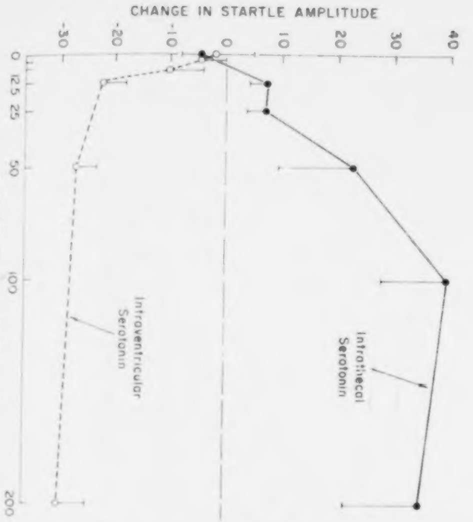

FIGURE 2. Mean change in startle, computed as the mean amplitude of startle during the 20-min period after infusion minus the mean amplitude of startle during the 15-min period before infusion, for each dose of serotonin infused onto the spinal cord (intrathecal) or into the lateral ventricle (intraventricular). Vertical bars represent the standard error of the mean. Reproduced with permission from Davis et al., 1980b, *Science*, copyright 1980, American Association for the Advancement of Science.

1974). In contrast, 5-HT facilitates motor neuron excitability (e.g., McCall & Aghajanian, 1979; White & Neuman, 1980), which may account for its excitatory effects on startle after intrathecal administration, since the motor neurons involved in startle are located in the spinal cord.

Effects of Systemically Administered 5-HT Agonists on Startle

Recent evidence indicates that 5-HT$_1$ receptors may be differentiated into 5-HT$_{1A}$ and 5-HT$_{1B}$ receptor subtypes (Nelson et al., 1981; Pedigo et al., 1981; Schellman et al., 1984). To test the possibility that the differential effects of 5-HT on startle result from actions of 5-HT at different 5-HT$_1$ receptor subtypes, we compared the effects on startle of the selective 5-HT$_{1A}$ agonist 8-OH-DPAT (Doods et al., 1985; Middlemiss & Fozard, 1983; Peroutka, 1985) with those of 1-(m-chlorophenyl) piperazine (mCPP) which along with other short-chain phenylpiperazines, has some specificity for 5-HT$_{1B}$ receptor subtypes (Asarch et al., 1985; Sills et al., 1984). In these experiments 80 rats were matched into 8 groups of 10 animals each so that each group had equivalent baseline startle levels. Two days later, each group was tested following ip injection of one of four doses of 8-OH-DPAT (0.15, 0.63, 2.50, or 10.0 mg/kg) or one of four doses of mCPP (1.25, 2.5, 5.0, or 10.0 mg/kg). Within each group, half the rats were injected with the drug on their first test day, while the other half received saline. Immediately after testing, all rats were presented with the first of 120 startle stimuli at a 20-sec interstimulus interval (i.e., 40 min of testing). Two days later, these test procedures were repeated, except rats previously injected with the drug were now injected with saline and vice versa. Hence each rat served as its own control with respect to the drug vs. saline, while drug dosage varied between groups.

Figure 3 shows that 8-OH-DPAT markedly increased startle almost immediately after injection (left panel), and that the magnitude of the effect was directly related to the dose of 8-OH-DPAT (right panel). An overall analysis of variance indicated a highly significant excitatory effect of 8-OH-DPAT ($p < .001$) which was dose dependent ($p < .005$). In contrast, Figure 4 shows that mCPP decreased startle immediately after injection (left panel) and that this depressant effect was directly related to the dose of mCPP (right panel). An overall analysis of variance indicated a significant depressant effect of mCPP ($p < .001$) that was dose dependent ($p < .05$).

Effects of 5-HT$_{1A}$ or 5-HT$_{1B}$ Agonists Given Intraventricularly or Intrathecally on Acoustic Startle.

The systemic data indicate that the 5-HT$_{1A}$ agonist 8-OH-DPAT increases startle whereas the 5-HT$_{1B}$ agonist mCPP depresses startle. Since 5-HT in the spinal cord elevated startle and 5-HT in the forebrain depressed startle, it is likely that excitatory effects of 8-OH-DPAT following systemic administration might result from actions in the spinal cord, whereas the depressant effects of systemically administered mCPP might result from actions in the forebrain. To test this hypothesis,

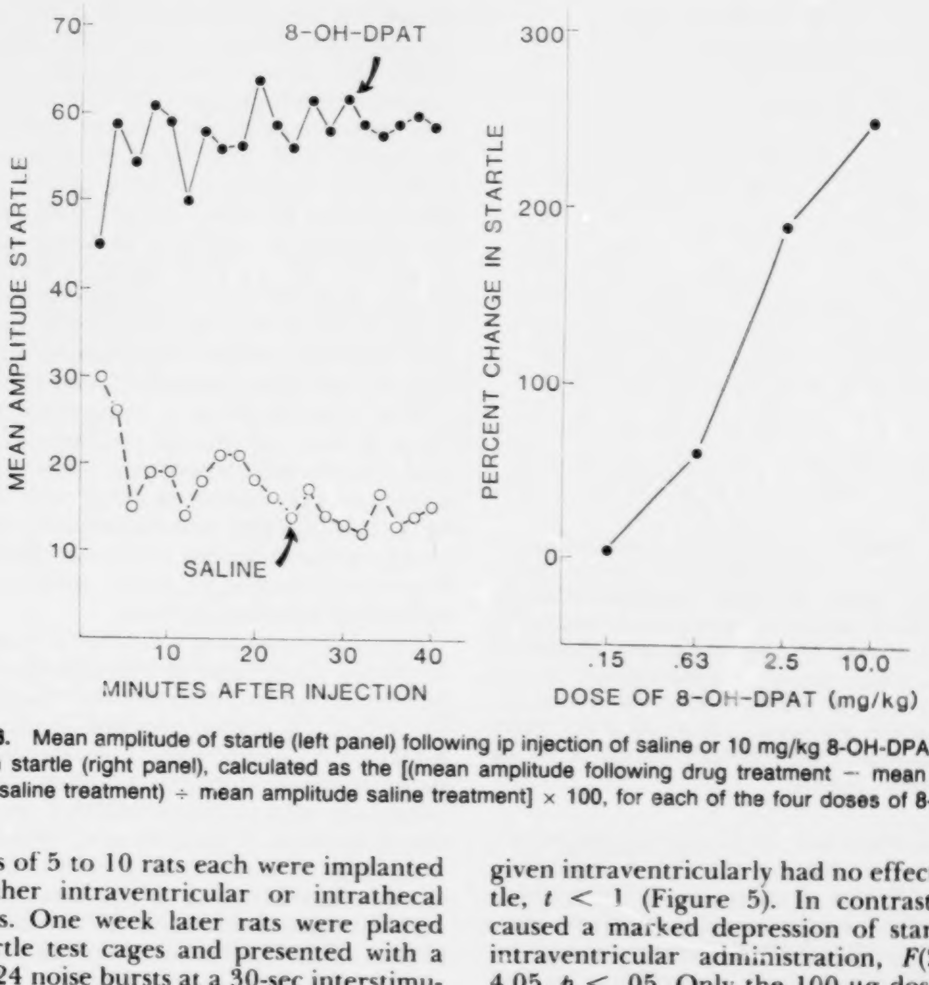

FIGURE 3. Mean amplitude of startle (left panel) following ip injection of saline or 10 mg/kg 8-OH-DPAT. Percent change in startle (right panel), calculated as the [(mean amplitude following drug treatment − mean amplitude following saline treatment) ÷ mean amplitude saline treatment] × 100, for each of the four doses of 8-OH-DPAT (ip).

8 groups of 5 to 10 rats each were implanted with either intraventricular or intrathecal catheters. One week later rats were placed into startle test cages and presented with a total of 24 noise bursts at a 30-sec interstimulus interval. The rats were then removed and infused with either 8-OH-DPAT or mCPP, using different groups of rats for different doses. Immediately thereafter the rats were returned to the test cages and presented with the first of 60 noise bursts at a 30-sec interstimulus interval (i.e., 30 min of testing).

Figure 5 shows the change in startle amplitude from the pre-infusion to the post-infusion period for the various groups. Overall analysis of these difference scores revealed that 8-OH-DPAT markedly increased startle after intrathecal administration, $F(2,17) = 6.07$, $p < .01$. Both the 50 µg and 100 µg doses significantly increased startle relative to vehicle, $t(12) = 2.13$, $p < .05$ and $t(12) = 4.26$, $p < .001$, respectively. On the other hand, even the highest dose of 8-OH-DPAT given intraventricularly had no effect on startle, $t < 1$ (Figure 5). In contrast, mCPP caused a marked depression of startle after intraventricular administration, $F(2,19) = 4.05$, $p < .05$. Only the 100 µg dose significantly depressed startle relative to vehicle, $t(11) = 2.56$, $p < .05$. Although mCPP tended to depress startle after intrathecal administration (Figure 5), this effect was not statistically significant, $t(11) = 1.16$, $p > .10$).

Summary and Future Directions

Figure 6 summarizes our present understanding of the way in which 5-HT modulates sensorimotor reactivity measured with the acoustic startle reflex. Activation of 5-HT$_{1B}$ receptors in the forebrain appears to depress startle. At the present time we do not know where these receptors might be located. As mentioned earlier, local administration of 5-HT into the hippocampus depressed startle (Geyer, 1975). However, the hippocampus

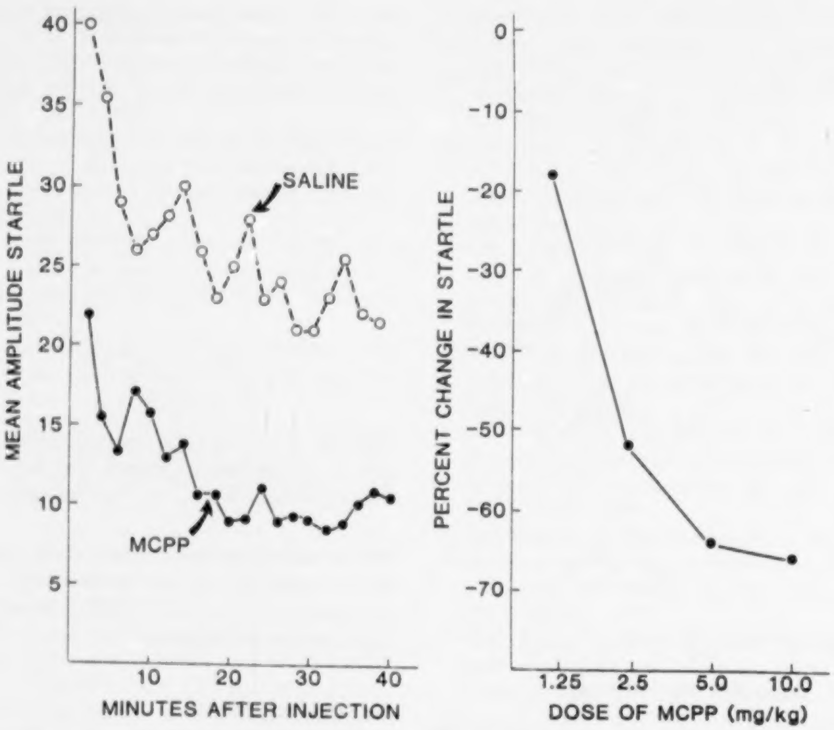

FIGURE 4. Mean amplitude of startle (left panel) following ip injection of saline or 2.5 mg/kg mCPP. Percent change in startle (right panel), calculated as the [(mean amplitude following saline treatment − mean amplitude after mCPP treatment) ÷ mean amplitude saline treatment] × 100, for each of the four doses of MCPP (ip).

contains predominantly the 5-HT$_{1A}$ receptor subtype, whereas the caudate nuclei contains a much higher density of 5-HT$_{1B}$ receptors (Deshmukh et al., 1983; Pazos & Palacios, 1985). Future studies comparing the effects of local infusion of selective 5-HT agonists into forebrain areas containing different densities of 5-HT$_{1A}$ and 5-HT$_{1B}$ receptor subtypes might determine the location of the 5-HT$_1$ receptor subtype that mediates the depressant effect on startle.

Activation of 5-HT$_{1A}$ receptors in the spinal cord increases the amplitude of the startle reflex. Electrophysiological studies indicate that 5-HT increases the response of motor neurons to excitatory input (McCall & Aghajanian, 1979; White & Neuman, 1980). Hence the excitatory effects of intrathecal 5-HT or 8-OH-DPAT may result from facilitating the response of motor neurons in the spinal cord to the afferent volley initiated by the startle-eliciting stimulus. Our behavioral data suggest that 5-HT$_{1A}$ agonists might be especially effective in facilitating the response of motor neurons when measured electrophysiologically.

Thus far we have not systematically investigated whether different 5-HT antagonists preferentially block the excitatory effects of 8-OH-DPAT vs. the inhibitory effects of mCPP on startle. Metergoline has been reported to antagonize the depressant effects of mCPP on locomotor activity (Lucki et al., 1984) whereas it does not block the excitatory effects of 8-OH-DPAT on startle (Svensson, 1985). Thus it is possible that metergoline might show selectivity for 5-HT$_{1B}$ vs. 5-HT$_{1A}$ receptors, thereby preferentially blocking the depressant effect of mCPP on startle. On the other hand, methiothepin did block the excitatory effects of 8-OH-DPAT on startle (Svensson, 1985) although methiothepin's antidopaminergic and antinoradrenergic effects (e.g., Lloyd & Barth-

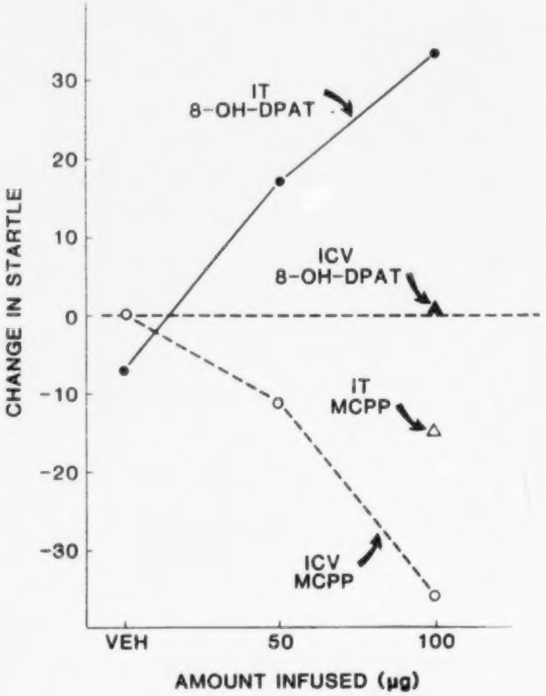

FIGURE 5. Mean change in startle, computed as the mean amplitude of startle during the 30-min period after infusion minus the mean amplitude of startle during the 12-min period before infusion, for each dose of MCPP or 8-OH-DPAT administered intraventricularly (ICV) or intrathecally (IT).

olini, 1974) may have contributed to this blockade.

Interestingly, propranolol has been reported to block the serotonin syndrome produced by L-tryptophan plus a MAOI (Green & Graham-Smith, 1976) or produced by 8-OH-DPAT (Goodwin & Green, 1985), with the 1-isomer being considerably more potent than the d-isomer. The 1-isomer is also more potent in binding to 5-HT receptors (Middlemiss et al., 1977). Previously we found that d,1-propranolol completely blocked the excitatory effect of another 5-HT$_{1A}$ agonist, 5-MeODMT, on startle (Davis, et al., 1980a). Therefore propranolol might also block the effects of either systemically or intrathecally administered 8-OH-DPAT and the 1-isomer might produce a more potent blockade than the d-isomer. In fact, the differential actions on startle of 5-HT or mCPP given intraventricularly vs. 5-HT or 8-OH-DPAT given intrathecally may provide a sensitive test procedure to evaluate the specificity of newly developed 5-HT$_{1A}$ or 5-HT$_{1B}$ receptor subtype agonists or antagonists.

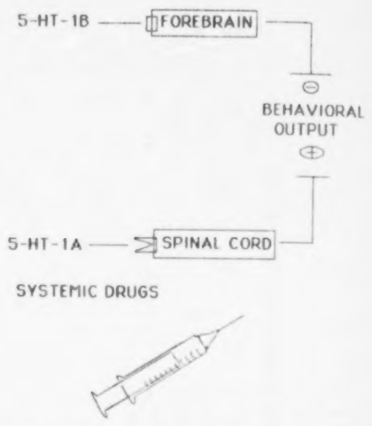

FIGURE 6. Schematic representation of behavioral effects of serotonin agonists that act on receptors in the spinal cord (5-HT$_{1A}$) or the forebrain (5-HT$_{1B}$).

Prediction of Relapse in Schizophrenia

Jeffrey A. Lieberman, M.D.,[1] John M. Kane, M.D.,[1] Stavros Sarantakos, M.D.,[1] Dominick Gadaletta, M.D.,[1] Margaret Woerner, Ph.D.,[1] Jose Alvir, Dr. P.H.,[1] and Jorge Ramos-Lorenzi, M.D.[1]

Schizophrenia is acknowledged to be a heterogeneous illness (Bleuler, 1950). Its clinical heterogeneity is manifest in the marked variability that patients within the schizophrenic syndrome have in their courses of illness (Bleuler, 1974), presentation and evolution of psychopathology (Pfohl & Winokur, 1982; Pogue-Geile & Harrow, 1984; Johnstone et al., 1978), pharmacologic treatment response (Davis, 1975; Cole et al., 1966; Klein & Davis, 1969), and vulnerability to drug side effects (Baldessarini et al., 1980). Despite this broad heterogeneity, the pharmacotherapeutic approach to treatment is surprisingly uniform.

A major deficiency in the clinical management of schizophrenia is the lack of proven methods by which to predict the subsequent course of illness and to identify patients who really require neuroleptic maintenance to prevent relapse or alternatively would remain stable for substantial periods of time without drug treatment. If such methods existed it might be possible to individualize maintenance neuroleptic pharmacotherapy for schizophrenic patients in a way that improves the benefit to risk ratio. Previous studies have suggested the utility of various measures as predictors of relapse in schizophrenia including serum or plasma prolactin (PRL) (Brown & Laughren, 1981; Zander et al., 1981) and neuroleptic levels (Brown et al., 1982; Brown & Silver, 1985), growth hormone (GH) response to apomorphine (Cleghorn et al., 1984; Mueller-Spahn et al., 1984) and behavioral response to a psychostimulant provocative test (Angrist et al., 1981; vanKammen et al., 1982; Lieberman et al., 1984).

[1] Hillside Hospital, division of Long Island Jewish Medical Center, P.O. Box 38, Glen Oaks, NY 11004.

This work was supported by PHS grants MH-38880 and MH-00537 to Dr. Lieberman. The authors wish to acknowledge the assistance of Drs. Howard Green and Steven Geisler in this project. Endocrine hormones were assayed in the laboratory of Mr. Thomas Cooper under the direction of Ms. Hana Novachenko at New York State Psychiatric Institute. Neuroleptic assays were performed in the Neuropharmacology Laboratory of Dr. Bruce Kinon, Long Island Jewish Medical Center.

The study on which we report was designed to evaluate predictors of outcome in stable outpatients with schizophrenia undergoing neuroleptic maintenance treatment.

Method

Subjects

Subjects came from the aftercare services of Hillside Hospital's department of psychiatry and met the following criteria:

1) Diagnosis of subacute, subchronic, or chronic schizophrenia or schizoaffective disorder according to Research Diagnostic Criteria.

2) Between 18 and 50 years old.

3) No history of serious neurologic disorder, endocrine disorder, or current serious medical condition.

4) A remission of their last acute episode as defined by the following items on the Schedule for Affective Disorders and Schizophrenia-Psychosis and Disorganization items (SADS-PD): a) a rating no greater than two for severity and presence of delusions (only "suspected" as being present by the rater); b) a rating no greater than two for severity and presence of hallucinations (only "suspected" as being present by the rater); c) a rating no greater than three for incoherence ("a few definite instances of impairment in understandability but they are never gross"); d) a rating no greater than three for bizarre behavior (strange behavior but not obviously "crazy"); and e) catatonic motor behavior not present.

5) Their total score on factors III, IV, and V of the Brief Psychiatric Rating Scale (BPRS) was less than 24.

6) They had been stable at their current level of remission for at least 6 months and were receiving neuroleptic maintenance treatment.

7) They were willing and able (as judged by a psychiatrist not involved with the project) to give informed consent.

Infusion Procedure

All subjects received two infusions, one of methylphenidate and one of placebo, in randomized order, 1 week apart. The drug and placebo administrations were double blind. Subjects (*N* = 11) who entered the study before a design change received a set of infusions following neuroleptic discontinuation and a 20-day washout period (42 days if the subject had been receiving fluphenazine decanoate). Those (*N* = 28) entering after the design change received a set of infusions before neuroleptic withdrawal and a set following withdrawal and the washout period.

A standardized protocol was used for all infusions (Lieberman et al., 1984).

Infusion responses were classified as positive or negative by predetermined quantitative changes in specified rating scale item scores. A positive response was defined quantitatively as an increase of at least two scale points above the thresholds of any of the critical SADS-PD items used to define remission or an eight point or more increase from the pre-infusion BPRS score of the critical items (items 4, 7, 8, 10, 11, 12, 14, and 15). (An increase of one scale point above the SADS-PD item threshold or a six point BPRS critical items increase was called a questionable response.) True positive responders were those patients who had positive change scores in responses to methylphenidate only. True negative responders were defined as having had negative responses to all infusions.

Followup

Patients were seen weekly by their treating psychiatrists, during the drug washout period and for 10 weeks following completion of the infusions. Thereafter, patients were seen biweekly. Patients were evaluated for prodromal (Herz & Melville, 1979) and formal psychopathologic symptoms at each clinic visit.

Relapse was defined as an increase of at least 2 scale points above the thresholds on any of the critical SADS-PD items used to define remission and/or a 10-point or more increase from the baseline scores of the critical BPRS items Whenever clinically possible, patients were not considered relapsed unless the symptoms persisted at this level of severity for 1 week.

Upon relapse, patients were treated with a fixed dose regimen of fluphenazine decanoate (1.0 cc IM weekly) and clinical response was evaluated for 8 weeks.

Results

Data from 34 patients were used in the analyses. The sample consisted of 21 males and 13 females with a mean (± S.D.) age of 29.1 ± 2.5 years. Twenty-three of the patients were diagnosed as having schizophrenia and 11 as having schizoaffective disorder (predominantly schizophrenic, RDC) (Spitzer et al., 1977). The patients were relatively early in their course of illness (mean ± S.D. age at onset was 20.5 ± 2.5 years), had a mean (± S.D.) of 2.8 ± 1.1 previous episodes and had achieved a level of remission sufficient for them to live in the community as outpatients (mean ± S.D. duration of remission before study entry was 109.7 ± 61 weeks) and to participate in ongoing vocational activities (e.g., a job, rehabilitation program, or school). Though stable and well functioning the sample was characterized by residual symptoms. Mean (± S.D.) item scores for the different rating scales at baseline were as follows: BPRS (all items) 1.28 ± .26; SADS-PD 1.25 ± 1.7; T & A .2 ± .4; CGI 1.94 ± .81. Sixteen of the 34 subjects had TD (overall global rating of mild on the Simpson Dyskinesia Scale). Sixteen of the 34 subjects entered the study on long acting injectable medication (fluphenazine decanoate).

Behavioral, neurologic, and endocrine responses to methylphenidate and placebo are shown in Figure 1. BPRS critical item scores were significantly increased by methylphenidate in both the on ($\bar{X}$ Δ BPRS = 1.93, t = 2.88, df = 27, p = 0.008) and off neuroleptic infusions ($\bar{X}$ Δ BPRS = 2.04, t = 2.40, df = 27, p = 0.02), but not altered by placebo. Taylor and Abrams scale scores were reduced by methylphenidate in both the on ($\bar{X}$ Δ T & A = −0.13, t = 1.93, df = 27, p = 0.06) and off neuroleptic infusions ($\bar{X}$ Δ T & A = −0.19, t = 2.58, df = 27, p = 0.02). No change was observed with placebo. Symptoms of TD and blink rate were significantly increased by methylphenidate in the on ($\bar{X}$ Δ SDS = 2.10, t = 3.68, df = 18, p = 0.002; $\bar{X}$ Δ blinks = 10.7, t = 2.45, df = 20, p = 0.02); and off ($\bar{X}$ Δ SDS = .380, t = 4.61, df = 14, p = 0.0005; $\bar{X}$ Δ blinks = 13.5, t =

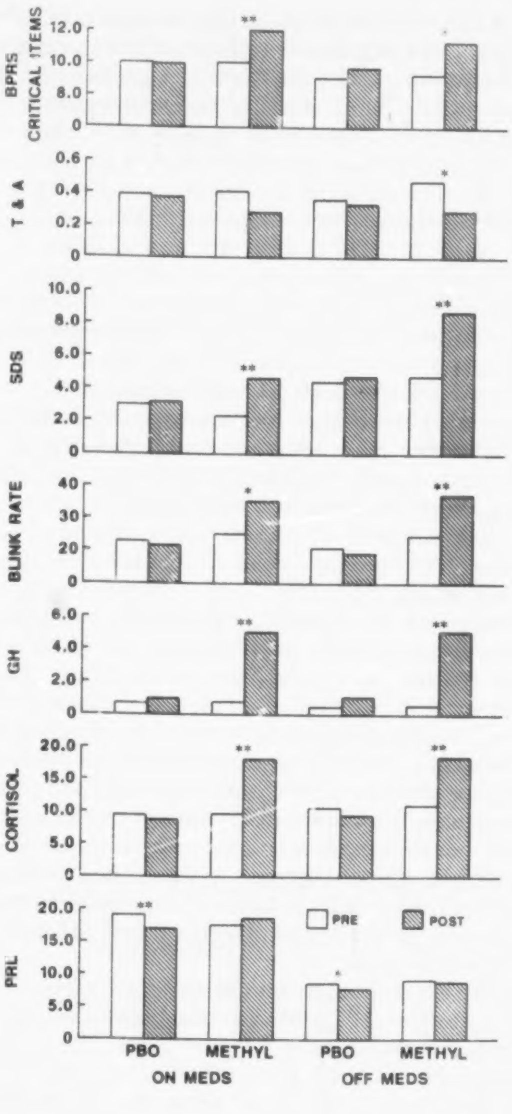

FIGURE 1. Behavioral (BPRS Critical Items Score, Taylor and Abrams Score), neurologic (tardive dyskinesia rating scale score and blink rate), and endocrine (prolactin, growth hormone, and cortisol levels) responses to infusions with placebo and methylphenidate while on and off neuroleptic medications. (* $p < .05$. ** $p < .01$.) There were no significant main effects for neuroleptic treatment or significant interactions on any of these measures. Significant methylphenidate effects were seen for BPRS critical items (F = 8.70, df = 17, p = .009), SDS (F = 36.10, df = 8, p = .00), PRL (F = 5.14, df = 18, p = .04), GH (F = 19.09, df = 16, p = .00), and cortisol (F = 42.34, df = 11, p = .00).

3.15, $df = 16$, $p = 0.006$) neuroleptic infusions but not altered significantly by placebo. Plasma GH and cortisol were significantly increased by methylphenidate during the on neuroleptic infusion ($\bar{X}\ \Delta$ GH $= 4.38$, $t = 4.82$, $df = 25$, $p = 0.0001$; $\bar{X}\ \Delta$ cortisol $= 8.19$, $t = 6.67$, $df = 18$, $p = 0.0001$) and during the off neuroleptic infusion ($\bar{X}\ \Delta$ GH $= 4.79$, $t = 5.71$, $df = 23$, $p = 0.0001$; $\bar{X}\ \Delta$ cortisol $= 7.42$, $t = 5.41$, $df = 13$, $p = 0.0001$). No change was observed with placebo. Plasma PRL significantly declined during the on neuroleptic placebo infusion ($\bar{X}\ \Delta$ PRL $= -1.89$, $t = 6.15$, $df = 27$, $p = 0.0001$) and during the off neuroleptic placebo infusion ($\bar{X}\ \Delta$ PRL $= -.93$, $t = 2.61$, $df = 24$, $p = 0.02$) but was not significantly changed during either methylphenidate infusion.

For subjects who underwent all four infusions repeated measures ANOVAs were done to test for the effects of neuroleptic treatment with methylphenidate challenge on pre-post infusion change scores on the behavioral, neurologic, and neuroendocrine measures. A significant neuroleptic treatment effect would indicate differences in pre-post infusion change scores on and off neuroleptics. A significant methylphenidate challenge effect would indicate differences in response to the methylphenidate challenge compared to the placebo challenge. A significant interaction effect would indicate differential methylphenidate challenge effects on and off neuroleptics.

BPRS critical items (neuroleptic effect $F = 1.50$, $df = 17$, $p = .24$; methylphenidate effect $F = 8.70$, $df = 17$, $p = .009$; interaction $F = .06$, $df = 17$, $p = .80$): T&A (neuroleptic effect $F = 2.10$, $df = 18$, $p = .16$; methylphenidate effect $F = 1.49$, $df = 18$, $p = .24$; interaction $F = .37$, $df = 18$, $p = .55$); SDS (neuroleptic effect $F = 3.77$, $df = 8$, $p = .09$; methylphenidate effect $F = 36.10$, $df = 8$, $p = .00$; interaction $F = 3.77$, $df = 8$, $p = .09$); blink rate (neuroleptic effect $F = 1.98$, $df = 6$, $p = .21$; methylphenidate effect $F = 1.65$, $df = 6$, $p = .25$; interaction $F = .64$, $df = 6$, $p = .46$); PRL (neuroleptic effect $F = .38$, $df = 18$, $p = .55$; methylphenidate effect $F = 5.14$, $df = 18$, $p = .04$; interaction $F = 2.83$, $df = 18$, $p = .11$); GH (neuroleptic effect $F = .14$, $df = 16$, $p = .71$; methylphenidate effect $F = 19.09$, $df = 16$, $p = .00$; interaction $F = .13$, $df = 16$, $p = .72$); cortisol (neuroleptic effect $F = .00$, $df = 11$, $p = .96$; methylphenidate effect $F = 42.34$, $df = 11$, $p = .00$; interaction $F = .27$, $df = 11$, $p = .62$).

Using the criteria for behavioral response to the infusions previously described, 6 patients were classified as positive responders, 5 as questionable responders, and 23 as negative responders (Table 1). No patient had a positive or questionable response to placebo. The highest rate of positive response was found in the off neuroleptic methylphenidate infusion (19%). No patient (who had both sets of infusions) who had a positive or questionable response to the on neuroleptics infusion had a negative response off neuroleptics, while two patients who had negative responses in the on neuroleptic infusion had positive or questionable responses to the off neuroleptics infusion. Because BPRS critical item increments during methylphenidate infusions clearly differentiated between the positive and questionable responders on one hand and the negative responders on the oth-

%Positive	0	18	14	15	10	19
%Questionable	0	11	14	7	10	5

Behavioral response rates reflecting classification of patients by all infusions are shown in the first two columns. Response rates of all patients to methylphenidate infusions by neuroleptic status are shown in the third and fourth columns. The last two columns show the response rates to methylphenidate infusions when on and off neuroleptics of patients who underwent both sets of infusion procedures.

er hand, the positive and questionable responses were combined for the purposes of outcome analyses. Positive (and questionable) and negative responders were comparable on demographic and clinical measures. Positive responders had nonsignificantly higher psychopathology scores than negative responders, and had a nonsignificantly higher proportion of females (50% to 33.3%).

The 34 patients were followed for periods ranging from 1 to 52 weeks (mean 21.4, S.D. 16.6 weeks). Survival curves for patients by behavioral response class are shown in Figure 2 (top). Periods of follow-up for the positive responders ranged from 1 to 38 weeks (median 11); for negative responders it ranged from 1 to 52 weeks (median 30). A survival analysis used to compare time to relapse as a function of infusion response indicated that positive responders were likely to relapse sooner (Wilcoxon Stat = 6.41, $df = 1$, $p = 0.01$). Ten of eleven positive responders relapsed. The 10th had been assigned to active (double blind) neuroleptic treatment after exhibiting prodromal symptoms as per the study protocol. Thirteen of twenty-three negative responders have relapsed.

The sample was divided into patients with and without tardive dyskinesia (TD) using a global score of 2 (mild) on the SDS as the criterion. This is a fairly conservative measure of TD, and since patients were examined while on and off neuroleptics there could be no false negative subjects with covert TD. Patients with TD had a median survival period of 19 weeks (range 1 to 52); patients without TD had a median survival period of 32 weeks (range 1 to 52) (Figure 2, bottom). A survival analysis used to compare time to relapse as a function of TD status indicated that patients with TD relapsed sooner (Wilcoxon Stat = 4.8, $df = 1$, $p = .028$). A chi-square analysis prompted by the similarity between the behavioral response class and TD variables' relationship to outcome revealed that patients with TD were significantly more likely to have a positive or questionable methylphenidate response ($\chi^2 = 7.58$, $df = 2$, $p = .02$).

To examine the relationship of TD response and blink rate response to outcome, we dichotomized the sample at the median of the methylphenidate infusion increment in SDS scores (three scale point increase in the sum of the seven body area global items) and blink rate (7 blinks/min) and compared the survival curves (Figure 3). There was a significant relationship between TD response to methylphenidate and outcome in the off neuroleptic infusion. Patients with the greater increases in SDS scores relapsed sooner (Wilcoxon Stat = 4.0, $df = 1$, $p = .045$); and there was a close to significant trend toward earlier relapse for patients with greater blink rate increments (Wilcoxon Stat = 3.7, $df = 1$, $p = .056$).

To examine the relationship between endocrine response and outcome, the sample was divided at the median of the distribution of the dependent variable in question. Endocrine response was defined as the difference

FIGURE 2. Outcome by behavioral response classification to methyphenidate infusions (top); and for patients with and without tardive dyskinesia (bottom).

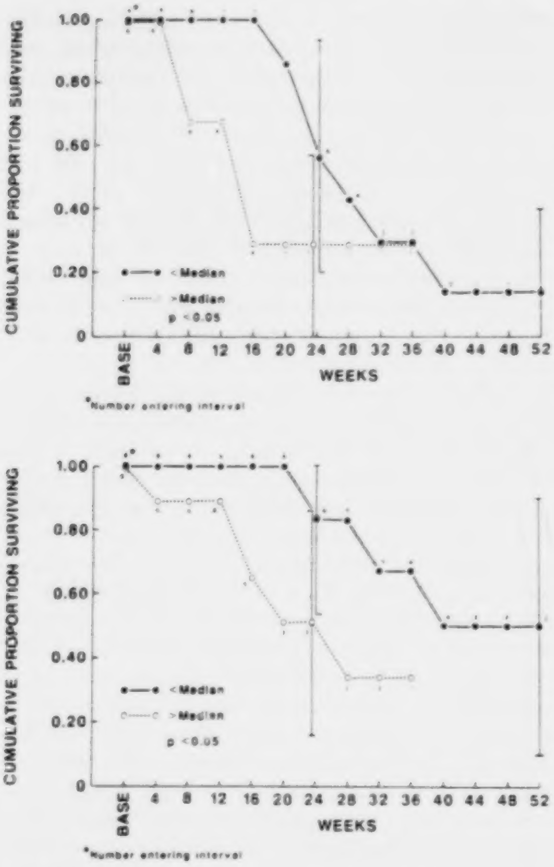

FIGURE 3. Outcome to methylphenidate infusion while off medication by tardive dyskinesia (top) and by blink rate response (bottom).

between the mean of the post-infusion values (four samples) and the mean of the pre-infusion values (three samples). Response was also defined as the difference between the maximum post-infusion values and the mean of the three pre-infusion values. Significant relationships were found between time to relapse and mean PRL response to placebo infusions both on and off neuroleptics (Figure 4), mean and maximum GH response to the methylphenidate infusion on neuroleptics and maximum GH response to the placebo infusion off medication (Figure 5). Patients whose PRL declined less than 1.4 ng/ml or increased in the placebo infusion on neuroleptics relapsed sooner (Wilcoxon Stat = 3.94, *df* = 1, *p* = .047). This did not appear to be a function of neuroleptic effects as neither basal PRL levels (on or off neuroleptics) nor neuroleptic dosage or serum neuroleptics levels correlated with relapse. Moreover, this same finding was more significant during the off medication placebo infusion. Patients whose PRL increased or declined less than .9 ng/ml relapsed more rapidly (Wilcoxon Stat = 5.88, *df* = 1, *p* = .015). Patients who had larger GH increases to methylphenidate (> 3.2 ng/ml) during the on neuroleptic infusion relapsed sooner (Wilcoxon Stat = 4.91, *df* = 1, *p* = .028); while patients who had larger GH increases to placebo (>-.2 ng/ml) during the off neuroleptic infusion relapsed sooner (Wilcoxon Stat = 7.84, *df* = 1, *p* = .005).

Discussion

The rate and pattern of relapse in this study are comparable to those previously reported in similar studies (Davis, 1975; Hogarty et al., 1974; Kane et al., 1982). The fact that specific biologic and clinical variables were significantly correlated with outcome in some cases was predicted and in other cases was unexpected. The significant relationship between behavioral response to methylphenidate was consistent with our initial hypothesis and confirms and extends the findings of Angrist et al. (1981) and VanKammen et al. (1982). It is interesting that positive and negative responders to methylphenidate were not different clinically, nor could relapse be predicted by any clinical or demographic variable. The exception to this was TD. The fact that patients with TD relapsed to a significantly greater extent than patients without TD raises the possibility of an interaction between treatment and course of illness. Comparisons of clinical characteristics between patients with and without TD, including duration of illness and number of prior episodes, however, revealed no significant differences. The fact that patients with TD were significantly more likely to be positive responders to methylphenidate suggests that these were overlapping measures. To further evaluate this, a survival analysis using a Cox proportional hazards regression model was done to assess the joint effects of TD and behavioral response classification on outcome. Both variables lost significance in this analysis, indicating that a factor common to both was affecting outcome. There are several ways to interpret this. Patients who have a certain, more severe course of illness may be susceptible to developing TD with sufficient neuroleptic exposure and sensitivity to the psychotogenic effects of methylphenidate. Another possibility is that patients who develop TD are, consequently, more sensitive to the behavioral effects of methylphenidate. The fact that TD and blink rate responses during the off neuroleptic infusion were also significantly associated with relapse provides further support for dopamine system involvement. Blink rate behavior has been described as mediated by dopaminergic systems (Stevens, 1978; Karson et al., 1982). That neuroleptic therapy diminished the apparent relationship among behavioral, TD, and blink rate response to outcome would indicate pharmacologic interference with behavior mediated by physiologic dopamine systems.

Although PRL response to methylphenidate showed no significant relationship to outcome, PRL response to placebo did. Patients with little or no decreases or absolute increases in post-placebo infusion PRL levels from pre-infusion levels were more likely to relapse. The PRL placebo response could be viewed as the secretory pattern of resting PRL over a 3-hour period, reflecting the patient's adaptation to the laboratory environment and procedure, and the diurnal rhythm of PRL (MacLeod, 1976). In this context, the lack of a decline or an increase in PRL levels could be viewed as a stress effect.

Growth hormone response to methylphenidate while patients were on neuroleptics was significantly correlated with outcome. Since this relationship was not found during the off neuroleptic methylphenidate infusion, it suggests that GH response was not a measure of endogenous physiologic dopamine activity, but possibly a functional measure of neuroleptic efficacy.

Growth hormone response to the off neuroleptic placebo infusion was significantly correlated with outcome. Davis et al. (1983) have reported that patients with schizophrenia have an irregular secretory pattern with more spontaneous peaks in secretion than is seen normally and that this may be the result of a regulatory dysfunction. This abnormal pattern was dampened by neuroleptic treatment. The increased GH response to placebo in this study may have been a reflection of these increased secretory peaks. However, when the coefficient of variation of GH values in the course of the placebo infusions was calculated, no correlation with outcome was found. Another possibility is that they also represent a stress effect.

In summary, specific biologic and clinical variables, including behavioral response to methylphenidate, presence of TD, blink rate response to methylphenidate, and anterior pituitary hormone response to methylphenidate and placebo under specific pharmacologic conditions, are associated with outcome in terms of relapse following neuroleptic withdrawal. As outcome predictors, these measures appear to have the clinically useful potential for identifying candidates for neuroleptic withdrawal and/or dose reduction treatment strategies.

Interpersonal and Pharmacologic Treatment in Schizophrenia: A Comparative Study of New Approaches

William T. Carpenter, Jr., M.D.,[1] Douglas W. Heinrichs, M.D.,[1] and Thomas E. Hanlon, Ph.D.[1]

Introduction

Current thinking regarding the interpersonal therapeutics of schizophrenia favors the use of a number of therapeutic strategies designed to address practical problems encountered by the schizophrenic patient and his (her) family. Only minimally derived from theory, these strategies tend to eschew etiologic relevance and consider pharmacological approaches as indispensable. Those receiving recent emphasis can be briefly described as follows:

1. Individual treatment aimed at establishing a close interpersonal bond between the schizophrenic patient and clinician for purposes of gathering information, offering support and encouragement, identifying the beginning of relapse, and otherwise helping the patient deal with the complex social demands that are so overwhelming for many individuals with this illness (Heinrichs & Carpenter, 1981, 1982).
2. An educational approach intended to inform patient and family regarding the nature of schizophrenia and the various treatments available and to form a link for establishing and coordinating joint therapeutic efforts (Anderson et al., 1980; Heinrichs & Carpenter, 1983).
3. Behavioral techniques aimed at reducing stress and environmental stimulation and at enhancing patient and familial coping behaviors (Wallace et al., 1980).

The present paper is a report on two open comparative trials involving the treatment of outpatient schizophrenics with two methods of drug administration and two levels of interpersonal interaction, one of which incorporated features of the above innovative strategies. The expectation in the first trial was that a targeted drug, high psychosocial intervention would be superior to a standard maintenance medication approach in terms of longer-term outcome on selected criteria (e.g., deficit symptoms). The second trial involved a comparison of standard maintenance medication with a maintenance medication approach utilizing a high level of psychosocial interaction. The expectation in this instance was that the latter approach would be superior to standard maintenance procedures on measures of deficit symptoms and overall functioning. These trials represent the preliminary phase of a research program concerned with the utility of reduced medication strategies in the treatment of schizophrenic outpatients. Because of the heuristic nature of the trials, analyses of the findings, which were *t* tests unless otherwise noted, were undertaken for exploratory rather than hypothesis-testing purposes.

General Methods

Subjects. Patients between the ages of 18 and 50 were accepted for evaluation and treatment on discharge from a psychiatric hospital unit, or less frequently, from a community clinic or practicing psychiatrist. All had had a recent psychotic episode and were in some intermediate stage of recovery. Preadmittance screening was undertaken to assure a patient cohort with a clinical diagnosis of schizophrenia. Patients who had less than 2 weeks of psychosis with no evidence of prodromal or residual symptoms and those with a longstanding, unchanging deterioration were not accepted for study. Other exclusion criteria included evidence of an organic brain disorder, recent evidence of alcoholism or clinically significant drug abuse, poor physical health, or a major medical illness requiring treatment.

---

[1] Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228.

Baseline and Treatment Procedure. Initial clinic visits were devoted to evaluation and stabilization, which generally involved the administration of neuroleptic medication for periods lasting 4 to 8 weeks. When a patient was clinically stabilized, medication was withdrawn to allow a 4-week drug-free period, during which baseline assessments were completed. Neuroleptic medication was administered only when there was an obvious need for symptom control. At the completion of the drug-free trial, the patient was randomly assigned, within sex, age, and prognostic status, to a 2-year experimental treatment course. A patient failing to complete the drug-free period on two attempts was admitted to the experimental phase while on medication.

Assessment Measures. Case history and prognostic instruments completed in the stabilization period included the *Overall Brief Psychiatric History* and the *Prognostic Scale.* Diagnostic instruments included a modified version of the *Psychiatric Assessment Inventory* (PAI) and the *Research Diagnostic Criteria* (RDC). Criterion instruments included the *Brief Psychiatric Rating Scale* (BPRS), the *Global Assessment Scale* (GAS), the *Level of Functioning Scale* (LFS), and the *Quality of Life Scale* (QLS). Criterion instruments were completed initially and at 6-month intervals by an evaluator who was independent of the treatment team. Interrater agreement on major criterion measures tended to be high, with intraclass correlations (ICC) for total scores invariably over .70 and generally within the mid .80 to mid .90 range.

Trial I Procedures and Results

Experimental Treatments

Maintenance Medication (MM). This approach was equivalent to the standard maintenance medication treatment offered to recently hospitalized schizophrenic patients by most outpatient aftercare services. Treatment was designed to provide continuous pharmacotherapy, utilizing daily chlorpromazine equivalent dosages of 300 mg or greater combined with brief visits with a pharmacotherapist on alternate weeks. Contacts with nursing personnel were also scheduled to provide medication, evaluate side effects, monitor medication use, etc. Adjustments in medication dosage level above 300 mg were made on the basis of symptom change and/or side effect manifestation. No systematic attempt was made to incorporate family members into the treatment strategy, nor were the brief clinical contacts utilized in implementing more extensive or individualized treatment plans.

Targeted Medication (TM). Patients assigned to the targeted medication approach were treated within the context of high psychosocial intervention. In this approach, medication was administered on an as-needed basis over the 2-year experimental period. Ordinarily, patients assigned to the targeted medication group remained drug-free. However, medication was initiated at moderate- to high-dosage levels on the occurrence of prodromal experiences, i.e., symptoms or signs that in the past had characteristically preceded psychotic decompensation. Medication was subsequently discontinued when the patient had returned to a stable clinical state. In effect, the targeted strategy was one of minimizing exposure to antipsychotic medication by maintaining the patient off medication during periods of clinical stability.

Psychosocial intervention consisted of assignment to a primary therapist (e.g., a psychiatric social worker) who was available for weekly sessions of approximately 45 minutes. The primary focus of these sessions was on the development of a shared view of the illness and the careful delineation of the early prodromal symptoms characteristic of the patient's prior course. The patient and therapist thereafter remained alert for the development of such symptoms so that prompt drug intervention could be made. The therapist also helped the patient identify environmental stressors and provided direction and support for minimizing their impact. This program has been described elsewhere (Carpenter & Heinrichs, 1983).

Early in the treatment course, the therapist saw the patient and family (or significant others) for six weekly sessions organized around the educational approach of Goldstein et al. (1978). The nature of the psychosis was discussed, precipitants and stressors identified, and practical suggestions for reducing stressors and their impact offered. Particular attention was paid to educating families as to the early signs of relapse and enlisting their participation in prompt intervention when these signs appeared.

Results

Sample Characteristics. The sample for Trial I consisted of 42 (20 male, 22 female) schizophrenic outpatients with a mean age of 30.7 years. Thirty-four of the patients were Black, and 8 White. Most (76%) were considered chronic (RDC) and approximately one-half were diagnosed as paranoid schizophrenic, with the remaining diagnoses fairly evenly distributed between undifferentiated and schizoaffective. Characteristics of the 2 treatment subsamples of 21 patients each are presented under Trial I in Table 1. The subsamples did not differ significantly on any of the measures involved.

With respect to initial global pathology, means for the 2 subsamples on the GAS were not significantly different, both falling in the 41 to 50 score range, reflecting "serious symptomatology or impairment in functioning that most clinicians would think obviously requires treatment or attention." Also nondifferentiating, mean LFS total scores revealed "moderate" impairment, with work functioning generally reflecting extensive unemployment and social functioning indicating limited interpersonal engagement.

Dropouts. Over the 2-year study period, 16 of the 42 study patients dropped from the study; 9 of these were MM patients and 7 TM patients. Two of the nine MM patients refused assignment to this regimen, six discontinued treatment (two after having been hospitalized), and one was noncompliant. Of the seven TM patients who failed to continue, two discontinued treatment after they were hospitalized, two were discontinued from the study while hospitalized, and three discontinued while off medication. For the two treatment groups, mean ***Prognostic Scale*** scores for dropouts were not significantly different. Further illustrating the comparability of the treatment subgroups, resulting mean prognosis scores for MM vs TM completers were nearly identical.

Medication. In examining the prescription of medication over successive phases of the treatment course, it is clear that the goal of effecting a substantial reduction in the usual prescription of medication through the use of a targeted strategy was attained (Table 2). While the average daily dosage for MM actually increased over 6-month blocks during the 2-year period, that for TM decreased, with a resulting differential treatment dose that was significant for the final 6-month period (980 vs. 183 mg). The average daily dosage over the entire 2-year period was 720 mg for MM and 196 mg for TM ($p < .05$). On the average, TM patients were on medication approximately one-third of the time (31.2%) over the course of treatment.

Outcome. By the end of the 2-year course, 11 of 21 TM patients and 9 of 21 MM patients had been hospitalized. Most of the hospitalizations for TM, i.e., 8 of 11, were during the first 6 months of treatment, while those for MM tended to occur during the second year of treatment. The differential hospitalization rate for the first 6-month period was significant.

Hospitalization did not constitute the end of a patient's involvement in the study, and most of the patients returned to the study on

Time on Medication				
TM	32.0%	29.7%	26.5%	41.0%

discharge. Additional comparative analyses of number of hospitalizations over the 2-year course therefore included both first and subsequent hospitalizations for each patient. Other than for the initial 6 months of treatment, none of these analyses yielded statistically significant results. Averages for number of hospitalizations for TM patients (N = 15 and 14) were .67 and .57 for years 1 and 2, respectively, while those for MM (N = 17,13) were .29 and .69. These figures again reflect the poorer performance for TM during the early stage of treatment. Duration of hospitalizations for completed cases in the two treatment groups was also examined (Table 3). Though MM patients tended to be hospitalized longer than TM patients (e.g., an average of 55 vs. 43 days, respectively), analyses of treatment differences with respect to duration of hospitalization were uniformly nonsignificant for every time interval examined.

Outcomes for the two groups in terms of ratings of symptoms and psychosocial functioning at both the 1- and 2-year evaluation points were virtually indistinguishable. Table 3 contains Trial I data for the 2-year period for those patients completing the program. Results for both groups were generally indicative of the maintenance of status quo with respect to levels of psychopathology, with fairly adequate symptom control being characteristic (i.e., "mild" BPRS symptoms on the average). The GAS and LFS still evidenced "need for treatment" and "moderate" impairment, respectively. Levels of psychosocial functioning, including the QLS, tended to favor TM patients, but not significantly so. The only measures approaching significance ($p < .10$) in this respect were those for an LFS measure combining the frequency and quality of social contacts and for the LFS score "Fullness of Life."

Trial II Procedures and Results

Experimental Treatments

This trial involved a comparison of the standard maintenance group of Trial I (MM) with the first 21 patients assigned to maintenance medication plus psychosocial intervention (MM+) in a subsequently conducted TM/MM+ comparison. The MM+ approach utilized in Trial II was developed to function as the control procedure for the principal comparison (to be reported later) involving targeted and maintenance medication, with psychosocial procedures held constant. The present trial intended, first, to establish the level of effectiveness for standard neuroleptic drug maintenance and, second, to determine the extent to which maintenance plus high psychosocial intervention dif-

*Higher scores indicative of better status.

fered from standard maintenance procedures with respect to outcome.

As in the standard maintenance procedure, patients assigned to MM + treatment received medication on a continuous basis, utilizing a daily chlorpromazine equivalent dosage of 300 mg as the base level. The prescription of medication, however, was performed within the context of a high level of psychosocial intervention. Besides the involvement of a primary therapist, this included the enlistment of both patients and families in the early identification of prodromal symptoms to insure prompt drug intervention and/or the reduction of stress. The criteria for both the prescription and reduction of medication were the same as those in the targeted procedure.

Results

Sample Characteristics. The sample for Trial II consisted of 42 patients (23 male, 19 female) with a mean age of 28.8 years. Twenty-nine patients were Black, 12 were White, and 1 was Oriental. Again, most (76%) were chronic and approximately one-half were diagnosed paranoid schizophrenic according to RDC, with the remaining diagnoses fairly evenly distributed between undifferentiated and schizoaffective, mainly schizophrenic. Consisting of 21 patients each, the treatment subsamples differed with respect to mean age (MM + patients younger than MM patients) and mean age at first hospitalization (MM + patients first hospitalized at a younger age than MM patients). Although proportionately more white patients were administered MM + than MM (eight vs. four), this discrepancy was not significant. As in the case of Trial I, the two subsamples did not differ with respect to initial global pathology.

Dropouts. Over the 2-year period, 3 of the 21 MM + patients dropped from the study, compared to 9 of the MM patients (*see* above). Of the 3 MM + dropouts, one refused to be placed on continuous medication, one discontinued treatment, and one moved out of the area. The difference in treatment-related dropouts (2 of 20 for MM + vs. 9 of 21 for MM) was significant ($\chi^2 = 5.63$, $p < .05$). As in the case of Trial I, lack of differentiation with respect to mean *Prognostic Scale* scores for both dropout and completer subsets was indicative of treatment group comparability.

Outcome. Over the experimental treatment course, 6 of the 21 MM + patients were hospitalized vs. 9 of 21 MM patients. Averages for number of hospitalizations for completed MM + cases ($N = 18$) were .28 and .33 for years 1 and 2, respectively, vs. .29 and .69 for MM (Table 3). Although in the expected direction, the second year difference was not significant. Average number of days hospitalized over the 2-year period for completed cases were 19 for MM + and 55 for MM ($p = .11$, Mann Whitney U Test).

Global criterion measures of psychopathology were undifferentiating with respect to treatment at both the 1- and 2-year evaluation points (Table 3). Among several measures of psychosocial functioning examined at the 2-year period, only the "Fullness of Life" item of the LFS tended to favor MM + over MM ($p = .08$).

Discussion

In the present study of the comparative efficacy of targeted vs. standard maintenance medication (Trial I), results consistently revealed that outcomes, as measured by positive symptoms, social and work performance, and negative symptom course, were essentially similar in the two treatment groups over a 2-year course of treatment. As to the need for hospitalization, the targeted drug patients required more frequent hospital admissions initially, but hospital stay was shorter, resulting in similar overall hospital utilization in the two groups over the 2-year period.

In Trial I, the targeted approach was applied to a range of schizophrenic outpatients without incurring the dire consequences often presupposed, such as extending hospitalization, disruption of living and work arrangements, harm to self and others, and progressive deterioration. Although there was little to no indication of a differentially beneficial action of TM with respect to negative symptoms, it is evident that the strategy yielded a significant reduction in exposure to neuroleptic drugs for schizophrenic patients and thereby presumably reduced the risks inherent in such exposure. (The relative incidence of untoward effects, including tardive dyskinesia, will be examined in a larger scope comparison of TM and MM + to be reported on completion of the program.)

Trial II revealed that maintenance plus psychosocial treatment was at least equivalent to standard maintenance treatment, if not superior. Results for a few key dimensions, including days hospitalized, tended to favor MM + but fell short of significance in this small sample. Also, there was indication in dropout data that MM + had more "holding" power than MM.

Some mention should be made of the sequence for implementing the psychosocial component of this research. Procedures for this component were in the early developmental stage when data were being collected on the TM sample. Although the extent to which this obscured the effectiveness of the TM approach is a matter of conjecture, it may have been a limiting factor. The MM + procedure was undertaken after 5 months experience with the psychosocial technique, during which psychosocial routines concerned with the administration of medication were perfected.

Medication, Family Psycho-Education, and Social Skills Training: First Year Relapse Results of a Controlled Study[1]

Gerard E. Hogarty, M.S.W.,[2] and Carol M. Anderson, Ph.D.[2]

Approximately 40 percent of schizophrenic patients maintained on antipsychotic medication experience a psychotic relapse in the first year following hospital discharge (Hogarty, 1984). Evidence from psychobiology and environmental psychology suggested that stimulation from the therapeutic and natural environments of vulnerable schizophrenic patients might often be sufficient to provoke underlying psychobiological deficits in the form of psychosis, even among patients who receive appropriate doses of maintenance chemotherapy.

A program of family psychoeducation/management and social skills training was developed based upon these theoretical notions as either a more direct (family psychoeducation) or less direct (social skills training) attempt to modify highly stimulating [expressed emotion (EE)] family environments (Anderson, Reiss, & Hogarty, 1986). The goal was to develop a safe and protected setting for patient and family which, in the context of maintenance chemotherapy, would lead to reduced rates of schizophrenic relapse.

Method

At hospital admission, 131 consecutively admitted patients were identified as potential candidates for this aftercare study. Following refusals and administrative terminations, 103 patients who resided in high EE households were randomly assigned to either (1) family psychoeducation and management; (2) social skills training; (3) the combination of these treatments; or (4) to a drug-maintained control group. All patients received antipsychotic medication; a majority maintained with fluphenazine decanoate. Two-thirds of the sample was male, predominantly white (81%), never married (76%), living with parent(s) (69%), and young (mean age 27). These characteristics follow upon selecting high EE subjects who live with family.

Results

For patients meeting criteria for treatment exposure, the following first year's relapse results (Hogarty et al., 1986) were observed:

1) there was a significant main effect for family psychoeducation in forestalling relapse (19% relapse);

2) there was a significant main effect for social skills training in forestalling relapse (20% relapse);

3) in the absence of evidence that treatment main effects occurred only when combined (i.e., a nonsignificant interaction), the effects of family psychoeducation and social skills training were judged to be additive (0% relapsed);

4) the international relapse rate among medicated controls was again confirmed (41% relapsed).

These results were also observed when only patients were included in the analyses who were known to be faithful medication compliers (i.e., the effect of psychosocial treatment was not simply an artifact of greater medication compliance). Further, we explored the effects of treatment on EE and subsequent relapse by means of repeated EE evaluations. We concluded that: (1) no patient relapsed in any household which changed from high EE to low EE, independent of treatment condition; (2) among households which remained high in EE, relapse continued to be elevated and was not

different among controls (42% relapsed) and those who received family psychoeducation alone (33% relapsed), or social skills training alone (29% relapsed); (3) only the combination of family psychoeducation and social skills training provided a significant prophylactic effect (0% relapsed) in households which remained high in EE.

It appeared that the family psychoeducation main effect could be explained, in part, by its relatively greater ability, as hypothesized, to lower EE in 16 of the 41 families who were treated (39%). However, lowered EE also occurred in a subsample of households not exposed to family treatment (i.e., controls and social skills training alone), where 11 of 44 households (25%) changed from high EE to low EE. An examination of patterns of EE at admission and follow-up, by treatment, for all individual relatives revealed no significant associations between the components of EE and outcome. Nor did the amount of face-to-face contact between the patient and relative explain relapse rates. Caution is suggested in making causal inferences regarding the relationship between EE and relapse. It is possible that the high EE status of households which contained a relapsed patient was due to the relapse event itself. In the absence of interim EE evaluations, it is unknown to us whether some or all of these households had, in fact, changed from high to low EE and then returned to high EE at the time of the patient's relapse. Preliminary analyses of the adjustment of non-relapsed patients suggest that better adjusted patients were found in households who changed from high to low EE. This being the case, it is possible that some families change their EE status because the patient's condition improves, rather than that lowering EE causes the better patient outcome.

Unfortunately, contrary to predictions, rates of relapse in the second post-discharge year have increased significantly. At the end of 2 years there remains a significant, but modest, main effect of family psychoeducation in forestalling relapse.

Discussion

The results of this study are essentially in agreement with those reported by Leff et al. (1982, 1985) and Falloon et al. (1982, 1985) in their studies of family treatment and medication among patients residing in high EE households. The low relapse rate of patients in families treated with psychoeducation and management strategies is consistent across studies and remains less than 10 percent at 9 months and equal to or less than 20 percent at 12 months. Relapse rates among drug treated controls at 9 months was 50 percent in the Leff et al. (1982) study and 44 percent in the Falloon et al. (1982) study. Thus, we are able to conclude that following many decades of study, there is increasing evidence that psychosocial interventions do add something more to the maintenance treatment of schizophrenic patients than drug therapy alone, at least in the first year following hospital discharge. Unfortunately, the rise in relapse rates over time indicates that important treatment challenges remain:

1) strategies are needed for recovered patients (and their families) which would sustain compliance with maintenance chemotherapy and psychosocial programs over time; and

2) more patient specific interventions need to be developed which would respond to the sources of *internal* stimulation among recovered patients, particularly as these patients move toward a fuller life beyond the clinic and family.

At the moment our greatest success seems to be in the early convalescent months when family life can be tempered and the patient trained to accommodate and respond to this protected environment. Later attempts by the recovered patient for a more complete and autonomous life beyond clinic, home, and sheltered workshop seem associated with noncompliance and/or exposure to sources of stimulation with which the patient is unable to cope.

Nicotine as a Psychoactive Drug: Anxiety and Pain Reduction, Arousal, and Appetite Regulation

Co-Chairs:

Murray E. Jarvik, M.D., Ph.D.
Brentwood VA Medical Center
Los Angeles, CA 90024

Ovide F. Pomerleau, Ph.D.
University of Michigan School of Medicine
Ann Arbor, MI 48105

Introduction

Nicotine is the principal psychoactive agent in smoking. The pharmacological actions of this drug are complex and, in some ways, paradoxical. Though highly toxic, nicotine in small doses is reinforcing, maintaining self-administration with remarkable tenacity. Though neither dramatic intoxication nor dramatic withdrawal effects are associated with chronic nicotine use, nicotine self-administration, particularly from cigarettes, occurs in nearly half of the world's adult population; no culture to which the tobacco habit has been introduced has eradicated it. Over the years, there has been some disagreement about the nature of reinforcement mechanisms in smoking. Researchers can be divided into two main camps—those who believe that the smoking habit is largely the result of psychological factors (i.e., learning and conditioning); and those who emphasize pharmacological factors (i.e., the addictive nature of nicotine). The panel reviewed research on some of the effects of nicotine that seem to provide reinforcement for smoking and attempted to integrate psychological and pharmacological phenomena.

Dr. Pomerleau reviewed research indicating pain- and anxiety-reduction from nicotine administration. He pointed out that various studies on motives for smoking and on recidivism have established a strong relationship between dysphoric mood states and smoking. He described his own research, using anxiety and cold-pressor pain as well-defined indicators of psychologically relevant nicotine activity, demonstrating antinociception and anxiety reduction after nicotine administration in minimally deprived smokers. Cold-pressor pain reduction was also observed in ex-smokers, who are no longer pharmacologically dependent on nicotine. These findings suggest that reinforcement for smoking is not exclusively the result of relief of nicotine withdrawal but also involves effects independent of the nicotine addiction cycle.

Dr. Domino reviewed animal and human research on nicotine-produced electrocortical arousal and enhanced psychological alertness. He observed that a large percentage of smokers claim that smoking helps them to think more clearly and to concentrate, thereby enhancing performance on tasks like visual surveillance and rapid information processing as well as long-term memory (recall). Animal research has demonstrated critical EEG desynchronization accompanied by waking after nicotine injection, followed by slow-wave sleep that is more profound than before nicotine administration. Other effects of nicotine include inhibition of phasic stretch reflexes and facilitation of orienting reflexes as well as biphasic effects on the cardiovascular and respiratory systems.

Dr. Grunberg reviewed animal and human research on the effects of nicotine on appetite regulation. He noted that many smokers specify control of body weight as an important reason for continuing to smoke. In fact, cigarette smokers weigh less than nonsmokers of comparable age. Recent findings in his laboratory indicate that nicotine administration is accompanied by decreased consumption of sweet-tasting substances in both animals and humans, with corresponding decreases in total caloric intake. The issue of whether this effect is attributable to reduction of hunger for carbohydrates or to modification of taste for sweet foods by nicotine administration was considered.

Dr. Jarvik integrated these themes, presenting new data on the role of enhanced alertness as a reinforcer for smoking and on postprandial smoking. He also discussed the biphasic effects of nicotine (i.e., arousal followed by calming), different responses associated with nicotine dosage/speed of administration, and the role of personality and situational variables in determining reinforcement value.

Ovide F. Pomerleau

Nicotine as a Psychoactive Drug: Anxiety and Pain Reduction

Ovide F. Pomerleau, Ph.D.[1]

Smoking is often characterized as negatively reinforced behavior—i.e., as escape from or avoidance of an aversive state of withdrawal in an addictive cycle (Russell, 1977). Withdrawal from smoking is associated with increased anxiety and pain sensitivity, disruption of performance, and various dysphoric states such as irritability (Schachter, 1978). An important implication of the addiction model of smoking is that the probability of smoking/nicotine self-administration is linked to the time since the last cigarette and the current plasma nicotine level.

A number of studies confirm basic elements of the addiction model (*see* Jarvik, 1979). Work in my laboratory (Pomerleau, Fertig, & Shanahan, 1983) comparing heavy and light smokers (using plasma cotinine as the basis for classification) found that heavy smokers: 1) took in more nicotine from research cigarettes (which were used to eliminate the confounding effects of brand preference); 2) exhibited greater physiological tolerance to nicotine (attenuated heart rate increase and skin temperature decrease per plasma nicotine increment); 3) demonstrated more nicotine withdrawal symptoms when deprived of cigarettes overnight; and 4) showed closer regulation of plasma nicotine (that is, proportionally less variation in plasma nicotine when smoking cigarettes of differing strengths)—attributes consistent with an addiction model.

The addiction model in its extreme form (e.g., Schachter, 1978) holds that the principal consequence of smoking is the relief of withdrawal symptoms created by its absence. Such a formulation has limitations as a comprehensive explanation of smoking. With the exception of the first cigarette of the day or of cigarettes smoked after an extended period of deprivation, much *ad libitum* cigarette smoking seems to be prompted by various environmental events (interoceptive or exteroceptive stimuli) that are independent of the time since the last cigarette—e.g., various dysphoric states, performance demands, etc. (*see* Pomerleau & Pomerleau, 1984). Moreover, there are no clear demonstrations of smoking withdrawal prior to *ad libitum* smoking at intervals that are representative of ordinary smoking (half an hour to an hour since the last cigarette). Even at its peak at 24 hours of deprivation, the withdrawal state is variable, idiosyncratic responses being the rule (Hatsukami et al., 1984; Shiffman & Jarvik, 1976).

Nearly half the world's adult population smokes, and even in industrial nations such as the United States, 30 percent of the population continues to smoke despite well-publicized adverse health effects and increasingly restrictive societal and legislative proscriptions. The line of experimentation described herein is an attempt to characterize some of the reinforcing stimuli for *ad libitum* smoking and to understand how nicotine, a drug that produces neither dramatic intoxication nor marked withdrawal, can control behavior so powerfully.

Behavioral responses—pain reduction and anxiety relief—were selected as representative of the reinforcing consequences of smoking, a choice supported by numerous investigations involving nicotine administration in both animals and humans (Battig, 1980; Gilbert, 1979). The choice of pain and anxiety reduction, known markers of endogenous opioid activity, was also influenced by this laboratory's demonstration of nicotine-stimulated beta-endorphin release in circulating plasma (Pomerleau et al., 1983; Seyler et al., 1986). Pain was induced using a cold pressor apparatus (immersing an arm into freezing water); anxiety was induced by having subjects attempt to solve a puzzle (a six-letter

The research was supported by National Cancer Institute grant CA 42730.

anagram) they had previously failed to complete.

In an initial set of experiments (Pomerleau et al., 1984), habitual smokers (who had smoked in excess of a pack a day for more than 5 years) served as paid subjects. Each experiment involved a screening session followed by experimental sessions with and without nicotine available. The screening sessions provided a 5-minute exposure to freezing (4.0 ± 0.5°C) water to allow subjects to set a criterion for cold pain in subsequent sessions (Experiment I) or exposure to failure at solving an (unsolvable) anagram to provide a means of inducing anxiety in subsequent sessions (Experiment II). (Subjects were told that they would receive a $10 bonus if they solved the anagram in 60 seconds or a $5 bonus if they solved it in 5 minutes.)

Subjects smoked a usual-brand cigarette half an hour before each experimental session to insure comparable, minimal levels of deprivation. In experimental sessions, subjects smoked either usual-brand cigarettes with brand markings deleted (mean nicotine content, 1.2 mg/cigarette) or zero nicotine cigarettes ("Free," International Brands, Inc., Los Gatos, CA) for 5 minutes. In Experiment I, after completion of the cigarette, subjects were exposed to freezing water for 5 minutes; pain awareness and endurance thresholds were determined, and the McGill Pain Questionnaire was administered. In Experiment II, subjects were told prior to consuming a cigarette that in 5 minutes they would have another opportunity to solve the anagram. The Spielberger State Anxiety Inventory was administered before and after completion of the cigarette.

In Experiment I, all five subjects showed increased pain awareness thresholds after they smoked a usual-brand cigarette (related-measures *t*-test; $p < .05$, one-tailed). Four of five subjects showed increased pain endurance (the fifth kept his arm immersed for the 5-minute limit in both sessions) and three of five reported decreased perception of pain (as indicated by lower scores on the McGill Pain Rating Index [PRI]; *see* Table 1). In Experiment II, all five subjects showed a greater decrease in anxiety when they were allowed to smoke their usual-brand nicotine-containing cigarette, as shown in Figure 1. [Analysis of Variance, prepost × nicotine condition; $F(1,4) = 14.38, p < .05$.]

The initial experiment left unanswered the question of whether antinociception and anxiety reduction were attributable to the smoking of a usual-brand cigarette or to the intake of nicotine. Accordingly, the findings were replicated in an additional 10 male smokers (Fertig et al., in press). The general procedure resembled that of the first experiment. Instead of smoking usual-brand cigarettes, however, subjects did the following on 4 successive days: 1) smoked two high-nicotine (2.87 mg) research cigarettes (Tobacco and Health Research Institute, Lexington, KY) 5 minutes apart (to remove the contribution of brand preference); 2) self-administered fine tobacco snuff ("Sweet Scotch" snuff, Helme Tobacco Company, Helmetta, NJ) intranasally over two 5-minute periods (to provide nicotine by a novel route of administration); 3)

smoked two zero-nicotine cigarettes (to control for smoke inhalation); and 4) sham-smoked two unlit cigarettes (to control for psychological effects and motor behavior). Nicotine and no-nicotine conditions were counterbalanced to control for order effects. Blood was withdrawn unobtrusively from the median antecubetal vein.

As shown in Figure 2, the two nicotine conditions resulted in marked increases in plasma nicotine, whereas in the no-nicotine conditions plasma nicotine decayed slightly over the 55-minute session. Table 2 presents the effects of nicotine intake on antinociception: Smoking high-nicotine cigarettes significantly increased pain awareness thresholds compared with sham-smoking [F (1,8) = 66.28, $p < .0001$], as did administration of tobacco snuff [F (1,8) = 21.5, $p < .005$]. Similar increases were found for pain endurance thresholds following high-nicotine cigarettes [F (1,8) = 21.15, $p < .005$] and following snuff [F (1,8) = 17.09, $p < .005$]. High-nicotine cigarettes also reduced significantly the perception of pain on the McGill Pain Rating Index (PRI) [F (1,8) = 7.56, $p < .05$], although snuff did not. Estimation of cold-pressor pain at its worst (Worst Pain Index; WPI) was significantly reduced (as indicated by lower scores) following the administration of snuff [F (1,8) = 8.33, $p < .05$] but not following the smoking of high-nicotine cigarettes.

In the above experiment, no observable differences in nicotine withdrawal were found in minimally deprived subjects prior to smoking nicotine or no-nicotine cigarettes, but the possibility that nicotine administration caused relief of withdrawal unrecognized by the subject could not be ruled out. In response to this ambiguity, 15 male ex-smokers (no cigarettes in the last year, as validated by the absence of detectable nicotine in plasma) were exposed to one session in which they snuffed a single dose of tobacco (about one-fourth the dose used for smokers) and another in which they snuffed an inert substance ("Postum," General Foods, White Plains, NY). As shown in Table 3, pain awareness and endurance thresholds increased and McGill scores decreased following administration of tobacco snuff, though only endur-

ance reached significance $[F\ (1,13) = 7.65,\ p < .05]$.

These studies demonstrated that antinociception was not the result of brand preference, smoking as a ritual behavior, or inhaling smoke *per se*, but rather was a consequence of nicotine intake independent of route of administration. Since smokers were minimally deprived and exhibited no significant differences on the Shiffman Withdrawal Inventory prior to the nicotine/no-nicotine conditions as compared with *ad libitum* smoking at the screening session, we infer that antinociception following smoking is not simply the result of relief of withdrawal (the simple addiction model hypothesized by Schachter, 1978). The argument is strengthened by the observation that ex-smokers, who are no longer pharmacologically dependent on nicotine and do not exhibit any withdrawal symptoms, also showed reduced pain in the nicotine condition. It should be noted, however, that in pilot studies, ex-smokers were able to take in larger doses of tobacco snuff than people who had never smoked before, suggesting that some residual tolerance (and, theoretically, some degree of withdrawal) might exist. Thus, while the above studies and previous research with nicotine-naive animals strongly support the existence of nicotine effects that are independent of relief of nicotine withdrawal, the definitive test at the human level may have to be conducted with people who have never been nicotine-dependent.

The above research, along with findings from other laboratories, has led to the formulation of a biobehavioral model emphasizing the neuroregulatory mediation of key reinforcing consequences in smoking (Pomerleau & Pomerleau, 1984). As shown in Table 4, a compilation of numerous investigations on the behavioral and subjective consequences of smoking suggests that smoking produces effects that can be seen as favorable or adaptive, at least from a short-term perspective. Salient among these effects is reduction of negative affect (e.g., anxiety relief; McKennell, 1970; Shiffman, 1982). Depending on the antecedent conditions (exteroceptive or interoceptive stimuli defining either a neutral or aversive state), these consequences can be defined as either positive or negative reinforcers. Under this formulation, various exteroceptive or interoceptive stimuli, such as demands for task performance, dysphoric states (including pain and anxiety), socializing, or even completion of a meal, serve as discriminative stimuli for smoking, setting the occasion for nicotine self-administration because in the past, smoking/nicotine intake produced temporary improvements in performance or affect. The model further proposes that in the heavy smoker, these "extra" cigarettes are superimposed on a nicotine addiction cycle in which smoking relieves aver-

sive withdrawal symptoms experienced when the inter-cigarette interval becomes sufficiently long.

The above formulation begins to provide an explanation for the remarkable strength of the smoking habit. Evidence suggests that the number of affective states or performance demands that can be modified by nicotine is quite large (Pomerleau & Pomerleau, 1984), providing a plausible explanation for the thorough interweaving of smoking into the fabric of daily life. Moreover, from the perspective of learning theory (*see* Pomerleau, 1981), the immediacy of the consequences of smoking (one quarter of the nicotine inhaled in smoke crosses the blood/brain barrier in 7 to 10 seconds) and the sheer number of repetitions (a pack a day smoker receives over 70,000 puffing reinforcements per year) can be seen as adding considerably to the persistence of the habit (Jarvik, 1979). What is needed now is systematic research directed toward elucidation of the neuroregulatory concomitants of the reinforcement of smoking, taking into account interactions between the stimulus context for smoking and its behavioral and subjective consequences.

Nicotine: A Unique Psychoactive Drug—Arousal With Skeletal Muscle Relaxation[1]

Edward F. Domino, M.D.[2]

Introduction

From a molecular point of view, nicotine has many common elements with the neurotransmitter acetylcholine (ACh). If one examines the positive and negative charges and the distance between them for both molecules, they are very similar, as shown in Figure 1.

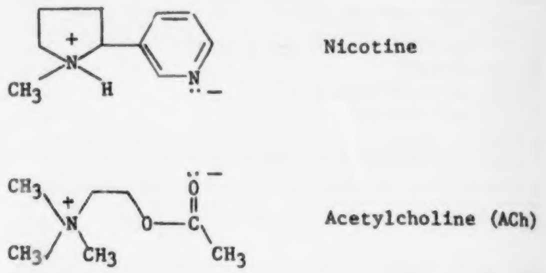

FIGURE 1. Chemical structure of nicotine and acetylcholine.

This is especially true at pH 7.4 because the pyrrolidine nitrogen of nicotine is partially ionized. Likewise, the pyridine nitrogen has two electrons that line up with the electrons of the oxygen at the esteratic site of ACh. Thus, it turns out that nicotine precisely mimics ACh from an electronic and structural point of view. This is the molecular basis of the nicotinic actions of ACh. Nicotine has an appropriate set of pKas so that at body pH of 7.4 about 69 percent is ionized at a temperature of 37°C. About 31 percent of nicotine molecules can penetrate a large variety of lipophilic membranes including the blood-brain barrier, the blood-placental barrier, etc. Since nicotine is a substance that exists both in ionized as well as un-ionized forms, it can act both extracellularly as well as penetrate various lipophilic barriers.

Multiple Actions of Nicotine

In tobacco-smoking concentrations nicotine is a remarkable psychoactive drug (Domino, 1973). A wide variety of complex stimulant and depressant effects are observed in animals and humans that involve the central and peripheral nervous, cardiovascular, endocrine, gastrointestinal, and skeletal motor systems. These heterogeneous effects are further intermingled with personality and other behavioral variables that result in self-administration, tobacco dependence, and withdrawal phenomena upon abrupt cessation of tobacco smoking. The following are among the key issues related to the pharmacology of nicotine:

1) *Nicotine Receptors.* There are multiple nicotinic receptors in the brain including very high, high, and low affinity types. Their relation to nicotinic ganglionic and skeletal muscle receptor types needs elaboration. Extensive research in the past 10 years has shown the existence of nicotinic cholinergic binding sites in the brain. Although α-bungarotoxin is a very useful ligand to study peripheral nicotinic cholinergic receptors at the neuromuscular junction, its use in labeling functional nicotinic receptors in the brain has been unrewarding. There is no question that α-bungarotoxin binding sites exist in the brain, but those sites differ from those to which nicotine binds. Some investigators have stressed the noncholinergic binding of ^{3}H-labeled nicotine, while many others have emphasized that ^{3}H-nicotine can bind to specific nicotine cholinergic receptors in the brain. This literature has been summarized in the recent publication by Shimohama et al. (1985) who have characterized two saturable

binding sites for (–)^{3}H-nicotine in human brain, one with a K_d of 8.1 and the other 86 nM, and a B_{max} of 36 and 90 fmole/mg protein, respectively. Sloan et al. (1984) have stressed that ^{3}H-nicotine binding is extremely complex, involving very high, high, and low affinity sites.

Perhaps the most unexpected findings regarding nicotinic cholinergic binding sites are those described by Schwartz and Kellar (1985). They reported that nicotine tartrate equivalent to 1 mg/kg s.c. of (–) nicotine base given *b.i.d.* for up to 21 days caused a progressive up-regulation (30–40% increase) in regional rat brain ^{3}H-ACh binding sites measured in the presence of atropine to occupy the muscarinic sites. In contrast, the binding of ^{3}H-3-quinuclidinyl benzilate (QNB) to the muscarinic sites was unaffected by the nicotine treatment. Chronic isofluorophate (DFP) administration caused the expected down-regulation of both nicotinic and muscarinic receptor binding (Russell et al., 1981; Schwartz and Kellar, 1983b). Marks et al. (1983) reported an up-regulation of ^{3}H-nicotine binding sites to continuous nicotine infusions in mice. Clarke et al. (1986) have shown that in the rat brain the autoradiographic distribution of ^{3}H-ACh and ^{3}H-nicotine are essentially identical. Therefore, up-regulation of nicotine cholinergic binding sites to chronic nicotine appears to be an established fact, at least in mice and rats. Both Marks et al. (1983) and Schwartz and Kellar (1985) have suggested a functional blockade of the nicotinic cholinergic receptors with sufficient recovery that would allow enhanced behavioral responses to low doses of nicotine within 24 hours, as has been shown behaviorally by Clarke and Kumar (1983) and Ksir et al. (1985).

London et al. (1985b) have used *in vitro* autoradiography to identify ^{3}H-nicotine binding sites in the rat brain. The most intense localization of ^{3}H-label was in the interpeduncular nucleus and medial habenula. Other nuclei of the brain showed some binding, but it was not detected in the hippocampus or the periaqueductal grey matter. The relative absence of nicotine binding in the hippocampus is surprising. Miner et al. (1985) have shown that mice sensitive to the convulsant effects of nicotine have greater α-bungarotoxin binding in the hippocampus than seizure insensitive mice.

2) *Acetylcholine Release*. In the past 23 years there has been accumulating evidence to support the hypothesis that some of the actions of nicotine are due to the release of ACh and other neurotransmitters, especially NE. Chiou and Long (1969) and Chiou (1973) obtained evidence that nicotinic cholinergic agonists including nicotine, carbachol, and 1,1-dimethyl-4-phenylpiperazinium (DMPP) release endogenous ACh from the presynaptic cholinergic nerve terminals rather than stimulating postsynaptic nicotinic receptors. This was shown using a chick nerve-muscle preparation. Chiou et al. (1970) also showed that these same nicotinic agonists could release ACh from rat cerebral cortical synaptic vesicles. Briggs and Cooper (1982) showed that nicotine and DMPP release newly synthesized ^{3}H-ACh from synaptosomes prepared from the myenteric plexus of guinea pig ileum. The release of ^{3}H-ACh was Ca^{++} dependent and was blocked by C_6 and curare. More recently, Rowell and Winkler (1984) showed that newly synthesized ^{3}H-ACh was also released from mouse cortical synapses by both nicotine and DMPP. The release of ^{3}H-ACh by nicotine was Ca^{++} dependent and was blocked by C_6. Thus there is good evidence that nicotine releases ACh by a presynaptic mechanism. In contrast, presynaptic muscarinic receptors (mostly M_2) inhibit ACh release.

3) *EEG Activation*. There is considerable evidence that in animals nicotine causes EEG activation (Domino, 1967). The EEG activating effects of small doses of nicotine occur in intact as well as brainstem transected animals. These effects of nicotine are directly on brainstem neuronal circuits. However, stimulation of peripheral afferents and release of catecholamines and possibly other neurotransmitters and modulators (serotonin, histamine) enhances the direct central effects of nicotine.

4) *Behavioral Arousal*. The EEG activating effects of nicotine result in behavioral arousal (Domino et al., 1967). In tobacco smokers, depending on circumstances, nicotine can have either sedative or stimulant effects (Kumar and Lader, 1981). Aceto and Martin (1982) have reviewed the large variety of nic-

otine effects on behavior including facilitation of memory, the increase in spontaneous activity, its antinociceptive properties, and its suppression of irritability as well as appetite.

5) *REM Sleep*. Nicotine increases the amount of REM sleep, an effect also seen with arginine vasopressin (Domino & Yamamoto, 1965). This observation in cats has not been pursued. It has many important implications regarding the sleep cycle of tobacco smokers and should be studied further.

6) *Cerebral Metabolism*. Inasmuch as both behavioral arousal and REM sleep increase cerebral metabolism, it would be expected that nicotine would also produce important alterations in cerebral metabolism. It would be of special interest to compare the location of ^{3}H-nicotine binding in the brain with its effects on local cerebral glucose utilization. London et al. (1985a) have done such a study using the rat. Nicotine stimulated local cerebral glucose utilization 139 percent over control in the medial habenula and 50 to 100 percent in the superior colliculus and the anteroventral thalamic and interpeduncular nuclei. Other areas of the brain showed moderate to no significant changes. These effects of nicotine were blocked by mecamylamine. Furthermore, they correlated well with the distribution of ^{3}H-nicotine in the brain except in layer IV of the neocortex which showed nicotine binding, but no change in local cerebral glucose utilization.

7) *Skeletal Muscle*. Nicotine and tobacco smoking dramatically reduce phasic stretch reflexes such as the patellar reflex in human volunteers (Domino & Von Baumgarten, 1969). Both central and peripheral mechanisms are involved. Not all skeletal muscles are relaxed by nicotine. Skeletal muscles involved in the orienting reflex (trapezius) show enhanced tension (Fagerström & Götestam, 1977).

8) *Cardiovascular, Respiratory, and Gastrointestinal Systems*. Nicotine and tobacco smoking have profound effects on these systems. These effects have been described in detail elsewhere (*see* textbook, Gilman et al., 1985).

9) *Conditioned-Avoidance and Self-Stimulation Behavior*. Conditioned-avoidance behavior is selectively depressed by nicotine (Domino, 1965). Its effects on self-stimulation behavior are complex (Olds and Domino, 1969) but usually depressant on single dose administration.

10) *Stimulus Discrimination*. The stimulus discrimination properties of nicotine have been extensively studied by Rosecrans and Chance (1977). Romano et al. (1981) compared a number of nicotinic agonists as cues in rats using a T-maze paradigm. (+) Nicotine which is the enantiomer of natural or (−) nicotine was much less potent, and both position isomers (2- and 4-nicotine) were inactive. Anabasine provided a nicotine cue, but subcutaneous cytisine did not. However, intraventricular (i.v.t.) cytisine was a partially effective cue. The cue effects were blocked by low doses of mecamylamine and pempidine and high doses of C_6. Their findings suggest that the cue receptor is in the brain, and is pharmacologically similar to the nicotinic cholinergic ganglionic receptor.

11) *Self-Administration*. Nicotine self-administration readily occurs in both animals and man (*see* Henningfield, 1984) which probably accounts for the habit of tobacco smoking. Most of the earlier reports on intravenous nicotine self-administration indicate that the reinforcing properties of nicotine are generally weak compared to other classes of drugs of abuse such as stimulants, opiates, and sedative-hypnotics when continuous reinforcement or fixed ratio schedules are used. However, recent studies using interval and second order schedules of nicotine produce persistent behavior at high rates (Dougherty et al., 1981; Goldberg et al., 1981).

12) *Endocrine System*. Nicotine produces profound neuroendocrine changes, including elevated plasma catecholamines, glucose, glucagon, cortisol, insulin, and vasopressin (*see* Domino, 1979, and textbook, Gilman et al., 1985).

13) *Tachyphylaxis, Tolerance, Sensitization*. Nicotine produces tachyphylaxis, tolerance, and sensitization which vary in different organs and systems. Initially in animals nicotine depresses locomotor activity, but when given chronically nicotine markedly stimulates locomotor activity. In chronic nicotine treated rats Clarke and Kumar (1983) have shown that (−) nicotine is 10 times as potent as (+) nicotine in stimulating motor activity. Mecamylamine prevented the locomotor stimulant effects of nicotine, while chlorisonda-

mine only partially reduced it, suggesting that nicotine was acting centrally. When given i.v.t., chlorisondamine blocked the stimulant actions of nicotine for at least 3 weeks.

14) *Pharmacogenetic and Personality Factors.* Considerable individual variability occurs in response to nicotine, suggesting important pharmacogenetic and personality factors.

15) *Up-Regulation of Cholinergic Receptors.* Contrary to expectations, chronic nicotine tends to cause up-regulation of cholinergic receptors. Schwartz and Kellar (1983) showed, as expected from the findings of Russell et al. (1981), that 10 days after the daily administration of DFP, ^{3}H-ACh binding is down-regulated in the rat brain. In contrast, after 10 days of nicotine administration twice daily, ^{3}H-ACh binding is increased. In both cases the affinity was not altered, but only the B_{max}. Subsequently, Schwartz and Kellar (1985) extended their findings to a high affinity ^{3}H-ACh binding site. Furthermore, the nicotinic antagonists mecamylamine and dihydro-β-erythroidine did not alter ^{3}H-ACh binding after 10 to 14 days of treatment alone or with concurrent nicotine. They suggest that ^{3}H-ACh binding sites on nicotinic receptors are subject to up- as well as down-regulation, probably through protracted desensitization of the recognition site. However, if continuous desensitization were the primary mechanism, one would not expect behaviors like locomotor stimulation to be enhanced after chronic nicotine. Marks et al. (1983) have pursued this issue using chronic nicotine infusions on tolerance development and number of nicotine receptors using mice. They conclude that chronic nicotine results in tolerance to a variety of physiological endpoints such as rotarod performance, heart rate, and body temperature. At the same time, there is an increase in brain nicotine receptors. Ksir et al. (1985) also have shown, using rats, that daily administration of nicotine enhances its locomotor stimulant effects and increases ^{3}H-ACh binding to brain nicotinic receptors. They suggest that the data imply the two phenomena are functionally linked. Marks and Collins (1985) also studied tolerance, cross-tolerance, and the number of M and N receptors after chronic nicotine or oxotremorine given to mice. Chronic oxotremorine caused down-regulation of M-receptors, while chronic nicotine caused up-regulation of N-receptors. Some cross-tolerance occurred to the effects of nicotine in the oxotremorine treated mice which did not appear related to changes in nicotinic receptors. Nicotine treated mice were tolerant to six different physiologic measures as were the oxotremorine treated mice.

Conclusions

Nicotine produces a most complex series of effects at multiple sites throughout the body. It is indeed a most remarkable psychoactive substance. Nicotine alters the complex of balance of functions of muscarinic and nicotinic pre- and postsynaptic cholinergic receptors, as well as acting through noncholinergic mechanisms.

Nicotine as a Psychoactive Drug: Appetite Regulation

Neil E. Grunberg, Ph.D.[1]

Introduction

Cigarette smokers weigh less than comparably aged nonsmokers, and habitual smokers who quit smoking generally gain weight (Grunberg, 1982; 1985; Wack & Rodin, 1982). Three major explanations have been proposed to account for these phenomena: (1) changes in consumption of all foods; (2) changes in energy utilization; (3) changes in consumption of particular foods. More specifically, the first postulate holds that smokers eat less than do nonsmokers and that smoking cessation is accompanied by increased food consumption. These changes in eating behavior may result from changes in hunger or a need to substitute food for cigarettes. The second explanation is that some component of tobacco (probably nicotine) increases metabolism and thereby results in decreased body weight without changes in caloric intake. Abstinence from smoking may result in a relative decrease in metabolism so that body weight increases without changes in food consumption. The third hypothesis is that cigarette smoking is accompanied by decreased consumption of sweet-tasting high caloric foods and that consumption of these particular foods increases when smokers kick their habit. Changes in caloric intake from these foods is thought to cause changes in body weight. Although these ideas are all quite reasonable, until recently there was little empirical reason to believe any one of them. A series of human and animal studies was begun in 1979 to investigate the relationship between smoking and body weight and between nicotine and body weight. Some of these studies are reviewed in this paper and the results of these studies are discussed in terms of clinical implications and future research directions.

General or Specific Food Consumption?

In a human laboratory study smokers and nonsmokers (18–36 years old; males and females) participated in a taste judgment study (Grunberg, 1982). Smokers (individuals who smoked at least 15 cigarettes per day for at least 2 years) abstained from smoking during the morning of the experiment. The study was run around lunchtime. The smokers were divided into two equal groups: smokers allowed to smoke immediately before tasting foods and smokers not allowed to smoke before the taste test. Subjects were presented with nine different foods (three sweet, three salty, and three bland) that were provided as bite-sized pieces in separate bowls. Subjects were instructed to taste each food and to rate each food on a series of taste-judgment scales. Water was provided for mouth-rinsing between tastes. Subjects were told that when they finished tasting and rating the foods, they could eat whatever they wanted, but that they should first be sure that all foods were carefully rated. Subjects were left with the foods for 20 minutes to allow time for the taste ratings and still plenty of time to nibble. All bowls of food were weighed before and after the study. After tasting the foods, subjects picked three foods to taste again for another part of the study. These procedures provided data on taste preferences based on actual food consumption and self-reports.

The results of this study are presented in Figure 1. Smokers allowed to smoke ate significantly less sweets than did nonsmokers and less sweets than did smokers not allowed to smoke. Consumption of the salty and bland foods were similar in all three groups of sub-

jects. Based on self-reports, smokers not allowed to smoke expressed the greatest preference for sweets and smokers smoking expressed the least preference for sweets.

An animal study was designed to complement the human laboratory study (Grunberg, 1982). In the animal study nicotine administration was manipulated in order to determine whether this pharmacologic agent, which is generally accepted to be the dependence-producing component of tobacco, also alters body weight. Male Sprague-Dawley rats were the subjects. Animals received subcutaneous administration via Alzet osmotic minipumps of either 0, 2.5, 5.0, or 10.0 mg nicotine per kg body weight per day. Subjects were individually housed and were provided with a standard laboratory chow, three sugar solutions (35%, 25%, and 10% w/v d-glucose), and water. Body weight, food, water, and sugar solution consumption were measured daily for 2-week periods before, during, and after nicotine administration. The within and between subjects design of this study allowed for careful evaluation of the effects of nicotine on general food consumption, specific taste preferences for sweet versus nonsweet foods, and body weight.

Figure 2 presents the mean body weights for each group of animals for each phase of the study. Individual data points represent a composite of the data from each experimental group averaged over many days. Comparing the changes in body weight from before to during drug administration, animals receiving nicotine gained significantly less weight than did control animals. After cessation of nicotine, animals in the experimental groups gained more weight than did animals receiving saline.

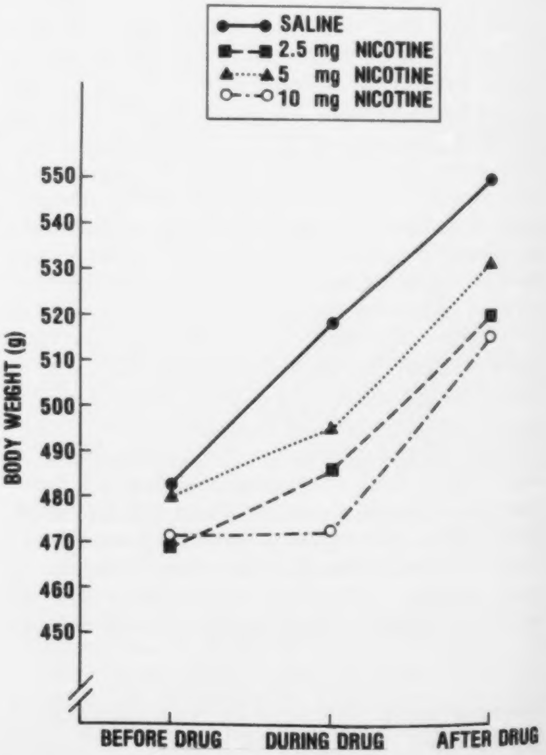

FIGURE 2. Average body weights before, during, and after drug administration. (Reprinted with permission from *Addictive Behaviors*, Vol. 7, Grunberg, N.E., The effects of nicotine and cigarette smoking on food consumption and taste preferences, 1982, Pergamon Press, Ltd.)

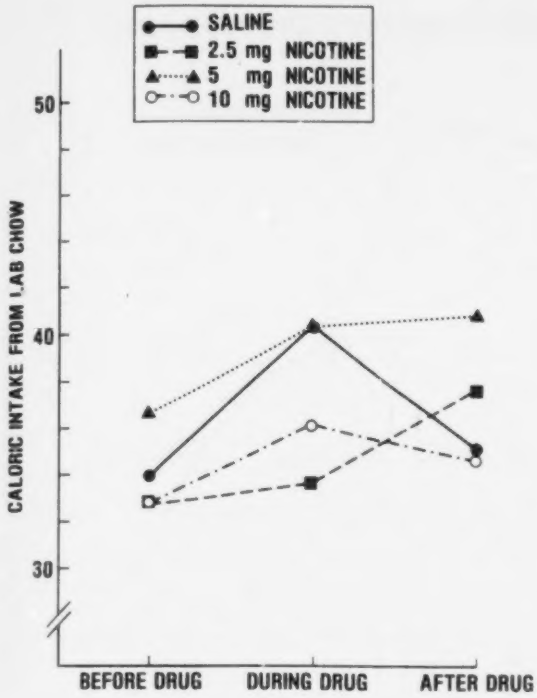

FIGURE 3. Average caloric intake from lab chow before, during, and after drug administration. (Reprinted with permission from *Addictive Behaviors*, Vol. 7, Grunberg, N.E., The effects of nicotine and cigarette smoking on food consumption and taste preferences, 1982, Pergamon Press, Ltd.)

Figure 3 indicates that there were no consistent effects of nicotine administration or cessation of nicotine on consumption of the bland laboratory chow. In marked contrast, Figure 4 indicates that animals receiving nicotine significantly decreased consumption of the sugar solutions during drug administration. After cessation of nicotine, animals significantly increased their consumption of sugar solutions. These changes in sweet food consumption resulted in significant changes in caloric intake that could account for the changes in body weight.

Are These Laboratory Findings Generalizable?

An archival epidemiological study was conducted to determine whether the laboratory results regarding nicotine and sweet foods were a robust phenomenon that also appeared in the entire United States population (Grunberg & Morse, 1984). United States per capita consumption of cigarettes was compared to U.S. per capita consumption of all major food groups during a 14-year period. Figure 5 presents the data for cigarettes and sugar. Consistent with the laboratory studies, there was a significant inverse relationship between cigarette and sugar consumption.

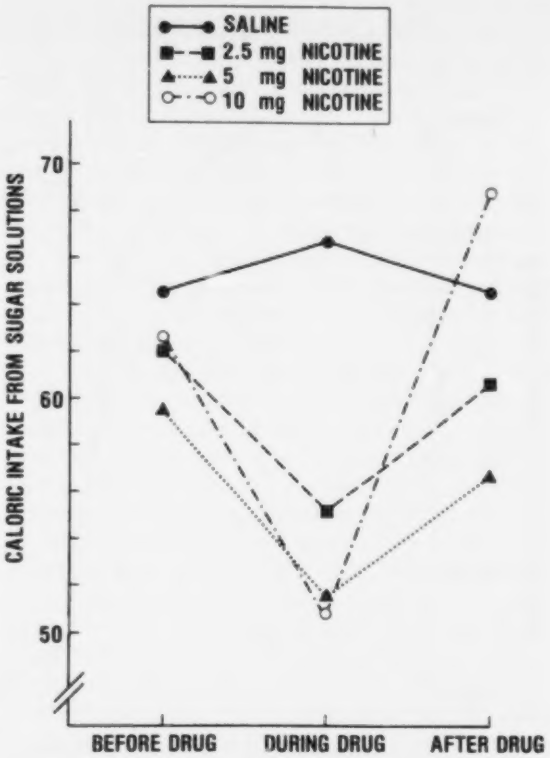

FIGURE 4. Average caloric intake from sugar solutions. (Reprinted with permission from *Addictive Behaviors*, Vol. 7, Grunberg, N.E., The effects of nicotine and cigarette smoking on food consumption and taste preferences, 1982, Pergamon Press, Ltd.)

What Happens if Only Bland Foods Are Available?

The preceding data are consistent with the proposition that changes in specific food consumption (sweets) accompany smoking and abstinence from smoking and that these changes may account for changes in body weight. There were no changes in consumption of nonsweet foods in the animal and

human studies. These results suggest that if only bland food is available, there will be no changes in caloric intake during or after nicotine administration and there will be no changes in body weight. Animal studies were performed to examine directly the effects of nicotine on body weight and bland food consumption (Grunberg, Bowen, & Morse, 1984).

The animal paradigm described previously was followed except that only bland laboratory chow and water were available and the nicotine dosages were slightly different (0, 4, 8, and 12 mg/kg/day). Figure 6 presents the mean body weight values for each group of animals for 6-day periods before, during, and after drug administration. There was an inverse dose-effect relationship between nicotine administration and body weight. These effects of nicotine on body weight were slightly attenuated compared to the previous study when sugar solutions were available. After cessation of nicotine administration, all groups of animals gained similar amounts of weight as did control animals. That is, in contrast to the previous study, animals that had received nicotine did *not* gain excessive amounts of weight. Analyses of food and water consumption revealed that there were no differences between experimental groups during any phase of the study and for either of these variables. To summarize, when only bland food was available, there were no effects of nicotine or cessation of nicotine on eating behavior; the effects of nicotine administration on body weight were slightly attenuated; and there was no excessive gain in body weight after cessation of nicotine. To

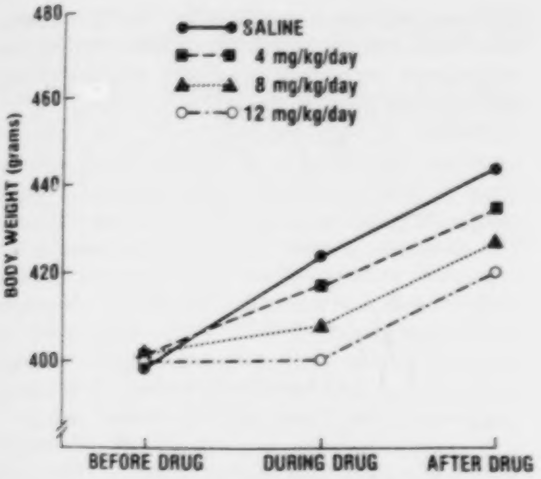

FIGURE 6. Average body weights before, during, and after drug administration when only nonsweet foods were available. double check these findings, a similar study was run with a longer nicotine administration period. All results were identical. Therefore, it seems that nicotine only affects consumption of sweet foods and this effect is particularly important in post-nicotine excessive body weight gains.

Sweet Taste vs. Caloric Content

In the animal and human studies of sweet food consumption, the foods that had sweet taste also were high in caloric content and carbohydrate content. Therefore, it is impossible to know which of these factors is responsible for nicotine's effects in changing specific food consumption. A series of animal studies was conducted to separate these factors (Grunberg, Bowen, Maycock, & Nespor, 1985). In one study, rats had continuous access to water and two foods: a sweet-tasting (saccharin flavored), low-calorie food and a nonsweet, low-calorie food. The foods were identical in nutrient constituents. Three groups of animals (0, 6, 12 mg nicotine/kg/day) were examined for weeks before, during, and after drug administration. There was an inverse dose-effect relationship between nicotine and body weight during drug administration and a positive relationship between nicotine and body weight gain after cessation of nicotine. Animals receiving nicotine decreased consumption of the sweet food compared to controls during the drug administration period. After the drug administration phase, animals that had received nicotine increased sweet-food consumption compared to controls. Consumption of the nonsweet foods showed opposite effects as the animals clearly switched their preferences during and after drug administration.

In a related animal study the two foods were both nonsweet but one had high-caloric value (by increasing carbohydrate content) and the other had low-caloric value. Again, there was an inverse relationship between nicotine and body weight during drug administration and a positive relationship between nicotine and body weight gain after cessation of nicotine. The effects of nicotine on consumption of the high-caloric carbohydrate food were similar to, but substantially weaker than, the effects on sweet-food consumption. Therefore, both sweet taste and caloric content contributed to the effects of nicotine on specific food consumption but sweet taste was particularly important.

Males vs. Females

Women seem to be more concerned than men about weight gains after cessation of smoking. This concern may reflect society-induced gender differences in attention to body weight and physical appearance. Alternatively, cigarette smoking and nicotine may have different effects on women and men. All of the animal studies cited above used male subjects. Therefore, female rats were used as subjects in a study designed to be comparable to the studies of nicotine, body weight, and bland food consumption (Grunberg, Bowen, & Winders, 1985). Animals were used as subjects for all of the reasons described earlier. In addition, it was assumed that animals would not be self-conscious about their body weight and eating behavior. Therefore, the effects of nicotine could be evaluated without concern for such psychological variables as restraint in eating. The effects of every dose of nicotine (adjusted for initial body weight) were greater on the body weight, food consumption, and water consumption of the females compared to similar studies with males. In fact, the highest dosage of nicotine decreased consumption of the bland food. After cessation of nicotine, eating behavior increased. These effects were markedly different from previous studies of male animals. Also, there was an inverse relationship between nicotine and water consumption. In male animal studies, water consumption was never affected by nicotine. These sex differences are currently under additional examination and, so far, continue to show up. It seems that women's concerns about body weight gains after abstaining from cigarettes may reflect biobehavioral differences in the effects of nicotine.

Possible Implications

The results of these studies have both clinical and basic science implications. Taken together, these studies suggest that smokers who quit smoking should especially avoid sweet-tasting, high caloric foods; and might try using noncaloric sweeteners on foods. Women who quit smoking also should monitor consumption of nonsweet foods (but addition of noncaloric sweeteners may help control excessive food consumption). These suggestions are, of course, extrapolations from the data discussed and therefore require careful clinical assessment before any of these approaches can be touted as effective.

On a theoretical level, it is worth considering why preferences for sweet tastes and carbohydrates are altered by nicotine. Perhaps nicotine alters glucose availability in the body and hedonic preference for sweet tastes is altered in response to this biochemical mechanism (Grunberg, 1985; Grunberg et al., 1985). This possibility is currently under investigation. The altered preference for foods based on carbohydrate content is another issue that merits further investigation. Possibly, smokers who give up cigarettes experience the marked and almost unbearable unpleasantness of abstinence and eat carbohydrates to modulate and improve mood. In effect, the specific food consumption might be considered as self-administration of a psychopharmacologic agent to regulate affect. This conjecture is speculative, but it is consistent with recent research evidence that carbohydrate consumption alters mood (Spring, Lieberman, Swope, & Garfield, 1984).

Finally, it may be interesting to consider whether the effects of nicotine on specific food consumption reflects general mechanisms common to other drugs of dependence. For example, sweet-tasting carbohydrates are reported to help offset the unpleasantness of withdrawal from alcohol (Griffiths, Bigelow, & Henningfield, 1980). Also, anecdotal reports indicate that narcotics addicts crave sugar when they kick their habits. It has been suggested that these effects reflect underlying commonalities among drugs of dependence (Grunberg & Baum, 1985). This possibility also deserves careful empirical attention.

Conclusion

Classic studies using nicotine have provided critical knowledge about general physiological processes involving nicotinic vs. muscarinic receptors. More recently, the role of nicotine as the pharmacologic agent of dependence to tobacco has emerged as a central topic in smoking research and treatment. Now, it is clear that nicotine alters body weight and that studies of nicotine's effects on specific food consumption may reveal useful clinical knowledge and may provide theoretical insights regarding the biological bases for specific food cravings.

Nicotine as a Psychoactive Drug—Panel Summary

Murray E. Jarvik[1]

The four members of this panel have emphasized some of the more important reinforcing properties of nicotine, the major pharmacological agent in tobacco. People smoke for at least five reasons: to increase arousal, improve attention, reduce anxiety, control aggression, and decrease appetite. Another important impetus to smoking is withdrawal relief. On the other hand, people desist from smoking for very different and primarily nonpharmacological reasons. A combination of social pressure and fear of deleterious health consequences has profoundly decreased the incidence of smoking in the United States and in certain other parts of the world. Relapse after smoking cessation is a particularly interesting psychological phenomenon illustrating the conflict between the positive reinforcing actions of nicotine and the social and intellectual forces tending to diminish smoking.

Many studies have unequivocally shown that stress increases the rate of smoking cigarettes. Pomerleau, Domino, and Jarvik are particularly interested in possible mechanisms underlying this effect. There are probably many components to this phenomenon. First, the nonspecific activating action of stress may have a tendency to increase all types of habitual behavior, and particularly drug taking, whether of sedative or stimulant drugs. Nevertheless, most smokers do report an anxiety-reducing effect of smoking in everyday life. It has been much more difficult to demonstrate anxiety reduction from experimentally induced stress in the laboratory by either nicotine or cigarette smoking. Nonetheless, in some studies induction of both mental and physical distress has been shown to be relieved by nicotine administration. Reduction of aggression by nicotine may be a related phenomenon. The pathways involving the induction of dysphoria are diverse, but there is presumably some final common pathway which is acted upon by nicotine. Physiological explanations of the antianxiety effects of nicotine are still forthcoming, but it is well known that nicotine induces a complex cascade of neural hormones, including peptides such as endogenous opioids, components of the hypothalamic pituitary axis, and a variety of biogenic amines, among others. Analysis of the relative importance of each of these components has begun in various laboratories utilizing agonists and antagonists to these compounds.

The peculiar stimulant properties of nicotine have been used by millions of smokers to improve the quality of intellectual work. Evidence from a variety of laboratories indicates that performance in a variety of tasks of concentration, vigilance, and perception are indeed improved by appropriate doses of nicotine both in smokers and (more importantly) nonsmokers. The electrophysiological changes in the brain and other parts of the nervous system which might be responsible for such effects have been reviewed by Dr. Domino to illustrate how this drug might facilitate intellectual performance such as perception, learning, and memory.

The reduction of anxiety and irritability may also contribute to enhanced performance and euphoria. The work of Dr. Don Cherek on the ability of nicotine to reduce aggression is particularly pertinent in this respect and may involve some of the same mechanisms implicated in anxiety reduction.

The homeostatic mechanisms of feeding have been perhaps more intensively studied by psychophysiologists than any other form of reinforcement. The analogies between eating and smoking are so strong that it is hard to ignore the similarities and to assume that somewhere there must be either intersecting or final common pathways involved. Both smoking and eating are forms of oral gratification, a point early recognized by psychodynamic theorists. Of more empirical importance is the fact that smoking unequivocally results in weight reduction, and as Dr. Grunberg has pointed out, there are probably two factors involved: a metabolic enhancement by nicotine and a selective depression of desire for sweet, caloric foods. Again, the mechanisms and particularly the involvement of specific anatomical sites have not been clarified. A related important paradoxical finding by Edythe London and collaborators at the National Institute on Drug Abuse has indicated that the hypothalamus is virtually devoid of nicotinic receptors, so that the interaction between feeding and smoking must somehow be indirectly mediated. Another aspect of eating and smoking which Jarvik and collaborators have been particularly concerned with is the highly reinforcing nature of the postprandial cigarette. This is a very robust phenomenon which almost all smokers experience, but the mechanism of which has not yet been revealed.

In summary, we would have to conclude that although the evidence linking smoking to disease is incontrovertible, nonetheless nicotine has some positive virtues which are worth pursuing for their own sake. If nicotine could be administered free of the harmful effects of tobacco, many of the deleterious effects could be eliminated. In fact, nicotine has been given orally, by inhalation, nasally, sublingually, intravenously, and transdermally. While this alkaloid does have intrinsically harmful cardiovascular effects, further research might reveal ways of dealing with these so that this drug might still have promise as a pharmacologically useful therapeutic agent.

Electrophysiological Evidence Implicating Frontal Lobe Dysfunction in Schizophrenia

John M. Morihisa, M.D.[1]

The importance of the frontal lobes in the pathogenesis of schizophrenia has its roots in the neuroanatomic foundations of modern psychiatry (Morihisa & Weinberger, 1986). Indeed, Alzheimer (1913) felt that pathology in layers II and III of the frontal lobes had a significant role in the etiology of schizophrenia (dementia praecox). In addition, phenomenological studies of this disorder have highlighted a number of clinical manifestations that yield a constellation of symptoms that is strikingly similar to what we have come to associate with neurologic cases of frontal lobe disease. This symptom complex would include: poor insight, social withdrawal, decreased behavioral spontaneity, ineffectiveness, inattentiveness, and lack of interest in personal hygiene (Morihisa & Weinberger, 1986). This is not to say that the entire spectrum of symptoms that can be associated with schizophrenia is congruent with those demonstrated by neurologic patients with clear frontal lobe disease. Instead, we would suggest that a subgroup of schizophrenic patients often exhibit a subset of symptoms that are quite reminiscent of a frontal-lobe syndrome. In schizophrenia, this grouping of symptoms has had sufficient heuristic value to form the basis for several clinical subtyping strategies in schizophrenia. The clinical categorizations of "negative symptom" type or "defect symptom state" schizophrenia would appear closest in content to those that might support an involvement of frontal lobe pathology. Encouraged by these theoretical suspicions and circumstantial clinical evidence, interest has focused on techniques that might provide direct measurement of frontal lobe abnormalities in schizophrenia.

The earliest findings were derived from pneumoencephalography which suggested structural pathology of the central nervous system in schizophrenia. However, it would require an evolutionary step in radiology to allow more specific structural investigations in the form of computed tomography. During this period, a parallel avenue of investigation was developing. This was the introduction of topographic electrophysiologic approaches to examine brain function. Pioneering work was led by Walter and Shipton (1951), Petsche (1954), and Remond

---

(1955) and extended by Estrin and Uzgalis (1969), Lehman (1971), Bickford and colleagues (1972), and Gotman & Gloor (1975). In 1979, Duffy et al. introduced a computerized topographic mapping system, brain electrical activity mapping, which built upon several decades of work in the field.

Our study employed a Duffy system that utilized a standard convention for the placement of electroencephalograph (EEG) electrodes, the International 10–20 System. All electrodes were referenced to linked ears and additional electrodes were attached to monitor eye movements. The data from these leads were amplified through Grass 7P511 amplifiers and recorded on a Honeywell 5600E 28 channel FM analog tape recorder for off-line processing by a DEC PDP 11–60 computer. Prior to analysis all data were visually inspected and segments containing eye blinks, eye movements, muscle potentials, movement artifacts, or 60 Hz interference were eliminated. A spectral analysis was performed using the Fast Fourier Transform algorithm (Cooley & Tukey, 1976). Topographic maps of this spectral analysis were used to present condensed and summarized EEG data. These maps can also demonstrate epochs of simple visual (flash) or auditory (click) evoked potentials or display statistical information in topographic format (Duffy et al., 1979, 1981).

In 1983 this computerized topographic technique was systematically applied to the study of schizophrenia (Morihisa et al., 1983). This study compared drug-free schizophrenic patients and medicated schizophrenic patients to normal controls. Schizophrenic patients fulfilled *DSM–III* and Research Diagnostic Criteria and drug-free patients were unmedicated for at least 4 weeks and medicated patients were on a standardized dose of haloperidol (0.4 mg/kg) for at least 4 weeks. The patients were not significantly different from the controls for age, gender, or handedness. The major finding of this study was that schizophrenic patients demonstrated more delta activity over the entire cortical surface than did controls. Furthermore, the drug-free patients demonstrated greater delta activity than the medicated patients. Thus, the greater delta activity in schizophrenic patients does not appear to be an acute effect of medication. The increased delta activity in schizophrenia was seen over the entire cortical surface. This finding contributes further evidence of brain abnormalities in this disorder. In order to further refine our pathophysiological focus we must complement this approach with techniques which measure brain metabolism and structure (Morihisa, 1985*b*). The importance of using multiple complementary brain imaging techniques is emphasized by the vulnerability of EEG studies to artifactual contamination and the fact that EEG studies are generally limited to recordings from the cortical surface (Morihisa, in press).

Supporting Evidence From Positron Emission Tomography (PET)

Recent studies using positron emission tomography support the involvement of frontal lobe abnormalities in schizophrenia. Buchsbaum et al. (1982, 1984) reported abnormalities of the anteroposterior gradient of glucose metabolism in schizophrenic patients compared to controls. Although these findings have been also reported in affective disorders and other groups have failed to replicate this result, one of the most recent investigations using positron emission tomography (Wolkin et al., 1985) has taken the argument a step further by demonstrating a finding of specifically decreased absolute glucose metabolism in the frontal lobes of schizophrenic patients.

Supporting Structural Evidence

Recent structural evidence has been reported using computerized tomography (Weinberger, 1984; Shelton et al., 1985) that found subtle atrophy of the frontal cortex in schizophrenic patients. Andreasen and colleagues (1986) have introduced a new brain imaging strategy in the investigation of frontal lobe pathology in schizophrenia, magnetic resonance imaging (MRI). Andreasen and her co-workers report (1986) that schizophrenic patients had significantly smaller frontal lobes than normal controls.

Supporting Evidence From Regional Cerebral Blood Flow (rCBF)

This evidence of frontal lobe dysfunction is consistent with the work of Ingvar and colleagues (1974) who reported a relative decrease in frontal cerebral blood flow in schizophrenic patients compared to alcoholic controls. Although there were a number of limitations to Ingvar's original studies (Berman et al., 1984), recent work by Weinberger and colleagues using xenon-133 regional cerebral blood flow has refocused attention on frontal lobe dysfunction in schizophrenia.

Weinberger and colleagues (Berman et al., 1984; Weinberger et al., 1986; Berman et al., 1986) used a cognitive activation test, the Wisconsin Card Sort, to place a specific demand on the dorsolateral prefrontal cortex. Neuroscience findings have suggested that this activation task will selectively test the functional integrity of the dorsolateral prefrontal cortex (Weinberger et al., 1986). Weinberger found that normal subjects demonstrated the expected increase in blood flow in the prefrontal region but schizophrenic patients failed to do so. Thus, this application of rCBF adds further evidence implicating frontal lobe pathology in schizophrenia and suggests that we refine our focus to the dorsolateral prefrontal cortex.

We next hope to use the Wisconsin Card Sort paradigm as a cognitive activation task in an investigation of schizophrenia using computerized topographic mapping (Morihisa, in press). This would represent an important next step in the computerized topographic EEG investigation of frontal lobe dysfunction in schizophrenia. First, this strategy uses a cognitive activation task as opposed to measuring the difficult-to-control resting alert cognitive state. Second, this particular cognitive activation task selectively places a demand upon a specific component of the frontal lobes and thereby may allow greater resolution of pathologic localization (Morihisa & Weinberger, 1986).

Combining EEG Topographic Approaches With Other Brain Imaging Techniques

The utility of matching complementary brain imaging techniques reflects the fact that each of these approaches has specific limitations and measures quite different parameters of brain function. Thus, by combining the strengths and information of different imaging techniques we can build the strongest case for hypothesizing specific patterns of pathophysiology (Morihisa, 1984).

Our most recent computerized topographic study (Morihisa & McAnulty, 1985) of EEG and evoked potentials employed computed tomography to provide a structural basis for the electrophysiological comparison of two groups of schizophrenic patients. In this pilot study we explored the relationship of anatomic pathology and electrophysiological differences between a group of schizophrenic patients with frontal atrophy versus a group of schizophrenic patients without frontal atrophy. This preliminary investigation delineated four regional differences between these two groups, all of which overlay frontal cortical regions (Figure 1). These findings suggest that, in schizophrenia, differences in electrophysiological function may be associated with definable gross morphologic abnormalities of the brain (Morihisa & McAnulty, 1985).

Conclusion

Thus, a compelling body of evidence has been reported implicating frontal lobe dysfunction as a process that may be important to our understanding of schizophrenia. However, despite some convergence in findings, caution must be exercised in the interpretation of this seemingly meaningful constellation of findings from clinical observation and functional and structural brain imaging techniques. First, a number of contradictory results have been reported using rCBF, PET scan, and computerized topographic EEG approaches. Second, these findings suggestive of frontal pathology have not been found in all patients with schizophrenia and, perhaps even more confounding, PET studies have reported similar abnormalities in patients with affective disorders. Finally, schizophrenia encompasses a wide range of clinical manifestations which suggest a heterogeneity of pathology and perhaps etiology.

Although computerized topographic electrophysiological studies are consistent with

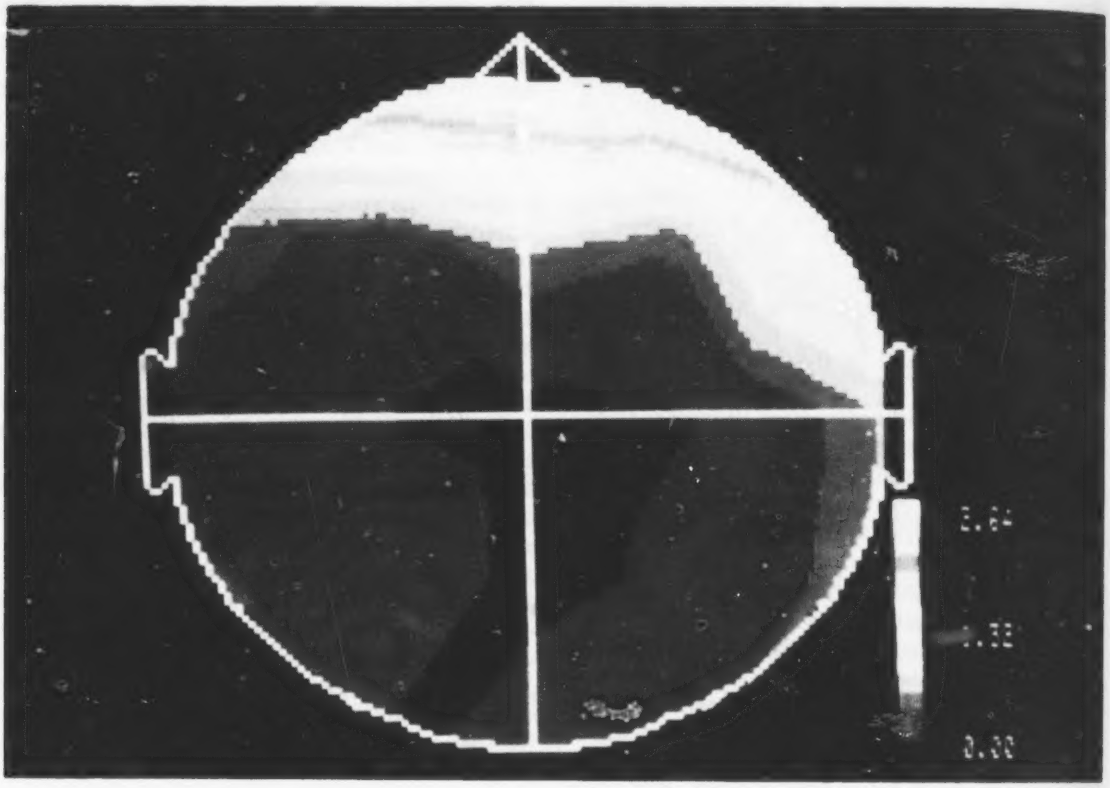

FIGURE 1. This is a brain electrical activity map that compares electrophysiological data (visual evoked potential) for two groups of schizophrenic patients: schizophrenic patients who demonstrate frontal atrophy on computed tomography scan versus schizophrenic patients who show no evidence of frontal atrophy. Greatest difference is presented in white and overlies the frontal lobes. This is one of four maps that were elucidated in this study, all of which involved regions overlying the frontal lobes.

the hypothesis of frontal lobe pathology in schizophrenia, the inherent limitations of these approaches and the lack of a unitary body of findings emphasize the urgency for further studies, especially those employing complementary brain imaging approaches in concert to enlarge and enhance our scientific window of investigation (Morihisa, in press).

Supersensitivity Psychosis and Tardive Dyskinesia: A Survey in Schizophrenic Outpatients

Guy Chouinard, M.D., M.Sc. (Pharmacol), F.R.C.P.(C),[1,2,3] Lawrence Annable, B.Sc., Dip. Stat.,[1,2] and Andree Ross-Chouinard, M.D. (Neurology), F.R.C.P.(C)[1,2]

Long-term administration of neuroleptics is currently the most efficacious treatment for chronic schizophrenia. However, this type of treatment is not without serious risk, particularly for the central nervous system. Abnormal movements of choreoathetoid type called tardive dyskinesia have been reported to occur in 20 to 40 percent of patients receiving neuroleptics (American Psychiatric Association Task Force Report, 1979) and can be potentially irreversible, especially after the age of 40. We reported another long-term side effect of neuroleptic treatment which we called supersensitivity psychosis (Chouinard et al., 1978; Chouinard & Jones, 1980). Receptor changes in the dopaminergic pathways of the mesolimbic (Davis & Rosenberg, 1979) or other nonstriatal dopaminergic regions of the brain could explain the disorder in the same way that changes in the neostriatum are thought to be responsible for tardive dyskinesia.

There are difficulties associated with the diagnosis of supersensitivity psychosis (Chouinard & Jones, 1982). The symptoms of the latter are nearly the same as the disease process itself; the distinctions being that only positive symptoms of schizophrenia are exhibited, that the symptoms fluctuate according to the masking effect of increased neuroleptic dose or unmasking effect of decreased dose, and that relapses occur more rapidly than would be expected from the normal course of the illness. In this respect, perhaps it is worth mentioning that the symptoms of tardive dyskinesia have also been mistaken for mannerisms of schizophrenia, hyperkinetic parkinsonian side effects (akathisia or tremors), and senile choreic movements.

As with tardive dyskinesia, clinical symptoms of supersensitivity psychosis are masked by neuroleptics. Since all the neuroleptics presently available have prolonged half-lives,

recognition of the disorder is difficult. One would predict that metaclopramide, a short-acting dopamine (DA) receptor blocking agent, when given in doses effective in treating schizophrenia, would give clear evidence of supersensitivity relapse upon abrupt withdrawal. Cases of supersensitivity psychosis have been reported following withdrawal of clozapine (Ekholm et al., 1984; Perenyi et al., 1985), a drug with a short half-life and a greater affinity for mesolimbic than striatal DA receptors. Other cases have been reported following withdrawal of neuroleptics in manic-depressive illness (Witschy et al., 1984; Duff et al., in preparation), and reserpine (Kent & Wilber, 1982).

The disorder may be less readily apparent in inpatient populations since, like tardive dyskinesia, supersensitivity psychosis is identified most readily in patients under stress. Tardive dyskinetic symptoms are exacerbated during periods of increased concentration or anxiety. Similarly, the most potent stressors for supersensitivity psychosis are the normal activities of the patient's life which are difficult to recreate in a hospital setting.

Given the difficulties in diagnosing supersensitivity psychosis, we carried out a survey of the disorder in an outpatient population for which conditions of treatment optimized the possibility of observing its presence. At the same time, we carried out a 5-year follow-up study of tardive dyskinesia (Chouinard et al., 1979; Chouinard et al., in press).

Method

For the purposes of this study, the clinical presentation of supersensitivity psychosis was defined as follows: sudden relapse upon neuroleptic dosage decrease or discontinuation with rapid improvement upon re-establishment of neuroleptic treatment, and evidence of CNS tolerance to antipsychotic effect as manifested through a need for a gradual increase in neuroleptic dosage to maintain constant therapeutic effect. Using these criteria, we carried out a cross-sectional survey of supersensitivity psychosis in 224 schizophrenic outpatients chronically maintained on neuroleptic treatment. The patients studied attended an outpatient clinic in which all patients have a diagnosis of schizophrenia according to the Research Diagnostic Criteria (Spitzer et al., 1977). Within the clinic, pharmacotherapy was under strict control and, at the time of the study, the following principles were applied: the minimum therapeutic dose was given; a single neuroleptic was prescribed whenever possible; very few patients received low-potency neuroleptics; drugs were administered in a single daily dose or twice-daily regimen; procyclidine was the only antiparkinsonian drug used; attempts were made to withdraw the antiparkinsonian after 3 months; fluphenazine enanthate, an injectable long-acting drug was given to patients who did not respond to other neuroleptics, those who could not be relied upon to take medication, and those with frequent relapses; polypharmacy was avoided and antidepressant drugs, minor tranquilizers, and hypnotics were not prescribed; medication was reviewed each time the patient came to the clinic.

Patients were rated during their regular visit to the clinic by a psychiatrist (GC) who had been in charge of their treatment for 10 years. The following ratings were carried out: 1) The presence of supersensitivity psychosis, rated on a 3-point rating scale (0 = absent, 1 = doubtful or borderline, 2 = definite). The principal clinical characteristic used for the diagnosis of definite supersensitivity psychosis was a greater relapse rate during continuous neuroleptic treatment than when not continuously treated. Doubtful or borderline cases were classified as such if: a) a patient had developed definite drug tolerance but no definite relapse when medication was decreased; b) patients had showed definite relapse upon decrease or discontinuation of medication, but the relapse occurred shortly after 6 weeks for oral medication or 3 months for depot injectable neuroleptics. 2) Therapeutic response to treatment, rated on a 5-point rating scale (1 = marked improvement and 5 = worse); and 3) Overall severity of illness, rated on a 7-point rating scale (1 = normal and 7 = extremely ill).

The patient's illness was also classified as good or poor prognosis according to criteria similar to those of Robins and Guze (1970) (age of onset and presence of significant residual symptoms being the main criteria). *Independently, patients underwent an extra-*

TABLE 1. Patient Characteristics.

	Men (n = 113)		Women (n = 111)		All Patients (n = 224)	
	Mean	(S.D.)	Mean	(S.D.)	Mean	(S.D.)
Age	41.9	(10.9)	48.4	(11.0)	45.1	(11.4)
Neuroleptic dose (CPZ units)*	706	(885)	454	(552)	587	(750)
Years on neuroleptics	12.7	(6.3)	14.9	(5.8)	13.8	(6.1)

*Neuroleptic medications were converted to mg/day chlorpromazine units according to the equivalency given by Davis (1980). Fluphenazine enanthate was converted to chlorpromazine units on the basis of an equivalency of a dose of 25 mg I.M. every 2 weeks to 150 mg chlorpromazine daily.

pyramidal symptom assessment, using a standardized examination procedure for parkinsonian symptoms and tardive dyskinesia, and were rated on the Extrapyramidal Symptom Rating Scale by a neurologist (AR-C). Blood was drawn for determination of plasma prolactin concentration and was analyzed for neuroleptic activity using a neuroleptic radioreceptor assay (Creese & Snyder, 1977; Lader, 1980; Cohen et al., 1980). Also, various demographic variables were recorded by review of the patient's chart: age, number of years treated with neuroleptics, length of previous psychiatric hospitalizations, current dosage of neuroleptics, number of ECT treatments, number of insulin treatments, presence of brain damage, history of alcoholism, history of antidepressant treatment.

Results

The characteristics of the population studied are shown in Table 1. Women tended to be older but required a lower neuroleptic maintenance dose than men. Table 2 shows the prevalence of tardive dyskinesia, using the Research Diagnostic Criteria of Schooler and Kane (1982) (which require presence of at least "moderate" dyskinetic movements in one or more body areas or at least "mild" dyskinetic movements in two or more body areas), and supersensitivity psychosis. The prevalence of definite cases of supersensitivity psychosis (22%) was about one half that of tardive dyskinesia (45%) and did not vary with sex.

Table 3 compares the age and neuroleptic dosage of patients with and without supersensitivity psychosis and tardive dyskinesia. Patients with supersensitivity psychosis were receiving a larger mean neuroleptic dose than patients without this syndrome ($t = 4.07, p < .001$), but there was no difference with respect to mean age. Patients with tardive dyskinesia, on the other hand, tended to be older than patients without tardive dyskinesia ($t = 4.05, p < .001$), but there was no difference with respect to mean neuroleptic dose.

Patients receiving low-potency neuroleptics tended to have different characteristics from those receiving high potency neuroleptics and were considered as a separate group. Table 4 shows the results for different variables according to the rating given for supersensi-

TABLE 2. Prevalence of Tardive Dyskinesia and Supersensitivity Psychosis.

	Men (n = 113)		Women (n = 111)		All Patients (n = 224)

Supersensitivity Psychosis (2=definite only)	26	23	24	22	50	22
Supersensitivity Psychosis (2=definite; 1=doubtful or borderline)	48	42	49	44	97	43

TABLE 3. Characteristics of Patients With and Without Supersensitivity Psychosis (Definite), and Tardive Dyskinesia (Research Diagnostic Criteria): Mean (S.D.).

	Supersensitivity Psychosis		Tardive Dyskinesia	
	Present (n = 50)	Absent (n = 174)	Present (n = 100)	Absent (n = 124)
Age (yrs)	44 (12)	46 (14)	48 (11)[a]	42 (11)
Neuroleptic dose (mg/day CPZ units)	940 (1002)[b]	472 (614)	625 (854)	526 (632)

[a] Statistically significant ($p < .001$) difference in mean age between patients with and without tardive dyskinesia.
[b] Statistically significant ($p < .01$) difference in mean neuroleptic dose between patients with and without supersensitivity psychosis.

tivity psychosis in patients receiving high-potency neuroleptics only. Patients with a definite diagnosis of supersensitivity psychosis were receiving significantly greater neuroleptic doses ($t = 4.35$, $p < .001$) and had significantly higher prolactin levels (men: $t = 1.68$, $p < .10$; women: $t = 2.38$, $p < .05$) than those without supersensitivity psychosis. There was also a nonsignificant trend for higher neuroleptic radioreceptor assay levels in patients with supersensitivity psychosis than those without the disorder (these were measured in 71 patients only so there was less statistical power to detect differences).

Table 5 shows similar results for patients receiving low-potency neuroleptics. Although the numbers of subjects in this group are small the same trend for increasing neuroleptic dose and radioreceptor assay levels is present in patients with supersensitivity psychosis. In general, patients treated with low-potency drugs tended to be older and have more tardive dyskinesia than the high-potency group.

Table 6 compares patients with supersensitivity psychosis and those without the syndrome with respect to schizophrenic prognosis. There was a tendency ($p < .10$) for supersensitivity psychosis to be more frequent in patients diagnosed as "good prognosis" (atypical, schizophreniform, paranoid subtype) than in those diagnosed as "poor prognosis" (other subtypes).

Discussion

The prevalence of tardive dyskinesia meeting the Schooler and Kane research criteria (1982) in these schizophrenic outpatients was 45 percent, about twice that of diagnosed cases of supersensitivity psychosis, 22 percent. We have elsewhere reported

*Measured in 14 patients only, classified according to supersensitivity psychosis as follows: not present $n = 6$; borderline $n = 3$; definite $n = 3$; not assessed $n = 2$.

(Chouinard et al., in press) that over a 5-year period the annual incidence rate of tardive dyskinesia corrected for remissions in these patients was 2.9 percent, similar to that reported by Kane et al. (1982) from a prospective study of tardive dyskinesia development.

A diagnosis of supersensitivity psychosis was associated with a higher maintenance dose of neuroleptics, high prolactin levels and a "good" schizophrenic prognosis. No relationship was seen, however, between tardive dyskinesia and supersensitivity psychosis. The trend for a higher dose and prolactin level to be seen in patients with supersensitivity psychosis may reflect the development of dopamine supersensitivity in areas of the brain responsible for the appearance of psychotic symptoms. The latter would necessitate increased neuroleptic dosage to maintain clinical improvement. Of course, it could be argued that one of the features used to make the diagnosis was evidence of drug tolerance. However, not all patients were diagnosed based on the presence of this feature and drug tolerance was defined as the need for dosage increases over time after a patient had been stable on a lower dose, and not simply the presence of a large absolute dose of neuroleptic unchanged from the dose needed to control a previous acute relapse of the illness. Thus these indirect measures of increased dopaminergic antagonist activity in patients diagnosed as having supersensitivity psychosis do provide some measure of support for the diagnosis.

TABLE 6. Supersensitivity Psychosis and Schizophrenic Prognosis: Patients Treated With High-Potency Neuroleptics.

	Supersensitivity Psychosis	
Prognosis	Present	Absent
Good prognosis	37	7
Poor prognosis	62	29

$\chi^2 = 3.12$, $p < .10$ (Yates' correction applied).

That patients with good prognosis schizophrenia show a tendency towards greater susceptibility to supersensitivity psychosis could explain the lack of correlation with tardive dyskinesia. Tardive dyskinesia is more often seen in poor prognosis patients (Chouinard et al., 1979) and a different susceptibility based on prognosis could obscure any relationship between these two supersensitivity disorders in an individual patient. In an earlier study carried out with chronically hospitalized inpatients having poor prognosis schizophrenia, we found an association between tardive dyskinesia and supersensitivity psychosis. But, in this outpatient study including both poor and good prognosis patients, such a relationship was not found. It should be mentioned that the great majority of patients included in this study were receiving fluphenazine, given either orally or in the long-acting injectable form (decanoate or enanthate). Further cross-sectional studies involving neuroleptics with more selective D_2 dopamine receptor blocking properties (greater D_2-D_1 ratios than phenothiazines or thioxanthenes) are now under way with the same group of patients.

Associations Among Plasma Prolactin Levels, Tardive Dyskinesia, and Paranoia in Treated Schizophrenics: Relevance to Supersensitivity Psychosis

John G. Csernansky, M.D.,[1] Sophia Vinogradov, M.D.,[1] Elisabeth Prosser, M.D.,[1] Jonathan Kaplan, M.D.,[1] Philip A. Berger, M.D.,[1] and Leo E. Hollister, M.D.[1]

Introduction

Schizophrenics who are exposed to chronic neuroleptic treatment may develop supersensitivity of their brain dopamine (DA) receptors. This is thought to occur when increases in the number of DA receptors develop as an adaptation to neuroleptic-induced receptor blockade (Burt et al., 1977). No significant change in receptor affinity occurs. Choreoform movements of the face, jaw, tongue, and extremities, termed tardive dyskinesia, are felt to be the clinical consequence of DA receptor supersensitivity (DS) development in the nigrostriatal DA pathway, (Klawans et al., 1980). Rapid relapse following neuroleptic dose decrease or withdrawal and the need for steadily increasing neuroleptic doses to maintain remission (i.e., supersensitivity psychosis) may be the result of an analogous development of DS in the mesolimbic DA pathway, (Ungerstedt & Ljundberg, 1977; Davis & Rosenberg, 1979; Chouinard & Jones, 1980). Finally, if DS develops in the tuberoinfundibular DA pathway, tolerance to the prolactin-elevating effects of neuroleptics might occur (Brown, 1983).

Changing Prolactin Levels as a Marker for Supersensitivity Psychosis

A peripheral marker for the putative supersensitivity psychosis syndrome is needed because the clinical characteristics of the syndrome are difficult to distinguish from the natural course of schizophrenia. Decreasing blood prolactin levels during chronic neuroleptic treatment (i.e., tolerance to neuroleptic-induced elevation) may be such a marker. However, it remains controversial whether or not tolerance develops to the prolactin-elevating effects of neuroleptics.

Many investigators have observed that chronic schizophrenics despite continuing treatment have prolactin levels within the normal range (Beumont et al., 1974; De Rivera et al., 1976; Csernansky et al., 1983). This suggests that tolerance does occur; however, prospective studies have yielded mixed results. Both Meltzer and Fang (1976) and Gruen et al. (1978) have found continued elevation of blood prolactin levels after 1 to 3 months of neuroleptic treatment. However, Brown and Laughren (1981) found that prolactin levels rose and then fell during 4 months of neuroleptic treatment. Prospective studies lasting 6 months or more may be needed to resolve this conflict.

Correlations Among Prolactin, Tardive Dyskinesia, and Clinical Symptoms During Treatment

If DS develops concurrently in the various brain DA pathways, correlations among prolactin levels, tardive dyskinesia, and clinical symptoms suggestive of supersensitivity psychosis may occur. We measured plasma prolactin levels, neuroleptic activity (using a radioreceptor assay), abnormal movements, and clinical symptoms in 33 male Research Diagnostic Criteria-positive schizophrenics during neuroleptic treatment.

The patients' plasma prolactin levels were almost entirely within the normal range for males (mean ± SD, 4.4 ± 2.8 ng/ml, highest value 15.2 ng/ml). Prolactin index values, calculated on the ratio of plasma prolactin to

---

neuroleptic activity (measured by radioreceptor assay), were used as individual patient measures of tuberoinfundibular DA sensitivity corrected for a given amount of circulating neuroleptic activity. Prolactin levels ($r(s) = -.38$, $p < .03$) and prolactin index values ($r(s) = -.56$, $p < .001$) were inversely correlated with age, a variable we interpreted as an indirect measure of neuroleptic exposure. Plasma prolactin levels were not significantly correlated with either tardive dyskinesia or clinical symptoms in any of these patients. However, in a subgroup of these patients less than 45 years of age ($n = 19$), prolactin index values were inversely correlated with tardive dyskinesia ($r(s) = -.56$, $p < .03$), assessed using the Gerlach (1979) scale, and the hostility-suspiciousness subscale of the Brief Psychiatric Rating Scale (Overall, 1974) ($r(s) = -.56$, $p < .03$). We interpreted the presence of residual paranoid symptoms in these treated patients as consistent with the presence of supersensitivity psychosis. A more detailed report of this experiment is published elsewhere (Csernansky et al., 1986). In summary, a lower ratio of blood prolactin to neuroleptic levels may be a useful marker to identify patients during treatment who have tardive dyskinesia or characteristics of supersensitivity psychosis. Further research is needed.

TABLE 1. Operational Criteria for Supersensitivity Psychosis (A through C are required).

A.______ At least 6 months of uninterrupted neuroleptic treatment.

B.______ At least one of the following is present for probable, two for definite:

______1) Maintenance neuroleptic dose has steadily increased.

______2) Psychotic symptoms develop repeatedly during uninterrupted neuroleptic treatment and improve after dose increase.

______3) Psychotic symptoms develop rapidly when neuroleptics are withdrawn or the dose is decreased and improve upon restitution of previous therapy.

C.______ None of the following is present:

______1) Non-compliance with neuroleptic medication or substance abuse are usual precipitants of psychotic relapse.

______2) The patient has a neurological disorder, such as a progressive dementia.

Supersensitivity Psychosis: ___Definite ___No
___Probable ___Not determinable

Dates covered
by chart review: ___/___/___ to ___/___/___

Operational Criteria for Supersensitivity Psychosis

As a further adjunct to the study described above we examined the hospital records of 26 of the 33 schizophrenic patients. Using the operational criteria shown in Table 1, we attempted to classify the patients as having definite, probable, or no supersensitivity psychosis. In addition, we allowed the chart examiner to note if the record was incomplete and classification impossible. The criteria emphasized two major components of the supersensitivity psychosis syndrome: need for increasing neuroleptic dose (tolerance) and rapid relapse (dependence).

The two raters (one psychiatrist and one trained research assistant) scored the records independently. To determine the interrater reliability of these classification criteria, numerical scores were assigned to the various groups as follows (definite = 3, probable = 2, no = 1). Then a Spearman rank order correlation was calculated for the two raters. This indicated a surprisingly good agreement ($r(s) = .67$, $p < .001$, $n = 24$). Only 2 records could not be classified by the raters.

However, no significant correlation was found between each patient's supersensitivity psychosis criteria score and tardive dyskinesia, paranoia, or prolactin levels when the entire group, or when only patients less than 45 years of age ($n = 13$) were examined. Thus, a review of hospital records using these criteria for supersensitivity psychosis did not appear to identify patients with current evidence of DS characteristics (i.e., paranoia, tardive dyskinesia, lower prolactin, or prolactin index values). Further research is needed to validate the existence of the supersensitivity psychosis syndrome, and to identify patients who have it.

Basic and Clinical Studies of Neuroleptic-Induced Supersensitivity Psychosis and Dyskinesia

Bruce I. Diamond, Ph.D.,[1] and Richard L. Borison, M.D., Ph.D.[1]

Introduction

Chronic neuroleptic treatment can induce a supersensitivity psychosis either when dosage is decreased or discontinued (Chouinard et al., 1978). Analogous to striatal dopamine (DA) receptor supersensitivity underlying tardive dyskinesia supersensitivity psychosis have been postulated to result from mesolimbic DA receptor supersensitivity (Chouinard & Jones, 1980; Davis & Rosenberg, 1979). In animals, striatal DA supersensitivity in response to chronic neuroleptics has been demonstrated behaviorally (Christensen et al., 1976) and by receptor binding studies (Burt et al., 1977). Davis et al. (1978) has shown that DA receptor supersensitivity after chronic neuroleptic treatment also occurs in the mesolimbic system in animals.

Clinically, if neuroleptic treatment results in mesolimbic DA supersensitivity then, according to Davis and Rosenberg (1979), tolerance should develop to antipsychotic drug effects, withdrawal of neuroleptics should result in a rapid relapse, and psychosis should develop in nonschizophrenic patients treated with neuroleptics. Tolerance (Chouinard et al., 1978), rapid relapse (Chouinard & Jones, 1980; Ekblom et al., 1984), and psychosis in nonschizophrenic individuals as a result of neuroleptic treatment have been shown (Sale & Dristall, 1978; Witschy et al., 1984).

Other issues surrounding supersensitivity psychosis include the effects of anticholinergic drug activity on withdrawal symptomatology, the association of supersensitivity psychosis with tardive dyskinesia, and the development of DA supersensitivity in the tuberoinfundibular system. Luchins et al. (1980) and LaCoursiere et al. (1976) attribute the withdrawal symptoms of restlessness, agitation, insomnia, and anxiety to cessation of anticholinergic effects. However, there is no doubt that high potency neuroleptics without anticholinergic activity can produce withdrawal symptoms (LaCoursiere et al., 1975) and, in fact, neuroleptics with anticholinergic properties may show even less withdrawal symptoms due to a cholinergic rebound (Chouinard & Jones, 1982).

The proposal that both supersensitivity psychosis and tardive dyskinesia are the result of neuroleptic-induced supersensitive DA receptor sites in different brain regions argues in favor of their coexistence within the same individual. Notwithstanding, it has been suggested (Chouinard & Jones, 1982) that supersensitivity psychosis occurs in good prognostic patients while tardive dyskinesia occurs more often in patients with poor prognosis. Moreover, high prolactin levels have been proposed to be associated with supersensitivity psychosis (Chouinard & Jones, 1980). Thus, in this paper both basic and clinical studies were performed to help elucidate neuroleptic-induced DA supersensitivity psychosis.

Methods

Basic Studies

In order to determine the effectiveness of different neuroleptics to act on striatal and mesolimbic DA receptor functions, animal studies were performed. Sprague-Dawley male rats (250–300 g) housed individually with free access to food and water were used. Under pentobarbital anesthesia (35 mg/kg; i.p.) bilateral stainless steel cannulae were placed into either the caudate nucleus or nu-

cleus accumbens using the coordinates from the atlas of Pelligrino and Cushman (1967). Drug infusions (0.5 ml/min) were made using a microliter syringe in freely moving animals and behavior quantitated by rating scales (Diamond et al., 1984).

In other studies 14–day (i.p.) treatment with either clozapine (20 mg/kg) or chlorpromazine (30 mg/kg) to rats receiving amphetamine (AMP) (3.7 mg/kg; i.p.) for 6 weeks (3 weeks prior to, 2 weeks during, and 1 week after neuroleptic treatment) was conducted. Stereotype behavior was quantitated before, during, and after neuroleptic treatment.

Clinical Studies

Twenty-three chronic schizophrenic male patients, after signing informed consents, participated in these studies. The patients were stable for at least 2 months on various neuroleptics. The age range was 34 to 56 years with a mean age of 42.6 years. In one study antipsychotic medication was abruptly discontinued in 12 patients. After a week washout clozapine was administered for 9 weeks which included a 5-day buildup to 200 mg daily. Another 1-week washout period followed the clozapine treatment.

In the other study seven patients were receiving thioridazine and four were receiving haloperidol. Four patients were on 800 mg/day, one on 400 mg/day, and two on 150 mg/day of thioridazine while one was on 25 mg/day, two on 15 mg/day, and one on 2 mg/day of haloperidol. Thioridazine and haloperidol were discontinued by gradually reducing the dosage. Patients remained drug-free for 5 days followed by reinstatement of the original drug and dosage.

In both studies psychopathology was evaluated and rated using the Brief Psychiatric Rating Scale (BPRS) and tardive dyskinesia by the Abnormal Involuntary Movement Scale (AIMS). In some patients serum prolactin was measured using radioimmunoassay.

Results

Basic Studies

The administration of DA (100 mcg) into the nucleus accumbens of rats produced an increase in locomotor behavior. These animals made 35 ± 6 crossings in 10 minutes compared to 12 ± 3 crossings for saline controls. When DA was applied to the caudate nucleus animals exhibited stereotyped grooming, sniffing, headbobbing, and gnawing. They were rated 3.5 ± 0.4 during the subsequent 30-minute period. Pretreatment with systemic clozapine and thioridazine inhibited, in a dose related manner, intralimbic locomotion induced by DA (Table 1). Haloperidol (0.2 to 1 mg/kg) did not demonstrate this dose effect with the doses used. In contrast, haloperidol did show a dose-related inhibition of stereotypy when DA was applied to the caudate nucleus (Table 1). Similar results (Table 1) also were observed for clozapine and thioridazine in striatal DA mediated stereotyped behavior. Thus, as can be readily observed from Table 1 all three neuroleptic drugs preferentially inhibit limbic before striatal DA effects.

In animals treated chronically with AMP, stereotypy scores before neuroleptic administration were 3.5 ± 0.2. Chlorpromazine treatment inhibited AMP stereotypy less effectively over the 14-day period (Table 2). Thus, tolerance appeared to develop. Although clozapine failed to significantly inhibit, AMP stereotypy the trend of tolerance was apparent (Table 2). Upon cessation of chlorpromazine there was a significant increase in AMP behavioral scores over pre-chlorproma-

+ Potentiation

zine ratings. This lasted for 3 days (Table 2). Clozapine withdrawal did not affect significantly AMP stereotypy (Table 2).

Clinical Studies

The mean BPRS score of the 12 clozapine patients during the washout period preceding the administration of clozapine was 26.2 ± 6.3. By the end of the first 2 weeks of clozapine treatment the mean score had fallen to 20.7 ± 6.8. This level of improvement continued throughout the clozapine treatment phase. At the end of the 1-week clozapine withdrawal period, the BPRS score was 30.3 ± 14.4. None of these mean BPRS scores were significantly different from each other. However, when the data were separated into those that exhibited a worsening of symptomatology following clozapine withdrawal, half the patients were worse after clozapine withdrawal. In fact, five of six patients that did not worsen had lower BPRS scores after clozapine withdrawal which ranged from 10 to 27 percent improvement over pre-clozapine scores. However, the average improvement was not statistically significant. In contrast, the group with higher post-clozapine BPRS scores from pre-clozapine scores showed a significant difference ($p \leq 0.05$). Four of these six patients demonstrated a greater than 20 percent worsening. The percent of worsening ranged from 17 to 126 percent. There were only 2 of 12 patients that had tardive dyskinesia. The AIMS score of these two patients was not modified by either clozapine treatment or withdrawal.

In Figures 1 and 2 the results of seven patients on thioridazine are shown. Only two patients had their BPRS score increase 20 percent or more when the dose of thioridazine was decreased. However, in six of seven patients, ratings of psychosis were worse during the drug washout period ($p \leq 0.025$). When the original dose of thioridazine was reinstated the mean BPRS score was within 6 percent of the original thioridazine baseline score. In fact, only two patients who got worse had scores above 10 percent of their original score. Patient G had an unusual and opposite effect when thioridazine was discontinued and reinstated (Figure 2).

Table 3 shows the mean and standard deviation of the BPRS score in four patients receiving haloperidol. When haloperidol was withdrawn, there was a significant increase ($p \leq 0.05$) in the BPRS score which returned to the pre-drug score when haloperidol was reinstated. Within this group of four patients reinstatement of the original dose of haloperidol did not modify the psychopathology observed during the washout period in one patient.

The discontinuation and reinstatement of thioridazine and haloperidol on dyskinesias

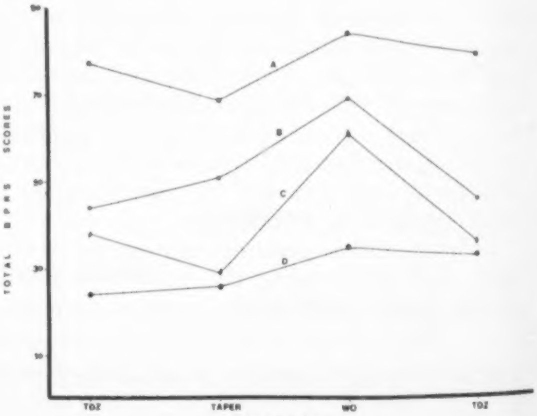

FIGURE 1. The total Brief Psychiatric Rating Scale (BPRS) score of four patients (A,B,C,D) on thioridazine (TDZ), during dose reduction (taper), washout (WO), and thioridazine reinstatement (TDZ).

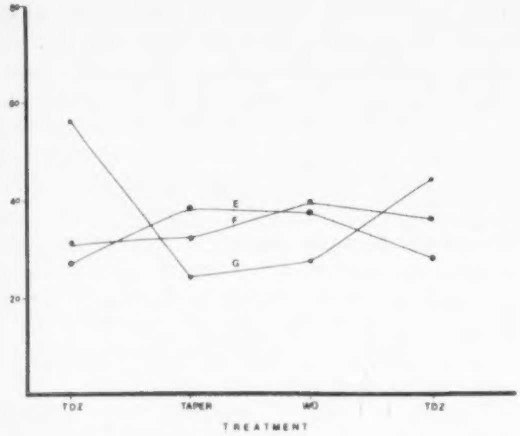

FIGURE 2. Patients (E,F,G) total Brief Psychiatric Rating Scale (BPRS) score on thioridazine, during dosage reduction (taper), washout (WO), and reinstatement of thioridazine (TDZ).

was not unusual except for two patients who improved when haloperidol was discontinued. These results are presented in Table 4.

If one compares the AIMS against the BPRS scores, there are only three cases where both did not worsen during drug withdrawal: two patients on haloperidol where the dyskinesias improved and one patient on thioridazine whose psychosis improved.

Serum prolactin was measured in patients on thioridazine, during washout and when the original thioridazine dose was reinstated. The mean serum prolactin level while on thioridazine was 20.0 ng/ml range 4.6 to 32.6 ng/ml. During the washout period mean prolactin levels fell to 5.5 ng/ml with a range between 4.6 to 6.6 ng/ml. When thioridazine was readministered at its original dose, serum prolactin levels were higher than the original drug period (32.7; range 9.9 to 51.7; ($p \leq 0.05$).

Discussion

Supersensitivity psychosis has been postulated to be the result of an underlying DA receptor site sensitivity in the mesolimbic system, whereas in tardive dyskinesia DA supersensitivity within the extrapyramidal system probably is the causative factor. Since neuroleptic drugs are dopamine receptor blockers, supersensitivity psychosis and dyskinesia should be produced equally by all neuroleptics. However, Chouinard and Jones (1982) suggest that neuroleptics with anticholinergic activity should mask the withdrawal psychosis and demonstrated that supersensitivity psychosis occurs with high potency neuroleptics (Chouinard & Jones, 1980). Notwithstanding, it has been reported (Ekblom et al., 1984) that clozapine, an antipsychotic drug with high anticholinergic activity, produces supersensitivity psychosis in schizophrenic patients. This same argument about the anticholinergic activity of neuroleptics or lack of it in individuals predisposed to tardive dyskinesia is often cited (APA Task Force, 1980). Thus, clozapine usage leads to few cases of tardive dyskinesia in contrast to high potency neuroleptics (Gerlack & Summelsgaard, 1978). The administration of clozapine, thioridazine, or haloperidol to the mesolimbic and striatal brain areas of rats, in this paper, demonstrated that the anticholinergic property of a neuroleptic is not important in blocking the effects of DA. The only difference between these three drugs was potency. However, clozapine never completely blocked DA in the striatal system. By extrapolation higher doses should, but in likelihood would exceed those concentrations used clinically. These results support receptor binding studies in human and rat brain where these neuroleptics, within a similar concentration range, inhibited ^{3}H-spiroperidol binding in the limbic system but not the extrapyramidal system (Borison et al., 1981). The failure of clozapine to significantly block chronic AMP stereotypy where striatal DA receptor site numbers are increased (Borison et al., 1979) supports the differential action of clozapine. Further evidence to support the fact that low and high potency neuroleptics are equipotent in inducing supersensitivity or mesolimbic psychosis are the results that clozapine, thioridazine, and haloperidol were capable of doing so in this study and clozapine (Ekblom et al., 1984) and fluphenazine (Chouinard & Jones, 1980) in other studies.

Features of supersensitivity psychosis include tolerance to antipsychotic drug effects and relapse after drug withdrawal (Davis & Rosenberg, 1979). Both of these effects were observed in rats chronically treated with AMP and administered either clozapine or chlorpromazine for 14 days (Table 2). The lack of significant antagonism and subsequent rebound increase in AMP stereotypy observed with clozapine is probably due to its absence of significant striatal DA blocking properties, since chronic amphetamine is known to produce striatal DA supersensitivity (Klawans & Rubovits, 1972). If one examines the effect of chlorpromazine withdrawal on AMP stereotypy there is not only a relapse but a rebound increase of behavioral stereotypy compared to pre-chlorpromazine scores. This rebound worsening or relapse occurs in the mesolimbic system and is supported clinically by the clozapine results whereby 50 percent of the patients exhibited worse BPRS scores after clozapine withdrawal.

The issue of relapse as a feature of supersensitivity psychosis is one surrounded by controversy, since a differentiation between the active underlying psychopathology and the drug effect has to be made. In Figures 1 and 2 patients A, B, and G had initial BPRS scores above 40 while on drug, indicative of active pathology. However, upon drug withdrawal patient G improved dramatically and worsened when thioridazine was reinstated. Obviously this patient did not have supersensitivity psychosis but a psychosis due to the drug. One patient after haloperidol withdrawal continually worsened even after haloperidol was reinstated. Ideally, supersensitivity psychosis drug withdrawal studies should be extended in a drug-free condition for as long as possible so that its course can be observed (Weinberger et al., 1981).

Tolerance was observed in patients (A,B,D,E,F) on thioridazine and one patient on haloperidol if one assumes that when the original dose was reinstated the BPRS scores were slightly higher than before drug discontinuation. This phenomenon of higher values on the same drug and dosage after washout compared to before washout was observed for prolactin levels in patients on thioridazine. Thus, it appears that in these patients supersensitivity develops in the tuberoinfundibular system as well.

If the pathology of tardive dyskinesia and supersensitivity psychosis differs only in the anatomical area involved, then patients with both should have concomitant changes in their BPRS and AIMS scores. Except for three patients this occurred. Unlike tardive dyskinesia, reports of supersensitivity psychosis are rare in individuals without schizophrenia. This may be due to the lack of knowledge about supersensitivity psychosis or that an abnormal DA state in the mesolimbic system is a necessary prerequisite for this to develop. However, animal studies argue against this latter point of view. There are several questions that are often asked about tardive dyskinesia, on the reversibility, incidence and other characteristics, that need to be also answered for supersensitivity psychosis by future studies.

Corticotropin-Releasing Hormone—A New Tool to Investigate Hypothalamic-Pituitary-Adrenocortical Physiology in Psychiatric Patients

Florian Holsboer, M.D., Ph.D.[1]

The recent sequencing and subsequent synthesis of ovine corticotropin-releasing factor (o-CRF) by Vale et al. (1981) and its human analog by Shibahara et al. (1983) opened the possibility to study pathophysiology underlying several aberrancies of the pituitary-adrenocortical system in psychiatric illness. Since hypersecretion of corticosteroids represents one of the most extensively studied abnormalities among depressed patients, it was intended to investigate by means of o-CRF or human CRH infusions whether hypercortisolemia can be attributed to a central nervous system disturbance.

Clinical Studies Employing Ovine CRF

A dose of 100 µg ovine CRF was infused to eight drug-free patients with endogenous depression. Their maximum corticotropin (ACTH) output was indistinguishable from a comparison sample of normal controls (Holsboer, 1983; Holsboer et al., 1984a). This was taken as support that an enhanced responsiveness of pituitary corticotrophs at the anterior pituitary is not likely to account for excessive pituitary adrenal activity. The failure of a consistent relationship between response of ACTH and a variety of adrenal corticosteroids following 100 µg o-CRF given at 9 a.m. with a multisteroid assessment following synthetic ACTH and subsequently a 1 mg dexamethasone suppression test (DST) further corroborated that a central rather than a peripheral effect is the main factor responsible for HPA-overactivity (Holsboer et al., 1984a). Subsequently o-CRF responses of the pituitary-adrenal system were recorded in 16 depressed patients who were further classified according to their DST status, registered after the o-CRF challenge. The net ACTH and cortisol release pattern between DST suppressors and nonsuppressors was indistinguishable between both groups (Holsboer et al., 1984b). Also, o-CRF induced ACTH, cortisol and corticosterone output in eight depressed nonsuppressors on the DST was unchanged when these individuals were retested after return to euthymia and DST suppression (Holsboer et al., 1985a). Based on these findings, it was hypothesized that neither enhanced responsiveness of the pituitary nor the adrenal gland is a pathophysiological correlate of DST nonsuppression.

Clinical Studies Employing Human CRH

When the human analog of CRF (h-CRH) became available in 1984 the study protocol was changed and the h-CRH infusions were performed at 7 p.m. This study design promised to reveal more subtle differences in hormonal response, since Copinschi et al. (1983) suggested that CRH stimulation tests performed during the quiescent period of the pituitary-adrenal system may be advantageous to discriminate between normal and subnormal corticotropic function.

After a standard calorie and electrolyte balanced lunch at 11:30 a.m., all depressed patients and normal controls received an intravenous catheter connected with an extension through a sound proof lock into an adjacent room where plasma for cortisol analysis was collected every 20 minutes between 2 p.m. and 7 p.m. At 7 p.m., 100 μg h-CRH reconstituted in 1 ml 0.02 percent HC1 in 0.9 percent saline was directly injected into the cannula and plasma for ACTH and cortisol assessment was sampled according to the time points given in Figure 1. The major finding of this study was a blunted response of ACTH in depressives, which was associated with enhanced release of baseline cortisol levels prior to h-CRH infusion (Holsboer et al., 1984c). Interestingly, the cortisol release patterns remained indistinguishable between both comparison groups, indicating that after prolonged hyperstimulation by ACTH and possibly by other adrenal growth factors the adrenocortical cells may develop a mild functional hyperplasia. Such a phenomenon is also present in endocrine diseases associated with an ACTH excess such as ACTH-dependent Cushing-syndrome or congenital adrenal hyperplasia. These study results were amplified by the data of Gold et al. (1984) who reported in their comprehensive review that following ovine CRF, depressives have an attenuated ACTH response when contrasted to manics, schizophrenics, or normal controls. Since there is evidence that aldosterone regulation is impaired in depression (Hullin et al., 1981; Holsboer et al., 1982) a study was conducted which compared aldosterone response to h-CRH in eight depressives and eight matched controls with ACTH, cortisol, and corticosterone response. In agreement with previous studies from our laboratory (Holsboer et al., 1984c, Holsboer et al., 1986a) and those by Gold et al. (1984) ACTH output was decreased in depressives, while cortisol and corticosterone release was normal. However, we found a significantly blunted aldosterone release induced by h-CRH (Figure 2). Differential effects of h-CRH to glucocorticoid and mineralocorticoid release may provide a clue to understanding the reported disturbance of electrolyte homeostasis in patients with affective disorder.

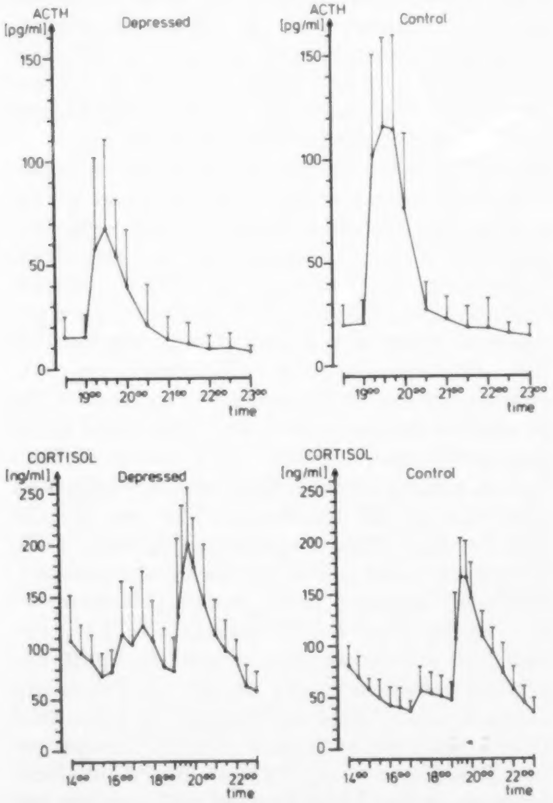

FIGURE 1. Effect of h-CRH on plasma ACTH and cortisol release in normal controls and depressed patients.

h-CRH-Challenges in Dexamethasone Treated Depressives and Controls

DST nonsuppression of ACTH and cortisol was originally regarded as a peripheral outprint of a centrally mediated overdrive of

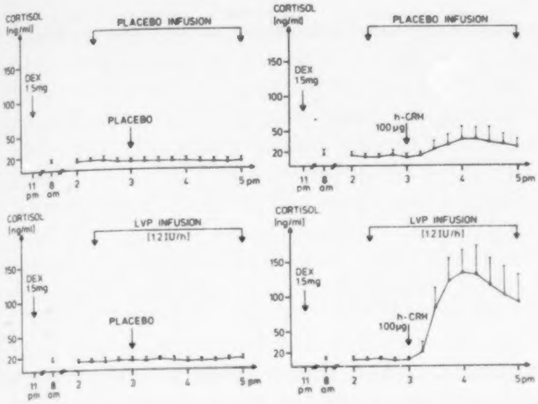

FIGURE 2. Effect of placebo, h-CRH, LVP, and a combined h-CRH/LVP administration upon plasma cortisol in normal controls pretreated with 1.5 mg dexamethasone.

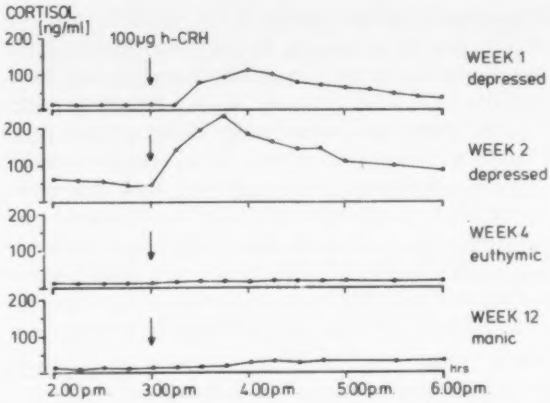

FIGURE 3. Plasma cortisol response in a dexamethasone pretreated patient following h-CRH at different clinical conditions.

CRH (Carroll et al., 1976). To further explore the pathophysiology underlying DST resistant cortisol levels in depression we compared pituitary-adrenal response to placebo, h-CRH or lysine vasopressin (LVP) with a concurrent application of both neuropeptides after pretreatment with 1.5 mg dexamethasone in six normal male controls (von Bardeleben et al., 1985). As shown in Figure 3, LVP infusion (1.2 IU/h) given in the afternoon failed to provoke ACTH and cortisol elevation. Also an h-CRH bolus administered at 3 p.m. induced only a modest release of ACTH and cortisol above hormone levels observed after placebo infusion. However, if both peptides were administered in combination, a substantial escape of plasma cortisol from dexamethasone suppression became apparent. Since ACTH levels increased in parallel with cortisol it was concluded that LVP synergizes the effect of h-CRH at pituitary corticotrophs to override dexamethasone suppression. In line with this finding is a recent study by Nemeroff et al. (1984) who measured CRH in cerebrospinal fluid and observed elevated levels in major depression which were not related to their DST status. This questions that elevation of CRH alone is sufficient to explain DST resistance and suggests that other factors including synergizing neuropeptides, activity of neural pathways and changes at feedback receptor levels are corequired.

In contrast to normal controls, depressed patients pretreated with dexamethasone responded to CRH with increased cortisol release (Figure 4). This phenomenon was observed in DST suppressors as well as in DST resistant patients. When retesting these individuals several times during the course of their illness and again either following recovery or a switch into mania, it was observed that h-CRH gradually failed to produce cortisol surges after depressive symptomatology has entirely resolved. Whereas in normals the dexamethasone bioavailability achieved by administering 1.5 mg dexamethasone is obviously sufficient to prevent pituitary-adrenal stimulation by CRH, this seems not to be the case for depressives, even if dexamethasone plasma concentrations add to nonsuppressed endogenous cortisol levels. This suggested that in depression the negative feedback receptors at the pituitary, the hypothalamus and the hippocampus, become subsensitive to corticosteroids in depressed patients. When central regulation returns to normalcy there is a stepwise increase of receptor sensitivity resulting in an adrenocortical response to CRH which is indistinguishable from that in normal controls. This tentative conclusion is in line with several recent observations. Carr et al. (1984) reported a paradoxical increase in ACTH levels after infusion of cortisol to endogenously depressed patients indicating that glucocorticoids may produce stimulatory as well as inhibitory effects on ACTH release. While active stress or steroid administration is able to decrease the corticotrophic cell sensitivity to CRH, chronic stress leads to normal or increased sensitivity. Young and Akil (1985) employed anterior lobe cultures from chronically stressed rats and showed that subsensitivity to steroid negative feedback at the pituitary can develop since these animals release increased ACTH after CRH and have increased ACTH pituitary contents despite the known inhibitory effects of corticosteroids upon ACTH biosynthesis and release. In addition McEwen (1985) has recently reviewed the diverse regulatory effects which glucocorticoids exert upon brain neurotransmission and emphasized that the hippocampus, which is an important site for glucocorticoid negative feedback, develops subsensitivity to these steroids following prolonged overexposure. Conceivably then, hypercortisolemia may induce a neuronal loss of steroid sensitive receptors reducing its suppressing inputs upon CRH-ACTH release. Mechanisms of this kind may have considerable physiological significance to explain several different though overlapping phenomena of pituitary-adrenocortical disturbance including hypersecretion of cortisol and abnormal responses to dexamethasone or to a combined h-CRH/DST administration.

h-CRH-Induced Changes of Thyroid Function

Multiple endocrine perturbation tests may provide a set of variables which allows profiling of neural function. This rationale is limited if several neuroendocrine systems would be independent from each other. Besides abnormalities of the pituitary-adrenocortical axis, the reduced thyrotropin (TSH) response following infusion of thyrotropin-releasing hormone (TRH) constitutes the most extensively studied endocrine disturbance among depressives (Loosen and Prange, 1982). We compared ACTH responses following 100 μg h-CRH with TSH responses to 500 μg TRH in 11 patients with major endogenous depression and 11 normal controls (Holsboer et al., 1985b). The time difference between both tests was at least 2 days and basal thyroid status revealed euthyroidism. In agreement with current literature lower TSH output expressed as area under time course curve was found in depressives when compared with controls. A Spearman rank correlation of TSH and ACTH output following specific secretagogues revealed statistical significance ($r = 0.65$, $p < 0.01$). After challenging the pituitary-adrenal axis during sleep with a total of 200 μg CRH during 4 hours (10 p.m. – 1 a.m.), TRH-tests, which revealed that after h-CRH prestimulation TSH responses are blunted, were performed the next morning. These data suggest that the thyroid axis is not independent from pituitary-adrenal activity. Both endocrine axes seem to be, at least in part, under a common control.

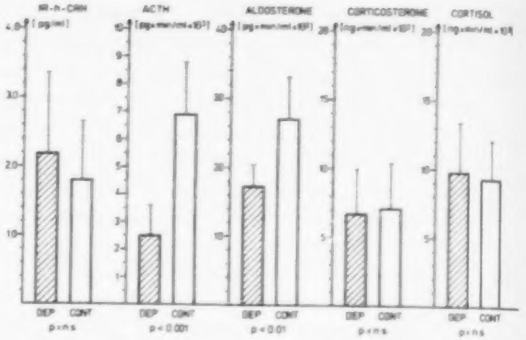

FIGURE 4. ACTH, glucocorticoid, and mineralocorticoid responses (expressed as areas under time course curves ± SD) to h-CRH in normal controls and depressed subjects. Plasma CRH levels measured 15 min after injection were indistinguishable between groups.

h-CRH Induced Sleep-Endocrine Changes

The sleep related secretion of human growth hormone (h-GH) during the first half of total sleep period is regulated by an intrinsic central nervous system mechanism whose precise nature is unknown. At the same time period when nocturnal growth hormone secretion reaches its maximum the cortisol secretion approaches its nadir. Clinical states which are associated with increased levels of endogenous or exogenous corticosteroids are frequently characterized by decreased pituitary growth hormone reserve. To further investigate the interdependency between the physiological growth hormone surge during sleep and pituitary-adrenal activity, 50 μg h-

CRH or placebo was infused four times every hour beginning at 10 p.m. to normal controls, who were adapted to the sleep laboratory and who fell asleep between 11 p.m. and midnight. Blood was drawn every 20 minutes until 7 a.m. to measure cortisol and h-GH. The major finding of this study was a significant blunting of sleep-related h-GH release, indicating that a pituitary-adrenocortical activity may modulate growth hormone release induced by falling asleep. No immediate effects of repetitive h-CRH stimulations upon major sleep characteristics during the first part of the night were observed. However, in the second part of the night, a marked reduction of REM sleep and stages 3 and 4 was recorded, whereas stages 1 and 2 increased. Similarly, Ehlers et al. (1986) showed that in rats an intracerebroventricularly administered dose of h-CRH reduces slow wave sleep drastically and increases the higher frequency contents. The present observation of a more shallow sleep after h-CRH as opposed to placebo suggests that peripheral hormonal overactivity of the pituitary-adrenocortex system contributes to the behavioral phenomena which are experimentally and perhaps also physiologically evoked by central CRH.

Multiendocrine Assessment in the Dexamethasone Suppression Test

S. Craig Risch, M.D.,[1] David S. Janowsky, M.D.,[1] Lewis L. Judd, M.D.J.,[1] Christian Gillin, M.D.,[1] Mariam Mott,[1] Jeffrey L. Rausch, M.D.,[1] and Leighton Y. Huey, M.D.[1]

Introduction

Adrenal cortisol hypersecretion, as well as flattened cortisol circadian periodicity, and failure to suppress plasma cortisol concentrations with the overnight low-dose Dexamethasone Suppression Test (DST), occur in a significant number of endogenously depressed patients, and have now been well established as substantive neuroendocrine markers highly specific for primary affective disorders (Stokes et al., 1975; Carroll et al., 1976*a*, 1976*b*, 1981; Sachar, 1976; Brown et al., 1979; Sachar et al., 1980; Schlesser et al., 1980). Many investigators also believe that this neuroendocrine abnormality reflects limbic-hypothalamic-hypophyseal hyperactivity.

In this regard, Fang et al. (1981) and Reus et al. (1982) have recently reported that although dexamethasone-resistant depressed patients did not differ statistically from dexamethasone-sensitive depressed patients in pre-dexamethasone plasma adrenocorticotrophic hormone (ACTH) concentrations, the dexamethasone-resistant depressed patients did have significantly higher post-dexamethasone plasma ACTH concentrations than did the dexamethasone-sensitive patients. Kalin et al. (1982) reported that dexamethasone-resistant patients have significantly higher pre- and post-dexamethasone plasma ACTH concentrations than do dexamethasone-sensitive patients.

Yerevanian et al. (1983) failed to demonstrate differences in ACTH plasma concentrations at 4 p.m. or 11 p.m. after dexamethasone in 19 normal volunteers, 10 depressed suppressors, and 19 depressed nonsuppressors. However, they interpreted this lack of significant group differences as reflecting of great interindividual variation in adrenal sensitivity to circulating ACTH among the subjects within each group. In a later study, this group (Yerevanian et al., 1983) reported that among 16 patients with major depressive disorder who were nonsuppressors on the DST upon hospital admission, that there was a significant reduction in plasma ACTH concentrations in patients whose DST normalized with clinical recovery, while ACTH levels remained high in the group that continued to be nonsuppressors.

Thus, these studies suggest that ACTH levels may be elevated in dexamethasone nonsuppressors and that monitoring plasma ACTH concentrations in the DST might be clinically useful.

In addition to suppressing plasma concentrations of cortisol and ACTH, dexamethasone also suppresses plasma concentrations of prolactin. Thus, Meltzer et al. (1982) monitored the plasma prolactin response to dexamethasone in 52 psychiatric patients and reported a significant association between nonsuppression of plasma cortisol and prolactin after administration of dexamethasone.

Thus, we have been studying the clinical utility of monitoring plasma ACTH and prolactin concentrations before and after dexamethasone in psychiatric inpatients on our Affective Disorders Unit at the San Diego Veterans Administration Hospital.

Methods

These studies were conducted with the local human subjects committee approval. All subjects gave written, informed consent. All subjects were male and there were no significant differences in age composition among

---

[1] Department of Psychiatry, School of Medicine, University of California, San Diego, M-003, La Jolla, CA 92093; and San Diego Veterans Administration Medical Center, La Jolla, CA 92161.

experimental and control groups. All subjects received a Schedule of Affective Disorder and Schizophrenia (SADS) and Research Diagnostic Criteria (RDC) diagnosis based on an interview by an experienced diagnostician and collateral information obtained from previous hospitalizations, medical records, and interviews with family members. Diagnostic breakdown of the 28 subjects was as follows: schizoaffective depression = 3, major depression = 10, minor depression = 3, bipolar depression = 4, other = 4, bipolar manic = 3, and schizoaffective manic = 1. No subjects were receiving medications or had medical illness known to interfere with the DST. All subjects were inpatients on the Affective Disorders Clinical Research Unit of the San Diego Veterans Administration Hospital. All subjects received the standard DST as described by Carroll and colleagues (1981). Blood samples for plasma cortisol determinations were obtained at 0800, 1600, and 2300 before and after the 1 mg DST. Blood samples for plasma ACTH and prolactin determinations were only obtained at 0800 and 1600 before and after the DST. Blood was collected in polypropylene EDTA tubes on ice and promptly centrifuged at 10,000 rpm for 20 minutes in a refrigerated centrifuge and plasma was stored in a −80 degree°C freezer until assayed. Subjects whose plasma cortisol concentrations exceeded 5 ug/dl at 0800, 1600, or 2300 after dexamethasone were classified as nonsuppressors.

Assay Procedures

Plasma cortisol concentrations for the DST's were performed in the SDVAMC clinical laboratory using the Becton Dickinson I (125) Cortisol ARIA II System.

Assay sensitivity is 2 μg/dl and upper limit is 64 μg/dl. The intra-assay coefficient of variation is 4.8 to 5.9 percent and the interassay coefficient of variation is 4.9 to 8.6 percent.

Plasma ACTH measurements employed a sensitive RIA system developed and described by Orth and coworkers. This well characterized antiserum has a high affinity ($K_d > 1.07 \times 10^{-12}$ M/liter) and is now commercially available from the IgG Corporation. The antiserum is of polyclonal origin yet it is specifically directed at the steroidogenic NH_2-terminal (1–24) sequence of the whole (1–39) ACTH molecule. Thus, it does not react with nonsteroidogenic COOH-terminal fragments of ACTH that can be found in circulating blood. The optimized RIA system is capable of detecting as little as 5 pg/ml of immunoreactive ATCH while maintaining a working range of 0.5 to 75 pg/tube with excellent precision throughout the standard curve. The working standard ACTH reference preparation for this assay is the synthetic human (1–39) sequence of adrenocorticotropin which is available from Dr. Salvatore Raiti at the National Hormone and Pituitary Program (NIADDK).

Plasma prolactin concentrations were determined in duplicate using a RIA with reagents purchased from Calibiochem Corp. (La Jolla, CA). The double antibody technique was used with human PRL for iodination and standards, and with a rabbit antihuman PRL antibody. The sensitivity of the assay is 0.8 ng/ml with intraassay variation of 5 percent and interassay variation of 8 percent.

Pre-dexamethasone basal and post-dexamethasone changes in neuroendocrine plasma concentrations among groups were determined by mixed analysis of variance. Both raw scores and log transformed neuroendocrine concentrations were analyzed. "Cut-points" using a computerized program derived from Fisher's Exact Test were used to determine sensitivity and specificity of different neuroendocrine changes among groups. Pearson product moment correlations were performed on pre- and post-dexamethasone plasma cortisol, prolactin, and ACTH values.

Results

As expected, in the subject group as a whole, dexamethasone suppressed plasma concentrations of cortisol, prolactin, and ACTH (Table 1).

Subjects were grouped as dexamethasone suppressors or nonsuppressors using post-dexamethasone cortisol values of 5 μg/dl as the discriminating cut-points. Pre- and post-dexamethasone prolactin and ACTH values were compared using a two-factor ANOVA

TABLE 1. Pre- and Post-Dexamethasone Means and Standard Errors for 28 Psychiatric Patients.

	Pre-Dexamethasone			Post-Dexamethasone			
	0800	1600	2300	0800	1600	2300	*p* Value
ACTH pg/ml (N = 25)	25.2 ± 2.9	23.8 ± 2.5	—	14.6 ± 1.7	14.6 ± 1.4	—	.0000
Prolactin ng/ml (N = 22)	16.9 ± 1.3	14.1 ± 1.2	—	12.6 ± 1.1	13.4 ± 1.0	—	.0000
Cortisol µg/dl (N = 24)	17.5 ± 1.2	11.8 ± 1.0	6.4 ± 1.5	3.2 ± 0.7	3.5 ± 0.6	3.2 ± 0.4	.0000

with one repeated measure to assess group differences (suppressors vs. nonsuppressors) over time.

No significant group-by-time interactions for ACTH or prolactin were found when all pre- and post-dexamethasone time points were used.

However, a significant group by time interaction was found for raw ACTH scores when the 2 post-dexamethasone times were compared for the 2 groups (Table 2) ($F(1,25) = 5.56, p < .05$) as well as log-transformed values ($F(1,25) = 10.00, p < .005$). No such significant interaction was found for prolactin.

Simple effects tests were performed post-hoc on ACTH values to determine if changes over time for each group and differences between groups at each time were significant.

No significant positive correlations were noted in pre-dexamethasone basal or post-dexamethasone changes among cortisol, prolactin, and ACTH.

A "cut-point" Fisher's Exact Test of ACTH 19.0 pg/ml at 1600 post-dexamethasone significantly differentiated bipolar depressed and major depressed patients from all other subjects (Table 3). A cut-point of cortisol 8.8 µg/dl, at 1600 pre-dexamethasone significantly differentiated bipolar depressed and major depressed patients from all other subjects (Table 3). Cut-points of prolactin 20.1 ng/ml at 0800 pre-dexamethasone and 14.6 ng/ml at 1600 post-dexamethasone significantly differentiated bipolar depressed and major depressed patients from all other subjects (Table 3).

TABLE 2. Post-Dexamethasone Means and Standard Errors for ACTH in Subjects Who Did and Did Not Suppress Cortisol.

	0800	1600	*N*	*F* Value	*p* Value
Suppressors	16.1 ± 2.3	14.4 ± 1.8	17	5.56*	.0265
Nonsuppressors	12.8 ± 2.0	16.2 ± 2.2	10		

*Reported *F* value (*df* = 1,25) is for the group by time interaction.
